The circuits connecting the distributing board with the different stations are in some places of bare copper on porcelain insulators, and in other places they are of insulated cable running under the platforms of the stations. All the distributing circuits, whether for light or power, when they leave the distributing boards at the various railway stations are run along the spring of the roof; these circuits, like the main circuits, are run on porcelain insulators. Wood-casing has only been employed in rare cases and dry places. As an instance of the amount of light required, it may be remarked here that the Luxembourg station requires light for 21 hours out of the 24, and that the entire electric lighting plant is looked after by one electrician and one machinist, the switching in and out of the lamps at the various stations being done by the regular employés of the railway company. In order to avoid the necessity of employing men at the time when the light is not required, the carboning of the lamps is carried out whilst they are in circuit, each lamp being provided with a short-circuit switch to permit of this, the current through the remaining three lamps in the series being temporarily increased thereby.

A few details with regard to the electrically-driven apparatus will be interesting. First of all comes the ventilator devoted to the ventilation of the Luxembourg station, and the tunnel between this station and the Port Royal station. This ventilator has to run continually, and the current is supplied to it straight from the machines; it runs at 70 revolutions per minute, and is belt-driven by a 15-H.P. series motor running at 260 revolutions. The motor is started by means of a switch at the switchboard which operates a liquid resistance, the apparatus being arranged so as to short-circuit the rheostat, whilst its electrodes are completely within the solution, an arrangement which is preferable to the one which acts by making the short circuit occur inside the vessel itself. Another electrically-driven apparatus is a centrifugal drainage pump which is situated at the Luxembourg station. The motor driving this pump also receives its current straight from the dynamos. The turn-tables at the Luxembourg station are driven by an endless chain, the chain being driven by an electric motor. The starting and stopping is carried out by means of a pedal acting on a relay which sends the current through a resistance; as soon as the motor has got up speed the resistance is automatically switched out by means of a second relay. These turn-tables do a considerable amount of work, one of them being used about 80 times a day. The semi-rotation of the turn-table with a 50-ton locomotive on it is carried out in less than 30sec. Quick working of the turn-tables is very important at the Luxembourg station. Lifts are used at the Luxembourg and Denfert stations to take the passengers and their luggage to the surface. The arrangements in each of these two cases are the same. These lifts are capable of lifting a load of 700 kilograms ($\frac{3}{4}$ths of a ton) at a speed of 0·45 metres per second ($1\frac{1}{2}$ft.). The lifts are suspended by ropes taken round drums which are electrically driven by means of a tangential screw. The starting and stopping of the lifts is effected by means of a resistance actuated by a cord running through the lift. The lifts were made by the firm of Edoux. The lifts and turn-tables are supplied with current from two batteries of accumulators, one of which is placed on either branch of the three-wire system, one battery being at the generating station and supplying current to the lifts at the Denfert station and the Mont Rouge turn-table, the other supplying current to the Luxembourg lifts and the turn-table at that station, this latter battery being placed under the platform of the Luxembourg station. The accumulators are charged through a continuous-current transformer, the potential at the secondary terminals of which is regulated by means of a resistance in the primary circuit. The use of batteries for supplying the current to the lifts and turn-tables prevents injurious shocks to the generating machinery. The application of electricity which has been made at the Luxembourg station only remains to be mentioned. The walls of the underground portion are decorated with ornamental white porcelain panels, which give the place quite an artistic appearance and serue to reflect the light of the arc lamps.

ECONOMY AND ACCUMULATORS.

BY ED. W. COWAN.

Mr. Howell, in his Paper on "The Uses of Accumulators" (*see* p. 224), read before the Northern Society of Electrical Engineers on May 13th, claimed to be able to effect a saving of £13 per day on the coal bill by the installation of a battery of accumulators in a certain American electricity supply station. In the discussion which followed an endeavour was made to challenge this figure, but the criticisms did not convince either Mr. Howell or Mr. Crompton. It is proposed in

Digitized by Google

this article to examine the question rather more fully, in the hope that it may be definitely settled. The use of accumulators in an electricity supply station has become a very important matter, and it is therefore well worth careful consideration.

Below are given the two load diagrams (Figs. 1 and 2) which Mr. Howell used to illustrate his Paper. Fig. 1 shows the actual load diagram for June 23rd of the American station, and how that load was dealt with by the steam dynamos installed. Fig. 2 shows the load diagram transformed by the same steam dynamos, working in conjunction with a battery having a total output of 14,000 ampere-hours. Between these diagrams Mr. Howell estimates a difference of £13 worth of coal, taking it at 20s. per ton, in favour of the use of accumulators. This contention is not disputed; Mr. Howell has evidently very carefully worked out the steam consumption for each engine, based upon Mr. Willans' curves of steam economy in relation to load. But the important point is this: is the saving of fuel due to the installation of the battery of accumulators? In order to test this point let us remind ourselves what quality it is which an accumulator possesses which adapts it to being used as a means of economy in an electric supply station. It is this: that it is a reservoir into which electrical energy can be stored when it can be generated at a low fuel cost, and from which a supply can be obtained when its generation first hand would be expensive. We are therefore brought to this point—that all the saving effected must be made upon the electricity which passes into and out of the battery.

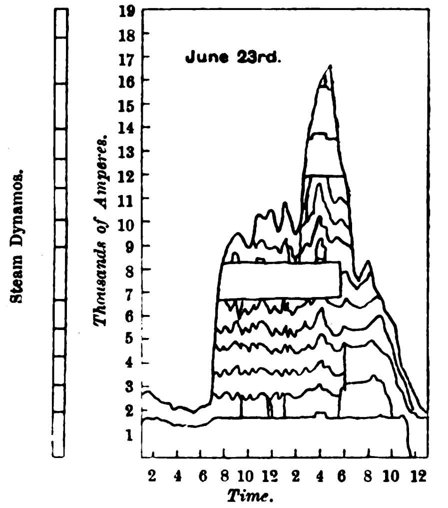

Fig. 1.—Without Accumulators.

Measuring the diagram it will be found that the battery only deals with about 1,520 units. The coal cost of this output of units under the conditions of load obtaining in this station could hardly amount to more than 1d. per unit, or a total of £6. 6s. 8d. if supplied direct to the circuits. Where, then, is the saving of £13 to be made? Mr. Crompton and Mr. Howell both replied that it was made partly on the electricity dealt with by the battery, but chiefly on the electricity supplied by the steam dynamos which went direct to the circuits, pointing out that as the steam dynamos were run always at full load the consumption of steam per unit was reduced not only on the units which went to charge the cells, but on the whole output of the plant.

This sounds plausible, but it is contended that it is not and cannot be true. For the purpose of considering the question, the steam consumption of each unit of plant should be divided into three parts (Fig. 3). The area of A represents the steam consumed in overcoming the standing losses of the engine and dynamo, the area of B, the steam consumed in generating the units which are supplied direct to the circuits, and the area of C the steam consumed in generating the units which are stored in the battery. Now, this diagram is properly divisible into two parts, in order to ascertain whether the addition of the battery can effect any economy on the electricity supplied direct to the circuits. The first part is A + B, which represents the steam consumed for the output to the circuits direct, and which would be the same whether an additional output represented by C is shunted into a battery or not, and C the output to the battery. The fallacy of the contention is now apparent. How can the steam consumed for the output A + B be reduced by adding the output C to the plant? If by increasing the load of an engine we can reduce the total steam consumption, the reduction would be made if we shunted the part of the output necessary to bring it to full load into resistances, which is, of course, an absurdity.

It is true that the steam consumed for the electricity supplied for charging the cells is very low, perhaps not more than 14lb. or 15lb. per unit, but it cannot be obtained for nothing, or for less than nothing! There is no doubt that some saving might be made by a better manipulation of the plant on account of the confidence which a knowledge of a reserve must give to the engineer in charge. But this will not amount to much, and it is not claimed that the saving is made in this way. What, then, is the cause of the large saving being shown between the two diagrams? It would seem to be this: Fig. 1 is a diagram taken from actual practice, while Fig. 2 is an ideal diagram, where everything is done in the way it ought to be done. If we make an ideal diagram for this load curve without the use of accumulators, we shall find that we can effect nearly as great a saving. The difference will not pay the standing charges to which a battery of accumulators is subject.

Mr. Howell says that a saving of more than 10 per cent. has actually been made by the use of accumulators in this American station, and it is not a matter of surprise that such a

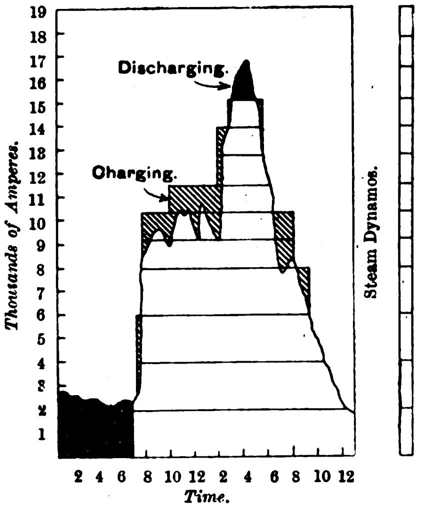

Fig. 2.—With Accumulators.

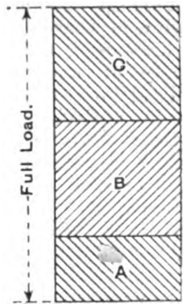

C Battery. **B** Circuits. **A** Standing Losses.

Fig. 3.—Diagram of Steam Consumption.

saving should have been realised; but the accumulators were not necessary for this saving. Mr. Howell says that the steam dynamos were run as near to full load as was considered safe in American practice. But the plants should be run not only at full load, but well above full load. A steam dynamo which will not stand running 20 per cent. above full load (that is load of maximum economy) is not fit for an electricity supply station. Had the units of plant been run in this way in the American station, the intermittent fluctuation in load, and the fluctuation which has a relation to the hour of the day, might have been dealt with with a variation of load factor of steam dynamos which would not have the steam consumption for the day more than about 3 per cent.

In a generating station the units should be so designed that their mean load factors represent the load of maximum economy, generally called full load, and if this is done in a station having a large output and large minimum load, accumulators will be of no economical service.

There are undoubtedly many generating stations where accumulators can effect economy—their advantages as a reserve and as a means of allowing of shutting down the steam plant are of course well known and appreciated by everyone; but it is very important that their function should be clearly understood, and if economy is to be effected by their use upon the coal cost of the generation of electricity which does not pass through the battery it will be of great advantage if Mr. Howell or Mr. Crompton will further explain.

USES OF ACCUMULATORS.*

BY J. C. HOWELL.

After a few introductory remarks with reference to the history of accumulators, the author went on to say that the first uses to which accumulators were practically put was for maintaining continuity of supply in country house electric lighting work. Although the capital cost of the early accumulators was exceedingly high, it was speedily found that the annual saving effected by their use was sufficiently large to recompense the purchaser for his outlay, except in cases where water power was available. In gas-engine work, and with steam engines, the accumulators were found to be working at their best efficiency at a time when, had the motorial plant been in operation, it would have been working at its worst efficiency, and instances are recorded where, by the adoption of accumulators, the gas bill had been reduced to 50 per cent. of what it was when the supply of electricity for household service was obtained from the dynamo driven directly by the engine, and this difference in a case where the former supply had not been in constant service.

The construction of the first accumulators was defective, and for a while accumulators became discredited, owing to the frequent breakdown of the plates of which they were composed, and the falling away of the active material. By slow degrees these faults in construction were discovered and remedied. Then a more abstruse series of faults developed, viz., those due to the chemical actions which were going on in the cell, and which required time to show themselves. These, too, in turn were carefully investigated. During this period the electric light had become so popularised that central stations were established for the supply of electricity. Had the public been content to maintain their demand for lighting at a normal rate whenever they required it, it would have been easy for the central stations to supply electricity in an economical manner. Although it had struck many long-sighted engineers that the public supply of electricity would have to be dealt with finally in much the same fashion as the public supply of water or gas had been dealt with, no one had realised how greatly the demand for lighting at different times of the day varied, and the ordinary engineer greeted the publication of the first load curve of a central station that was published with a smile of wondering bewilderment. In time it became more and more evident that, unless some satisfactory means of providing for this inequality of demand was discovered, electric lighting would for ever remain a luxury.

After reference to the Colchester installation the author remarks that this scheme had shown that accumulators, to be of real service in central station work, had to be capable of meeting for short periods demands considerably in excess of their normal capacity. This fact being properly appreciated speedily led to the development of accumulators, which could, on being called upon, discharge at very rapid rates, and, although these accumulators were costly, it was discovered that their freedom from breakdown in trying circumstances was such as to warrant a trial being made on a sufficiently large scale to see whether this new form would be fully equal to all the requirements of central station practice. Reliable statistics, too, were at this time available, so that engineers could fully realise the costs of working under the peculiar conditions which the public demanded, and it was found that the cost of fuel was from four to six times what had been expected from the results obtained when working an engine and dynamo under test. To make this matter clearer the author exhibited a Table (I.) and curves of the efficiency of a steam-driven dynamo at various loads.

Table I.—*Non-Condensing Willans Set.*

Engine load factor. Per cent.	Lb. of coal per unit.	Cost of coal per unit. Coal at 20s. per ton.
20	7·3	0·78d.
30	5·4	0·57d.
40	4·75	0·5d.
50	4·3	0·46d.
60	4·0	0·43d.
70	3·75	0·4d.
80	3·5	0·37d.
90	3·4	0·36d.
100	3·3	0·35d.

Similar engines, when dealing with the business of supply, had, the author said, been tested by Prof. Kennedy at actual work. These results the author has embodied and amplified in Table II.

Taking as an example of the use of Table I. that there is 100 unit, steam dynamo running at maximum efficiency, the author

Table II.—*Kennedy Table of Consumption on Variable Loads.*

—	11 a.m. to 6 p.m.	6 p.m. to midnight.	Midnight to 11 a.m.	Whole day.
Time	7hrs	6hrs.	11hrs.	24hrs.
Total I.H.P. hours	562	1,366	407	2,335
Total E.H.P. hours	400	979	260	1,639
Units generated	293	731	193	1,217
Coal consumed	3,838lb.	4,459	2,547	10,844
Coal per unit	13·1lb.	6·1	13·2	7·33
Coal at 20s. per ton	1·4d.	0·65d.	1·41d.	0·8d.

points out that it will need under the most perfect conditions of running 3·3lb. of coal per unit, or 330lb. per hour. Increase the load 20 per cent. and another similar set has to be started, so that the load is divided between them; each set is now working at 60 per cent. load factor, the amount of coal consumed is 4lb. per unit, or 480lb. Thus an increase of 20 per cent. in the load involves an increase of 45 per cent. in the coal consumption, and the actual loss owing to the decrease in efficiency is 9½d. per hour in the coal bill alone as long as the 20 per cent. extra load is maintained. That these losses are real, and are actually found to exist in practice, is at once discovered by reference to the Kennedy table, where we find that there was less coal burned during the period of heavy load than during the period of lighter load—that, in fact, 63 per cent. of the total amount of fuel consumed was used to provide 33 per cent. of the output. The day on which these tests were taken was divided into three parts closely corresponding with the times as shown on a load curve where there is a minimum demand, a moderate demand, and a maximum demand. It will be noticed that the amount of coal required for the moderate demand approaches very closely to the total amount required for the maximum demand, and that during the period of minimum demand, when only some 20 per cent. of the maximum output was delivered, the coal bill reached the respectable figure of 57 per cent. Further, it will be seen that during the period of lighter load an amount of coal was consumed sufficient, working at the rate shown during the period of maximum demand, to produce 1,050 units, or very nearly the *total daily output required*. Had some suitable means of storage been provided, enabling the engine to run at a fair rate of economy, there was a possible chance on that day's output of effecting a saving of two tons of coal during the run.

As an example of the sort of problem with which the central station engineer has to deal the author then gave some particulars with reference to an American station. The plant was capable of dealing with a maximum output of some 18,800 amperes made up in four sets of 2,000 amperes each, and nine sets of 1,200 amperes. From the marginal scale at the side it will be noted that at no time during the day did the station touch an engine load factor of 80 per cent. except for a few minutes at the peak of the diagram.* Starting at one o'clock in the morning set No. 15 was kept running nearly the whole 24 hours; set No. 11 ran from one o'clock till half-past nine, and, if the level that No. 11 set combined with No. 15 would have taken be carefully noted, it will be observed that during the whole period of minimum demand the engine load factor did not reach even 60 per cent. as an average. At seven o'clock, when the load commenced to rise, the additional load had to be dealt with by adding small set after small set, and it was only when the load was rising so rapidly near the peak were they able to fully utilise the larger sets, which ought *à priori* to be more economical to run than the smaller sets. The same criticism will apply on the down grade when the demand is decreasing. The coal consumption at this station on the day on which the curve was taken was 80 tons. On further reference to this curve, it will be seen that the two larger engine sets were kept going at as near their maximum output as in American practice is considered safe, taking the sudden abnormal changes of load into account, and that the balance of the load was equally divided over all the other sets that were at the time running. The result of this complicated system is that although by the number of engines running the efficiency of each is somewhat increased, the regulation of the pressure on the mains is more difficult, as the adjustment to standard is only really effected when the current from the last machine is properly adjusted. That the labour involved in this adjustment is considerable is easily understood on reference to the diagram.

The author then stated that there were now methods very fully described by which the use of accumulators would relieve the central-station engineer from all anxiety as to his variable demand. He had prepared a chart showing how the methods described would deal with the load curve which he had put before the meeting. The first thing to ascertain is the output for the period of minimum demand, and for what time the minimum demand lasts. These

* Abstract of a Paper read before the Northern Society of Electrical Engineers.

* [Reference should be made to the diagrams illustrating Mr. Cowan's article, p. 223.—Ed. *E.*]

Digitized by Google

figures enable the capacity of the accumulators required to be ascertained. This period of minimum demand is very clearly defined on the load curve in question as lying between 1 a.m. and 7 a.m., a period of six hours. During this time an average of 2,100 amperes have been delivered to the circuit, or, in round figures, a total of 13,000 ampere-hours. To provide for this output and allow a margin for contingencies, a set of accumulators having a capacity of 14,000 ampere hours will be required. An inquiry addressed to modern accumulator manufacturers brought the information that such a battery would cost, delivered and erected, £7,000.

On adding this battery to the equipment of the station the result upon the working of the motorial part of the machinery is that whenever an engine is started it can be kept at full load from the moment it starts to the moment it ceases running, thus bringing up the efficiency of the station to 100 per cent. engine load factor at once. The result may be observed on the load diagram. Instead of the patchwork jumble of in and out engine loads, each set is working steadily at full output as long as it is required; the hours of running have been shortened from 24 to 18, thereby lessening the number of men employed. More than this, it has been possible to commence running with three of the large sets at full load from the moment of starting up to 7 a.m., and that these engines run steadily throughout the day. It is also to be noticed that when the load increases the accumulators, although discharging during the early morning hours, have already received sufficient charge to permit a discharge until three more engine sets can be started simultaneously, pointing out the advisableness of employing fewer sets of larger plant for this station. The only regulation required is the steam pressure at the boilers, which must be kept constant, and a slight increase in the speed of the engines as the load creeps up to compensate for the slight additional loss in potential in the feeders leading the current away from the station.

The author thinks that he will very probably be told that, owing to the variation in the E.M.F. of the battery during charge, the regulation of the charging current will be an exceedingly difficult matter. This can be dealt with by making one of the steam dynamo sets expressly to give just the current necessary for properly charging the battery, and no more. It is the first to be started up, and it is the last to leave off, and is, during the whole day, prepared to charge the battery except at the time when the output called for is in excess of the current generated by all the sets in combination. It is kept permanently attached to the regulating ends of the battery. An adjustable switch is so arranged that the terminals of the machine can be attached to any cell in the regulators, so that as the end cells get charged up the switch may be moved down until it reaches the cell, which is in connection on the discharge side with the terminals of the other sets and with the circuit. The loss in charging the accumulators is very slight, as it is only felt by one unit of the plant, and is really in the load diagram in question only 1 per cent. of the total load delivered to circuit, as the proportion between the load dealt with by the accumulators and the total output is just slightly over 8 per cent.

Even the most casual glance will show how immensely simplified the station work has become, a certain number of engines running, a certain amount of steam required, the engineer in charge directing everything with quiet confidence, knowing full well that he has a big reserve always behind him capable of dealing with an extraordinary demand, or with any little accidental occurrence. Further, a comparison made between the two curves will at once show that the labour bill will be considerably reduced by the employment of accumulators, the amount of the saving being worked out by the author for the case in question at £1. 15s. 6d. a day. The coal bill will also shrink as engines have ceased running during the period when using coal most wastefully, and moreover engines are able to run at full load whenever they are running. Working out the amount of coal required for each engine, the author brings down the amount from 80 tons to 67. The total saving is worked out at £15. To effect this saving there has been an outlay of £7,000 in a class of plant which, the author remarks, in the minds of most engineers should submit to a heavy charge for depreciation. The author then sets aside a sum sufficient to meet the views of these engineers by putting on the other side of the account an amount of £2 per day for depreciation and £1 per day for interest on the outlay. The net saving, therefore, is reduced to £12 per day, or, say, £4,380 per annum, an amount sufficient to wipe off the whole capital cost of the accumulators in two years, and still leave a margin to go to the profit and loss account.

The author, after suggesting the use of accumulators in factory and mining and electric tramway installations, asserts that wherever there exists an intermittent demand for a supply of electricity an electrical storage system is a necessity, unless the cost of the initial power is so abnormally low that the interest charges on the accumulator outlay amount to more than the annual saving to be effected. Such causes do sometimes occur when an abundant supply of water is available close at hand.

DISCUSSION.

Mr. WORDINGHAM said Mr. Howell's Paper bristled with what he (Mr. Wordingham) believed to be facts. He thought, looking at it broadly, that it would be very difficult to assail Mr. Howell's position. To his mind there was no doubt that storage to a certain extent was essential to the economical working of a station. In Manchester they had put down a very large battery of 400 H.P. for 2½ hours' supply; this they had put within a mile of the station for the double purpose of effecting the economy Mr. Howell had spoken of, and to save putting down more conductors. He hoped they would introduce considerable economy by the use of this battery. One thing always occurred in dealing with these secondary batteries: they were so useful for a light load, and so useful at full load, that the difficulty was to know when to charge them.

Mr. RIDER said that, while he thoroughly agreed with Mr. Howell on most of the points raised so far as they concerned the generating station, he could hardly at that stage enter into the reasons why a high-tension system could still be of service. Unlike most men who put down high-tension stations, he had such faith in accumulators that he put them down wherever he could find a use for them, such as for exciting the alternators. His experience of cells was that the Crompton-Howell cells were very good; they had the fault, however, which, he thought, all cells had, that although one could take a very high discharge from them for a short time, they could not be charged at a high rate: that, he thought, was a point which some makers would do well to look at in the future. If the cells were discharged at a high rate, they wanted to be charged at a high rate.

Mr. CLIREHUGH said Mr. Howell had alarmed them very much by using the Kennedy table of coal consumption, but he did not think he (Mr. Howell) meant it to represent the actual working of a central station; they would see, by referring to the two tables, that when he had consumed 13·2lb. of coal per unit he had reduced his engine to 20 per cent. therefore the difference of 13lb. of coal, as against the 6lb., would, he thought, never be sustained in practice.

Mr. FAWCUS said it had given him great pleasure to listen to Mr. Howell's most able Paper, although personally he could not agree with much that he had said. The saving of £13 a day in coal looked very nice on paper, but he was disposed to doubt its accuracy. It was almost impossible for any one of them to-night who had merely listened to the Paper without having any opportunity of studying the figures, to discuss the matter properly; if they had time for reflection perhaps some of them would be able to put Mr. Howell right. Mr. Howell might have given them some little information as to the actual results in pounds of coal consumed per unit in the most modern battery stations. If such a large saving could be effected by the use of accumulators, why was it they saw an alternate-current high-tension station beating the figures of all continuous-current stations?

MONDAY, MAY 27TH.

Mr. COWAN said that at the last meeting he felt anxious to check Mr. Howell's claim of a saving of £13 per day in coal by using accumulators in the American station, of which diagrams were before them. Since then he had gone carefully into the matter, and could not see that such a saving or anything like it was possible with so small a battery. The only way in which economy could be realised by the use of a battery was by storing electrical energy when it cost little to generate, and taking it out for the circuits when its generation first hand would be expensive. It therefore followed that the only saving which could be effected must be made upon the electrical energy which passed through the battery. How was a saving of £13 per day to be made by the use of a battery which only dealt with £5 or £6 worth of electricity, taking its fuel cost at 1d. per unit? He thought that under the conditions of load at the American station 1d. per unit for coal was an ample allowance. It might be claimed that a saving would be effected on the whole output of the station, as the load factor of the engines was raised to 100 per cent.; but a little consideration would show that this was a fallacy. The only further saving which could be made would be due to the better management of the plant on account of the reserve allowing of its better manipulation; but this was a small matter. It seemed to him that Mr. Howell obtained his result by comparing an actual diagram taken from practice with an ideal diagram where everything was done in a perfect way. If they looked carefully at the actual load diagram they would see that it was peculiar in many respects. The "in and out running" of the engine load line suggested that the man who was jockeying that plant had heavily backed accumulators. Mr. Howell said that the engines were run as nearly at full load as was considered safe in American practice, but they ought to be run not only at full load but above full load. A steam dynamo which could not be run, at any rate for limited periods, 10 to 20 per cent. in excess of its full load (that is, load of maximum economy), was not fit for an electricity supply station. If, instead of spending £7,000 on a battery, they engaged the services of an engineer who understood better the principles of the economical management of an electricity supply station, they might effect an equal saving without the heavy charge to which a battery was subject.

Mr. RIDER said he believed that cells were a good thing to have in a station, for the reasons Mr. Howell had stated in his Paper, for bringing up the engine load factor to 100 per cent., and because the shifts could be reduced at a certain part of the day. He did not see that there was very much in the use of accumulators as a stand-by against breakdowns, because if the station was properly arranged he would as soon have a good engine and alternator to fall back upon as a set of cells. Cells could be as readily used in an alternating-current station as in a direct-current station. Let the day-load alternator be fitted with a rectifier, and let them transform down to 150 volts or so such power as was not being used for the circuits. Let them send this transformed current through the rectifier, and charge a set of cells. The engine load factor could thus be brought to

Digitized by Google

100 per cent. throughout the day, and the cells could be used to run a motor alternator whenever desired, and particularly after midnight and on Sundays. The whole steam plant could be shut down on those occasions. Although accumulators would enable to do many good things, they would have to be very much improved before they would be highly satisfactory, because, as he remarked at the last meeting, cells could not be charged at a high rate, but it would take from eight to ten hours to fill them again. That was one of the points he thought the makers would have to alter before the cells would be of any great service.

Mr. CROMPTON said he was sorry to say that in the old Institution, which he had the honour to represent, they had far too many cases of a meeting consisting either of a number of students or teachers, who had not yet had any practical experience of the business, or men who had all their own logs to roll. They sometimes got meetings that were not as practical as he would wish. He had read the discussions of the Northern Society, and they had appeared to him to be very much the sort of thing that he had often wished had been the case in his Institution. He had read Mr. Howell's Paper, and he thoroughly agreed with him in the remark he made on the subject that the men above all others whom they wished to hear speak were the men in charge of the stations. It had been said that he was what was called a low-tension man; he was not a low-tension man at all, but he was most strongly an anti-alternator current man. Alternating currents were no doubt a splendid thing in their way to professors and schoolboys, but nasty things to deal with in central stations. One of the principal reasons why they were so nasty to deal with was that they did not allow accumulators to be easily used. Mr. Howell had converted him to the use of accumulators, and the way he did it was to show him (Mr. Crompton) that he would be able to work without that anxiety and worry which attended all central-station work. It was perfectly true that accumulators did waste a certain amount of energy, but it was certainly not more than 15 per cent., and in some cases less. There was such a large saving by the better loading of the engines, and that was where the big saving took place. The difference between having engines loaded to about 50 per cent. and to about 90 per cent. was very large indeed. He had got an alternating station of his own at Chelmsford, and he had tried for two or three years to scheme in a few things to increase their income; one was the use of motors. He would only say that if any man would show him how he could drive four or five printing offices with motors without interfering with the lighting, he would make that gentleman a present of £50 to-morrow, and if they could show him how to use accumulators so that he could make money by them between his generating plant and his network, instead of between his network and the consumers, he would also be glad to hand over another cheque for £50.

Mr. HESKETH said he had heard it claimed by advocates of batteries that the ideal use of electricity was that given to gas—that was to say, to store it up to be used just as it was wanted. He was aware that the argument was very far fetched, and that it never was intended to accumulate all the supply, as in gas works; but an analogy taken from this view might be instructive. Suppose they had an accumulator with a capacity of 14,000 ampere hours, it would cost £7,000—that was to say, assuming 3½ watts per candle, they had for £7,000 a storage equal to 400,000-c.p. hours. For the same number of candle-power hours a gas-holder cost £1,500. There was rather a wide difference between those two figures, and if they were to adopt very extensively any system of storage they must have something cheaper than the present accumulators. He would like, if it was not asking too much, to have some typical cases given where the cost of coal could be given for the units that were taken out of the battery. As to the point mentioned by Mr. Cowan of overloading plant, he would not like to be in charge of a station where they could not overload at least 20 per cent., because if the plant broke down they must be able to overload at least to that extent.

Mr. FAWCUS said that, after the very strong condemnation of the use of the alternate current by Mr. Crompton, he felt some reply ought to be made. Although he was not a rabid supporter of any particular system, he desired to see the two fairly compared. He had taken out roughly the results obtained by the six commercially best low-tension stations and the six commercially best high-tension stations, and the low-tension had so far the advantage in cost of production. It so happened that three of each kind were managed by Corporations, and three by Companies. The six low-tension were Burnley, Brighton, St. James, Westminster, and Liverpool, and the six high-tension stations Newcastle, Newcastle and district, Hanley, Leeds, Huddersfield and Portsmouth. The cost of production in the low-tension stations was 1·78d. per unit, and in the high-tension stations 1·93d., being a saving in favour of low-tension stations of 7 per cent. in cost of production only; but that cost of production only meant about half the total cost of the current, so that the saving fell down to 3½ per cent. on the total cost. Again, the low-tension stations paid £120 per kilowatt for their plant, while the high-tension stations paid £80; that was to say, the low-tension stations, to obtain the saving, paid 50 per cent. more for their plant than the high-tension; also this comparison was very favourable towards the low-tension stations for another reason: the average time of running was four years, while the average time the high-tension stations had been run was two years. Again, the districts that were being served in the case of the low-tension were all congested districts, whilst in the other cases the districts were very much more spread about. He had remarked upon the peculiarity of the peak of the diagram shown of the American station, and suggested to Mr. Howell that as the heaviest load came on at four o'clock in an afternoon in June, the station was probably in the neighbourhood of the South Pole, or the diagram was taken during an eclipse. Mr. Howell had, however, assured him this peculiarity was caused by motors running in at four in the afternoon. At all events, it was a pity that a more reasonable diagram had not been chosen instead of one which appeared to show the station running under almost impossible conditions.

Mr. MOUNTAIN said he did not think the saving would be anything like that described. He thought Mr. Crompton did not apparently appreciate the position of electric supply undertakings in provincial towns. The fact mentioned by Mr. Fawcus was of great importance in considering the relative values of each method of supply. The area of supply must come very largely into the question. Taking Huddersfield as an example, some houses taking a supply of electrical energy were as much as 3¾ miles from the supply station, and these houses were actually the best consumers, taking more energy than the largest buildings in the central portion of the town, owing to the fact that they were burning their lights nearly all the night through, and he could not see how a provincial town was to be thoroughly covered with a network of low-tension mains owing to the enormous amount of money required, although for congested districts they might do very well indeed.

Mr. HENRY EDMUNDS (President) said he thought Mr. Howell had given them a very good and interesting Paper. Mr. Mordey had once said to him that the beauty of an alternating current was that it would not charge an accumulator. He asked him if he were still of that opinion on seeing him one day after reading the Paper. Mr. Mordey's reply was, "Show me a good accumulator—a really good one—and probably I shall alter my opinion." It was a good accumulator that was wanted.

Mr. HOWELL, in reply, said Mr. Cowan had unfortunately fallen into serious error in considering that the saving in coal would only be effected on the number of units stored by the accumulators. On the contrary, *the saving was made on every unit generated*, since the efficiency of the station as a whole was raised. As a corroboration of the saving of the 13 tons mentioned in the Paper, it was only necessary to refer to the Kennedy table, where the pounds of coal per unit for the day's output was 7·33, and for the period of maximum load, when the engines would be running at higher efficiency 6·1, or almost the exact ratio given for the station mentioned in the Paper, 80 tons without accumulators, 67 with. Mr. Cowan would thus see that his apparent generosity in *giving* the coal required to charge the battery was entirely misplaced, and, paradoxical as it might seem to him, the station required less coal for a greater number of units generated when fitted with accumulators than it would need for a small number of units generated without accumulators. With regard to Mr. Rider's remarks on accumulators and their use in alternating-current stations, there could be no question that the engineer in charge was considerably relieved by having in his exciting circuit a reserve such as an accumulator would give, and extension would probably take place in the way that Mr. Rider had suggested. Mr. Hesketh's demand for figures as to efficiency was somewhat amusing. What need of inquiring too closely into the efficiency of the battery when, inefficient as it was, it effected a saving in a station using 80 tons of coal of £4,300 a year. Mr. Hesketh, however, might take it that the energy efficiency over 12 months' running would not be less than 85·6 if the batteries were properly worked, and this figure had been attained in actual practice at one of the Westminster stations under Prof. Kennedy's charge. Accumulators were frequently overcharged, and it was not the fault of the accumulator manufacturers that the efficiencies obtained were frequently so low. Mr. Fawcus had brought an interesting list of stations. Portsmouth, which was one of the stations named, did not give a constant service; hence its figures were of no earthly value at all. Any station could generate current at period of maximum load and pay. It was the period of minimum load that made electric lighting in some cases difficult from a commercial standpoint, and it was this period of minimum load that accumulators took care of.

THE BRUSH CONSTANT POTENTIAL ARC LAMP.*

The growing demand for a reliable constant potential arc lamp for use on incandescent circuits has led the Brush Electric Com-

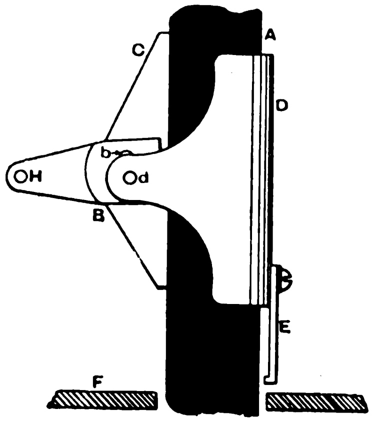

Fig. 1.

pany, of Cleveland, to design a lamp which will prove satisfactory under the various severe conditions to which such lamps are subject. This lamp, shown in the accompanying illustrations, is claimed to be without any of the objectionable features found in lamps of the

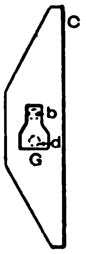

Fig. 3.

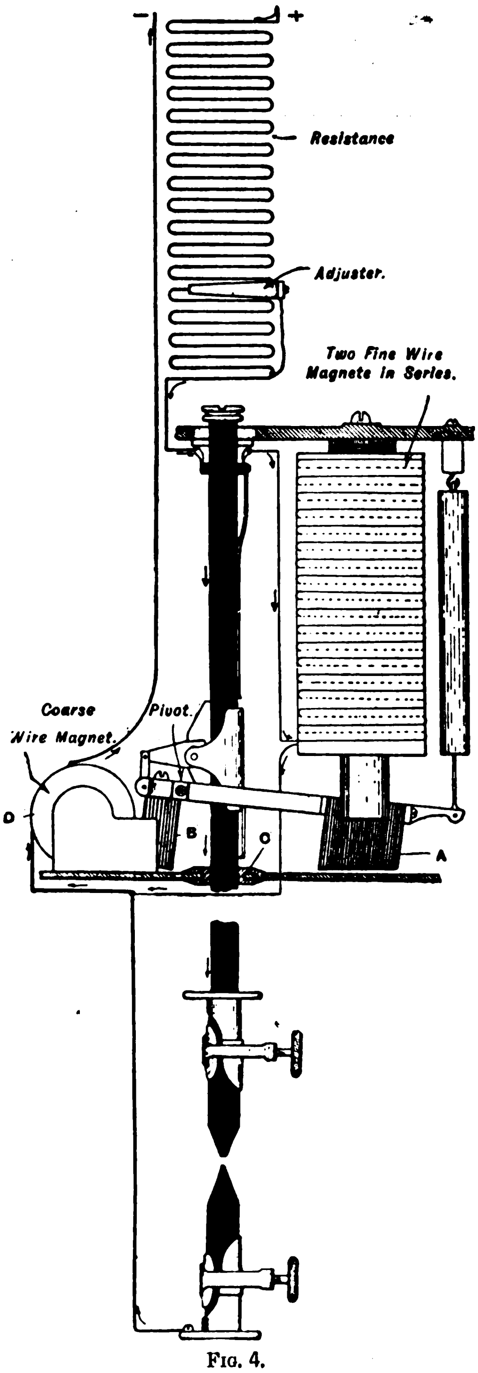

Fig. 4.

of the moving parts, the friction is diminished, and the weight greatly reduced.

Among the desirable features of the regular Brush constant current lamp that have been adapted to the new constant potential lamp, is the clutch, Figs. 1, 2, and 3, the result of 15 years of experiment and experience. In this clutch the lever B is supported at H by an armature lever. Fig. 1 shows the clutch gripping the rod, and as the armature moves up and down it will carry the rod also. However, in descending, the clutch will only grip the rod until the trip E touches the plate F, when any further fall of H will release the rod by pulling C back as in Fig. 2. The raising of the armature lever at H immediately closes the clutch and lifts the rod with the lever. This clutch presents such a long gripping surface that a dent or enlargement in the lamp rod will not affect its operation in the least. The opening G (Fig. 3) is of such form as to prevent clogging by dirt or dust, and never requires cleaning or repairing. The position of the rivets through the opening G is shown at *b* and *d*.

Fig. 4 is a diagram of the lamp, showing the carbons separated, as when the lamp is not burning. When the current is switched on its only path is through the fine-wire magnets, which at once draw up the armature A, slowly lowering the clutch and rod until the carbon points come in contact. If the trimming of the lamp is regular, the carbon points will touch before the clutch releases the rod, consequently the carbons cannot lap (a common trouble with constant potential lamps), for the instant the points touch, a path for the current is closed through the coarse-wire magnet D which attracts the armature B, overcomes the pull of the fine-wire magnets and lifts the clutch which again separates the carbons and establishes the arc. The pull of the fine-wire magnets is constant and the strength of the coarse-wire magnet varies with the resistance of the arc as they are in series. As the carbons burn away the resistance of the arc increases, and consequently the current flowing through the coarse-wire magnet decreases until the fine-wire magnets overcome its pull and slowly lower the carbon rod, thus maintaining a constant arc until the clutch trip reaches the plate C and releases the clutch. This allows the carbon rod to slide downward a little, but it is instantly caught and raised by the clutch as the carbon points come nearer and allow increasing current to pass through the coarse-wire magnet. When the carbons have been consumed, the circuit is opened at the arc of the first pair of carbons that can feed no more, and the carbons in the other lamp that are not yet consumed continue to touch and spark slightly, thus indicating that it is the dark lamp which needs trimming.

The lamp is simple both in design and construction and pleasing in appearance.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, June 14th,

Physical Society.

5 p.m. Meeting at Burlington House. The following Papers will be read: (1) "The Measurement of Cyclically Varying Temperatures," by H. F. Burstall; (2) "The Thermal Constants of the Elements," by W. F. Deerr; (3) "An Electromagnetic Effect," by F. W. Bowden.

WEDNESDAY, June 19th,

Royal Meteorological Society.

7:30 p.m. Ordinary Meeting at the Surveyors' Institution, 12, Great George-street, Westminster.

Society of Arts.

9 p.m. Annual conversazione at the South Kensington Museum.

A New Use for Accumulator Grids.—The return of the hot weather reminds us of an instance of the novel use to which an ingenious mind can put a secondary battery plate. Not a hundred miles from Farringdon-street there was to be seen last summer the grid of a secondary-battery plate of well-known type. As in ordinary practice, it lay in a glass cell; it also had an acid electrolyte, but the vessel was a cylindrical bowl and the electrolyte dilute "lemon squash." The use to which the grid was put was to keep in position the metal syphons used, a few of the meshes of the grid being cut away to admit the end of the syphon, and the corners of the grid were turned down, to keep it well clear of the bottom. It would be interesting to know how the owner of the business came into possession of the plate; also the effect of the liquid (which had to pass through the meshes of the grid) upon the internal economies of its consumers.

The Electrician.

(The Oldest Electrical Journal, 1861—1878.)

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny
Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	YEAR.	HALF-YEAR.	QUARTER.
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to* **4** *p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is in preparation.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.

VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.

VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. 93 original illustrations, handsomely bound, price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A EWING, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

THE WORK OF HERTZ. By Dr. O. J. LODGE. Price 2s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c. By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

SPECIAL NOTICE.

Owing to the growth of the electrical and allied industries the demands for space in "THE ELECTRICIAN" are, for the greater part of the year, so pressing that a permanent increase in the size of the journal has become necessary. To meet the increased cost involved by this step, and by other improvements, such as heavier paper and more numerous illustrations, the price of "THE ELECTRICIAN" has from May 3rd been advanced to 6d.

The Subscription to "THE ELECTRICIAN," commencing with Vol. XXXV. (May 3, 1895), is as follows:—

	YEAR.	HALF-YEAR.	QUARTER.
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

NOW READY.—Vol. XXXIV. of "THE ELECTRICIAN," bound in strong cloth. Price 12s. 6d., post free 13s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

ABSOLUTE RESISTANCE.

Few circumstances bring the scientist more completely face to face with the mutability of earthly, and indeed of all material things, than the attempt to rationalise any complex physical unit, such as that of electrical resistance, by expressing it in absolute measure. Interchange of exact thought in modern times calls into existence the need for a system of units; and it is desirable, if the researches of one man are to be intelligible to his fellows in all places and at all future times, that not only shall all men work with one universal system of units, but also that any one of those units shall be capable of reconstruction from an exact and unvarying specification. Thus arises the necessity for a standard of each particular unit; and it will be seen that, with a view to the selection of any standard, only two courses are, practically speaking, possible: either the standard unit may be arbitrarily fixed and crystallised, as it were, in a manufactured material apparatus, or it may be defined in terms of such physical properties of the universe as are least liable to change with time and throughout space. The latter has been named the absolute or rational method; because, on the hypothesis that it is a workable process, it would arrive at a unit which would be free from the changes and decay of ordinary material apparatus and things. The former method cannot in this sense be termed rational, and to make this clear let us fix our thoughts upon one particular unit—that of electrical resistance.

Digitized by Google

By an Order in Council, dated August 23, 1894, the Queen approved of "a standard of electrical resistance denominated one ohm, being the resistance between the copper terminals of the instrument marked 'Board of Trade Ohm Standard Verified 1894' to the passage of an unvarying electrical current when the coil of insulated wire forming part of the aforesaid instrument and connected to the aforesaid terminals is in all parts at a temperature of 15·4°C." And the limit of accuracy of such a standard resistance is specified as being required to be "within one-hundredth part of 1 per cent." Although, therefore, a polite reference is made in the Order in Council in question to its scientific pedigree, the legal ohm is actually a material apparatus, and as such it is liable to suffer those changes which Time seems inevitably to effect in all material things, only one of these changes, namely, that of temperature, is guarded against in the specification. But, as was so clearly pointed out by Prof. VIRIAMU JONES recently, in his masterly lecture at the Royal Institution, there are other influences which are liable to arise which may vary the standard within the specified limits of accuracy. The state of aggregation of the material particles composing the standard resistance, and the condition of internal stress and strain among those particles, cannot either be guaranteed to be constant, nor can their variation be guarded against, as in the case of temperature, because it is not possible to determine the magnitude of their changes. Yet these exert considerable influences on the magnitude of the resistance. It was considerations such as these which led Prof. JONES, in his lecture on "The Absolute Measurement of Electrical Resistance," to which we have already referred, to advocate the "rational" method of fixing a standard of resistance, and to press the plea that the time is now ripe for its "frank and full acceptance" by the Government, though since the Government is now definitely committed to the metallic standard ohm, one would have thought that the time was, perhaps, over-ripe. The merits of this alternative and, by assumption, absolute method are based upon the fact that it depends upon only the most permanent phenomena of the universe—that, in fact, it defines the standard in terms of rational mathematical magnitudes, and banishes all the irrational quantities to the ether, "to which," as Prof. JONES quaintly observed, "they properly belong," and in which, at any rate, they will have the merit of being constant, even though they are not measurable. A unit which is constructed or defined only in terms of the joint properties of Space, Time, and the ether, and which has had eliminated from it every specific property of mutable matter, may fairly be termed rational and may be considered as close an approximation to the absolute as is attainable by the efforts of mere mortals. It is such a unit of electrical resistance as this that Prof. JONES advocated in his lecture—a unit depending only on the centimetre, the second and one specific property of the ether; in other words, the C.G.S. electromagnetic unit of resistance.

This little C.G.S. unit is no stranger to electricians; they have long recognised his existence in the abstract, and have even labelled their standard ohms as being equal to a certain number of millions of him. But it is one thing to know of the existence of a C.G.S. unit in the abstract—to be able, so to speak, to chalk it up on a blackboard—and it is quite another thing to materialise that unit in solid copper, within the degree of accuracy required by the specification of the legal ohm, viz., within an error of one part in 10,000. This is the crux of the whole matter. Can the reproduction of a given number of these absolute units, say 10^9, of them in a length of copper wire be guaranteed with the degree of accuracy required by law? Prof. JONES thinks he can undertake the task, and has given his grounds for so thinking. The geometrical and other physical dimensions of the apparatus which he has devised for the purpose of this absolute method, a model of which he exhibited in action at the Royal Institution, are capable, he assures us, of measurement considerably within an error of one part in 10,000. The quantities thus to be measured are: the configuration of a coil of copper wire carrying a current for producing the inducing field and the speed of rotation of the inductor disc in which the induced electromotive force—which is to balance the potential difference at the ends of the measured resistance—occurs. There should be no difficulty in ascertaining, to the required degree of accuracy, the dimensions of a cylindrical coil of the size and careful construction used, and Prof. JONES has abundantly proved that fluctuations of speed within this degree of error may equally easily be detected and compensated, while the actual speed itself is simultaneously determined to an equal approximation. The Imperial ohm, therefore, gains nothing in accuracy by being specified in terms of an actual piece of copper wire; while it runs the inevitable risk of suffering indeterminate changes in the magnitude of its real electrical resistance. And the Government possesses no means whatever of ascertaining from time to time whether such a change has or has not taken place. Let but a suspicion of inconstancy in this standard bit of wire arise in the official mind, what other safeguard can officialdom have than to compare its bit of copper with some other bit of copper, which may just as likely have undergone the elusive change? It has none whatever — unless, indeed, it elects to hand its standard over to Prof. JONES, and asks him to determine how many millions of his constant little absolute units it is equal to. And to do that would be to make the rational system of standardisation the final court of appeal—a course which, sooner or later, will have to be frankly adopted.

We cannot conclude our remarks on this subject, so intimately connected with the painstaking researches of Prof. VIRIAMU JONES, without paying a tribute to the lucid style and scholarly diction with which its intricacies were explained to his audience, largely non-technical, at the Royal Institution. It was a bold essay to attempt to interest and instruct such an audience in matters connected with coefficients of mutual induction, mathematical equations, and the like. But if those of his audience whose interests lay outside of technical matters were unable to derive much scientific instruction from lecture, we are sure that even to them the hearing of such a scholarly discourse must have been a literary treat; while to many present Prof. JONES' lucid style must have invested dry, every-day matters with an unexpected charm.

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(Continued from page 195.)

42. **Battery Resistance.**—The most simple and reliable methods of measuring the internal resistance of a battery are Mance's bridge method and the half deflection method. These are described in the text-books, but it may be desirable to state them briefly here.

The connections for Mance's test are given in Fig. 118. The battery is disconnected from the key, and put on to the line and earth terminals of the bridge. Balance is obtained when

* Copyright. All rights reserved.

Digitized by Google

no change in the galvanometer deflection occurs on opening or closing the test key. The resistance of the battery is then found by the ordinary bridge proportion, as if it was a simple resistance without E.M.F. It is necessary to use a shunt on the galvanometer to bring the deflection conveniently within the scale, and it is sometimes convenient, when the battery is a small one, to add a resistance to it, which is afterwards deducted from the bridge result.

The advantage in this test is that balance is obtained to one deflection. In observing that a given deflection does not alter on pressing a key it is not possible to make any mistake, as the very slightest movement of the spot from the fixed deflection can be detected. It might be called a null method to false zero.

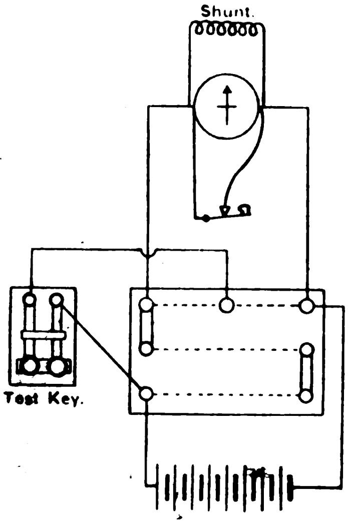

Fig. 118.

The half-deflection method is carried out by the simple connections given in Fig. 119. The galvanometer is shunted with a very low resistance—a few ohms—so that its resistance may be neglected in comparison to that of the battery and adjustable resistance, and a convenient deflection obtained with any resistance unplugged in the box. Note the resistance unplugged, and the deflection. Now unplug more resistance, until the first deflection is halved.

To halve the deflection (or current) the total resistance in circuit must have been doubled, and, therefore, the total resistance unplugged for half deflection must be equal to the battery resistance plus twice the first resistance. Subtracting twice the first unplugged resistance from the total resistance unplugged gives the resistance of the battery.

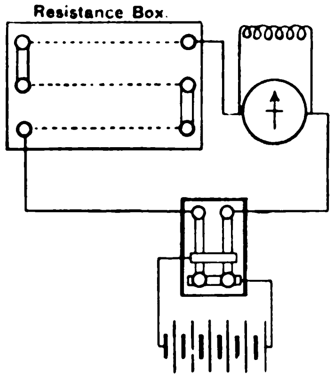

Fig. 119.

43. **Simultaneous Battery Resistance and E.M.F. Test.**—A reliable null method which in two readings would give both the E.M.F. and resistance of a battery appeared to the author to be desirable, and he has devised the following simple form of test.

The battery, whose E.M.F. (E) and resistance (b) we have to find, is connected direct to two resistances, R and r (Fig. 120). A standard cell of e volts is connected through a key and galvanometer across the resistance r, as shown. The smaller resistance (r) is fixed, while the larger resistance (R) is adjusted till there is no deflection on the galvanometer when the key is closed. We have then the distribution of potential shown in Fig. 121.

Now increase the small resistance n times (making it $n\,r$), and alter R till balance is again obtained. Suppose that R is altered to R_1 to effect balance. Then we have the distribution

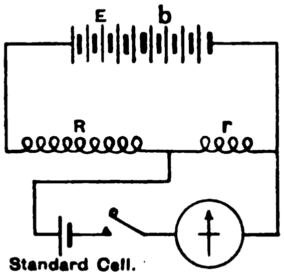

Fig. 120.

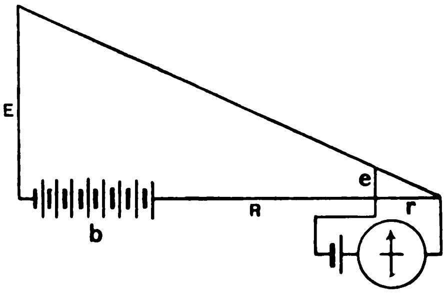

Fig. 121.

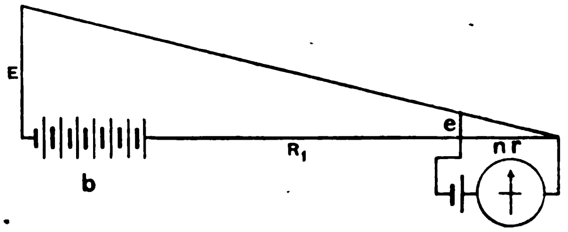

Fig. 122.

of potential shown in Fig. 122, and it is evident that, the current being $\frac{1}{n}$th of its former value and the two E.M.F.'s remaining the same, we have

$$R_1 + b = n\,(R + b),$$

whence the resistance of battery (b) is equal to

$$\frac{R_1 - nR}{n-1} \text{ ohms.}$$

Also it is evident that the E.M.F. of the battery (E) is equal to

$$e\,\frac{R + b + r}{r} \text{ volts,}$$

which can be put in the simpler form of

$$e\left(1 + \frac{R+b}{r}\right) \text{ volts.}$$

Hence, by two simple balances of the galvanometer to zero, we have both the E.M.F. and the resistance of the battery.

The ordinary bridge box can be used very conveniently for this test connected as in Fig. 123. It is convenient to use the two 100 coils in the bridge ratio arms for r, making it 100 for the first balance and 200 for the second (that is $n = 2$). With $r = 100$ we adjust the resistance in the box till there is no deflection on the galvanometer (the resistance so unplugged being R ohms). Then making $r = 200$ we adjust the resistance again to balance (the resistance unplugged being R_1 ohms). Then, since $n = 2$ we have

$$\text{resistance of battery} = R_1 - 2\,R.$$

Digitized by Google

By having $r=100$ at first we ensure that, with a standard cell of a little over a volt, the current from the large battery through the bridge coils does not at any time exceed 14 or 15 milliamperes, which is too small to have any heating effect on the coils. A key is put in the large battery circuit, so that the current need only be on for a few seconds while getting balance.

An example will make the test clear. Suppose we use a Clark standard cell of 1·435 volt. (The standard cell must be joined in opposition to the battery, as shown in Figs. 120 and 123). With $r=100$, we balance the galvanometer with R adjusted to say 3,178 ohms. Again, with $r=200$ balance is obtained say with $R_1=6{,}568$ ohms. Then resistance of battery is

$$6{,}568-(2\times 3{,}178)=212 \text{ ohms},$$

and E.M.F. of battery is

$$1{\cdot}435\left(1+\frac{3{,}178+212}{100}\right)=50 \text{ volts}.$$

It will be seen that the formula for the battery resistance when $n=2$ is the same as for the half deflection method. But there is the advantage that no deflection has to be read in this test, and further, the value of n may be made 3, 4 or other higher values up to 10 to suit different batteries, all giving equally accurate results on account of reading the galvanometer to zero instead of reading deflections. When it is desirable to make r any other value than 100, or n any other value than 2, a separate resistance box should be used. This box should be put in series with the resistance R and

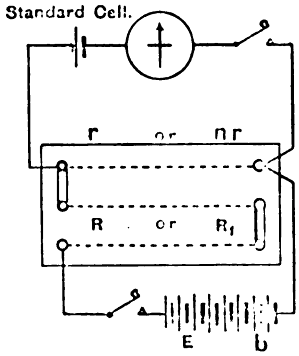

FIG. 123.

battery, and the galvanometer and standard cell connected across it. The maximum current put through the coils when r is 100 ohms is a very moderate one.

With a Clark standard cell of 1·4 volt the current is

$$\frac{1{\cdot}4}{100}\times 1{,}000=14 \text{ milliamperes}.$$

It will not be found necessary to make r less than 100 unless there is not sufficient resistance available for R, but in any case r should not be less than 50 ohms, which would cause a current of 28 milliamperes to pass through the coils when balanced.

To prevent an undue current being passed through the coils *before* the balance is obtained, it is advisable to calculate roughly what R should be. Knowing *approximately* the resistance of battery (b) and its E.M.F. (E), the resistance R should be about

$$r\left(\frac{E}{e}-1\right)-b \text{ ohms}.$$

For instance, we are to test, say, the resistance and E.M.F. of a battery of 40 cells. If they are good-sized Leclanché's they will probably have about 1·6 volts and 5 ohms per cell, or 64 volts and 200 ohms for the battery. Putting $r=100$ and using a standard cell of 1·4 volt we find that R should be about

$$100\left(\frac{64}{1{\cdot}4}-1\right)-200=4{,}270 \text{ ohms}.$$

Putting this approximate resistance for R at starting, its right value is soon afterwards found by adjustment until the galvanometer is balanced. A make and break key is put in the galvanometer circuit which must only be *tapped* while adjustment of R or R_1 is being made, in order to prevent any appreciable current leaving or entering the standard cell.

(To be continued.)

THE ABSOLUTE MEASUREMENT OF ELECTRICAL RESISTANCE.*

BY PROF. J. V. JONES, F.R.S.

§ 1. If we take a conductor such as this piece of copper wire, and make it part of a conducting circuit in which an electric current is flowing, we find that the electromotive force between its extremities is proportional to the strength of the current passing though it, so long as it remains in the same physical condition. If either the electromotive force or the current strength varies, the other of these quantities varies in like proportion. Their ratio is constant, *i.e.*, it has a value independent of them, and depending only on the dimensions of the conductor, the nature of the material of which it is made, the state of aggregation of its parts, and its temperature.

This ratio is called the electrical resistance of the conductor, and so defined it corresponds to a real physical quantity—it is a physical property of the conductor.

§ 2. Probably no physical measurement can be made with greater accuracy than the comparison of electrical resistances. Such comparisons are daily made in many parts of the world, and it is clearly desirable, in order that the results obtained by one man may have meaning for others, that all should make their reckoning in terms of the same unit. Accordingly, the scientific world has given great attention to the definition of such a unit, and much international negotiation has taken place with a view of securing world-wide agreement on this point.

The most obvious method of procedure is to fix upon some convenient conductor as a standard, and to call its electrical resistance the unit of electrical resistance, other electrical resistances being then expressed as so many times or such and such a fraction of the resistance of this standard conductor.

The disadvantage of this method of defining the unit is that the resistance of such a standard may change from time to time through alterations of its physical condition. The most notable change is consequent on change of temperature; this may, however, be allowed for by defining the unit as the electrical resistance of the standard conductor when it is at a specified temperature. But the other changes of physical condition, changes in the state of aggregation of the parts of the conductor, effects of strain, alterations of molecular structure, &c., are more serious, because they are unknown, and we cannot in our definition provide against unknown possible changes. We run the risk, therefore, of having a varying unit, and the prime requisite of a unit is constancy.

In England the Government has taken this risk, and committed itself—at least for the present—to this method of specifying the unit of electrical resistance.

The denomination of the standard of electrical resistance contained in the recent Order in Council regarding Standards for Electrical Measurements is as follows:—

"A standard of electrical resistance denominated one ohm being the resistance between the copper terminals of the instrument marked 'Board of Trade Ohm Standard Verified, 1894' to the passage of an unvarying electrical current, when the coil of insulated wire forming part of the aforesaid instrument and connected to the aforesaid terminals is in all parts at a temperature of 15·4°C."

This is a plain adoption of an arbitrary standard. The resistance of a certain piece of wire wound into a coil is made the legal unit, and if this resistance varies our legal unit varies with it.

It is true that in constructing the standard efforts have been made to ensure that its resistance shall be equal to 1,000

* Friday Evening Discourse, delivered at the Royal Institution, May 24, 1895

Digitized by Google

million times the absolute unit of which I shall presently speak—that the standard was in construction based upon the ohm; but there is no provision in the Order in Council for revision if the standard varies, nor indeed has the Government any means at its disposal of directly measuring its standard in absolute measure.

I seem to be finding fault. That is not my intention. I am only advocating progress. The time is ripe for the adoption of the absolute unit, not merely nominally but really, for the frank acceptance of the absolute unit itself as the ultimate legal standard.

§ 3. Now, what is an absolute unit? The following considerations affecting physical measurements generally will, I hope, serve to make this clear.

In order to specify the magnitude of any physical quantity, we bring it into relation with a standard magnitude of the same kind, called the unit, and say that it is so many times or such and such a fraction of this unit. Thus we speak of a length of 6 centimetres, a mass of 50 grammes, a time of 20 seconds, an electric current of 10 amperes, an electrical resistance of 30 ohms, and so on.

For the purpose of this specification any convenient magnitude of the physical quantity to be measured may be taken as the unit.

But science has to deal with many kinds of quantities, and when we consider the various units as constituting a system, our arbitrary choice is limited by two conditions of fundamental importance:—

(1.) The units must be chosen so as to simplify as far as may be the statement of the quantitative relations existing between various kinds of quantities.

Physical science, in so far as it is quantitative—may we not say in so far as it is perfected?—tells us of relations of interdependence between many different kinds of quantities. Thus, in geometry we have such relations between lengths, areas, and volumes; in kinematics, relations between these mathematical quantities and times, velocities, and accelerations; in dynamics, between these mathematical and kinematical quantities and mass, momentum, force, work, and energy; in electrical and magnetic science, relations between the foregoing quantities and electrical and magnetic magnitudes; and so on.

These relations of interdependence are expressed in equations, and it is of obvious advantage, both for ease of arithmetical calculation and clearness of thought, to rid these equations as far as possible of superfluous arithmetical constants. This may be done by a judicious selection of units, by making the units of the quantities that appear most complex in their relations of interdependence depend upon the units of the quantities that appear in their nature to be simplest. A unit of any quantity so defined with reference to the units of quantities apparently simpler is called a derived unit with reference to the latter units as fundamental.

Thus, the attraction of the earth on a mass of 1lb.—the weight of 1lb.—is an arbitrary unit of force. The force that, acting on a mass of 1lb., increases its velocity by 1ft. per second every second is a derived unit of force with reference to the units of length, time, and mass, as fundamental. It is usually called the absolute unit of force on the pound-foot-second system; and by the very nature of its definition it gets rid of an arbitrary constant in the relation between force, mass, and acceleration. If the arbitrary unit of force mentioned above—the gravitation unit—is used instead of the absolute unit, our dynamical equations are uselessly complicated by the introduction of "g," the acceleration of gravity at the particular point of the earth's surface at which we happen to be, and at the particular time when our measurements happen to be made.

(2.) The second condition of prime importance to a scientific system of units is that the units of all quantities should be invariable, unaffected by conditions of time and place, and independent of the properties of particular bodies, *i.e.*, they should be *absolute*. The word "absolute" is in philosophy opposed to "conditioned." When it is applied to a unit in science the implication should be that the unit is the same at all times and in all places, and that it is unconditioned by the properties of any specified body or bodies, *i.e.*, that its magnitude is brought into relation with and depends upon only the most permanent phenomena of the universe.

The modern system of absolute units goes far to fulfil the first of our two requirements; it only very partially fulfils the second.

When we speak of an absolute unit at present we mean a unit the magnitude of which depends on nothing else than the units of length, time, and mass, and the properties of the ether. The latter may be regarded as universal enough, but the units of length, mass, and time are arbitrary standards. The metre depends on the properties of a particular bar, the gramme on the properties of a particular piece of platinum, the mean solar second on particular bodies of the solar system.

The time will come when we shall be able to take another step forward, when we shall be in a position to make the unit of mass a derived unit with reference to the units of length and time as fundamental through that universal uniformity of nature—the law of gravitation; the units of length and time being based on some more permanent phenomena of the universe (the properties of the sodium molecule have, for instance, been suggested) than the length of a particular bar, and the motion of the earth on which we live.

But we cannot take this step forward yet. We do not know either the gravitation constant or the velocity of light with sufficient accuracy to enable us to define by means of them units precise enough to meet the needs of practical life. Yet the fact that if we knew these constants we could make an important advance in the realisation of a system of absolute measurement is an excellent reason why the masters of physical measurement should apply themselves to their precise determination.

The use of a derived unit of mass would have this among other advantages: it would rationalise the dimensions of the electric and magnetic units in length and time, and relegate the irrationality to the ether, to which I believe it properly belongs.

We must, however, for the present be content with a less complete reference to the most permanent phenomena of the universe, and by absolute measurement to-night I mean measurement in terms of a unit derived with reference to the unit of length, time, and mass as fundamental, *i.e.*, a unit conditioned only by these units, and the properties of the ether.

§ 4. There is such a unit of electrical resistance—a unit derived with reference to the units of length and time as fundamental—the magnitude of which is independent of the properties of any particular conductor, any particular coil of wire, and which is conditioned only by the units of length and time, and the properties of the ether.

It may, indeed, at first sight seem astonishing that a quantity so different can be expressed in terms of a length and a time. Yet so it is. We can, in virtue of experiments made 63 years ago in this Institution by Michael Faraday, measure the resistance of a conductor with the help of no other standardising instruments than a tape or measuring machine and a clock. An electrical resistance is always proportional to a certain velocity, and if the magnetic permeability of the ether be taken to be unity, the number expressing the electrical resistance will be the same as the number expressing that velocity; the unit of electrical resistance may then be taken to be the resistance corresponding to unit velocity, *i.e*, on the C.G.S. system a velocity of 1c. per second, and any electrical resistance may be conveniently expressed in terms of this unit as so many centimetres per second.

[You will observe that I do not say electrical resistance *is* a velocity. That would be to neglect the unknown dimensions of the magnetic permeability of the ether.]

If the unit of length, the unit of time, and the properties of the ether remain constant, this unit of electrical resistance remains constant. It is unconditioned by the properties of any material, by position in space, or point of time, and so far deserves the name of the absolute unit of electrical resistance.

§ 5. How comes it that resistance can be so measured? The answer to this question is best found in a description of some one of the methods by which the measurement of an

Digitized by Google

electrical resistance in terms of the absolute unit can be experimentally made.

And I proceed, therefore, to a description of the method which may fairly be described as the simplest, and which in my opinion, having regard to the magnificent possibilities of mechanical engineering operations in this country, is undoubtedly capable of being made the most accurate of all the methods that have been proposed since the British Association Committee, more than 30 years ago, propounded the theoretical definition of the absolute unit.

The method is due to Lorenz; and Lord Rayleigh, at the conclusion of his masterly determinations of the value of the B.A. coils in absolute measure, expressed himself in regard to it as follows:—

"On the whole, I am of opinion that if it is desirable at the present time to construct apparatus on the most favourable scale so as to reach the highest attainable accuracy, the modification of Lorenz's method last described is the one that offers the best prospect of success."

The Paper from which I quote contained a comparison of the various methods of measuring resistance in absolute units, and an invitation to others to join in the work. It was the starting point of my own researches in the matter, which have extended over some years, and I gladly take the opportunity of thanking Lord Rayleigh for this source of inspiration.

§ 6. Faraday discovered that, if a conductor is made to move in a magnetic field so as to cut across the flux of magnetic induction, the conductor becomes the seat of electromotive force, and that the electromotive force so developed is proportional to the rate at which the induction flux is traversed.

If, for instance, we take a metal disc and make it rotate about a horizontal axis n times a second, any radius of the disc cuts through the earth's induction flux, unless the plane of the disc is in the magnetic meridian. There will, therefore, be electromotive force between the centre and circumference of the disc. Further, since a radius traverses the whole area of the disc n times in a second, the rate at which the induction flux is being traversed by any radius is $n\,I$, where I is the total flux of induction through the disc area. But the electromotive force is proportional to this rate. Therefore we have (with a proper choice of the unit of electromotive force)

$$E_1 = n\,I,$$

where E_1 is the electromotive force between the centre and circumference.

But we may, instead of using the earth's field, obtain a magnetic field by means of an electric current. The disc may be made to spin in the magnetic field due to a current in a coil of wire placed so as to be co-axial with it, and so that its middle plane coincides with the plane of the disc. In this case the magnetic field is symmetrical with regard to the common axis, and we have once more

$$E_1 = I\,n,$$

where E_1 is the electromotive force between the centre and circumference consequent on the rotation of the disc at the rate of n turns per second in the induction flux due to the current in the coil, I being the total amount of that flux which passes through the disc circumference.

§ 7. Now the current strength in a given circuit is by definition proportional to the intensity of the magnetic field produced by it at any point, and hence the magnetic induction through the disc due to the current in the coil is proportional to the strength of that current.

It follows that the magnetic induction through the disc is made up of two factors, viz., the current in the coil and the magnetic induction that would pass through the disc if unit current passed through the coil. The latter factor is called the coefficient of mutual induction of the coil and disc circumference, and its value depends only on their dimensions and relative positions, and the magnetic permeability of the medium in which they are placed. If the latter quantity is taken to be unity the coefficient of mutual induction is expressible as a length, and it may be calculated from observations involving nothing else than measurement of the radius and breadth of the coil and the radius of the disc. Let this coefficient of mutual induction be denoted by M, and the current in the coil by γ_1; then

$$I = M\,\gamma_1,$$

and finally,

$$E_1 = n\,I = n\,M\,\gamma_1;$$

or

$$\frac{E_1}{\gamma_1} = n\,M.$$

§ 8. We have therefore two ways of expressing the ratio of an electromotive force to a current.

By definition (Ohm's law) this ratio is given to us as electrical resistance, or

$$\frac{E}{\gamma} = R.$$

By the experiment of the disc and coil it is given to us as the product of their coefficient of mutual induction and the rate of rotation of the disc (number of turns per second).

And if the ratio for the disc and coil is made the same as the ratio for the resistance (which it is possible in practice to arrange) we have

$$R = M\,n.$$

If the magnetic permeability of the medium be taken as unity, M is a length expressible as so many centimetres, and the number of turns per second is the reciprocal of the time of one revolution of the disc. Hence the resistance may be expressed as a velocity of M centimetres in the time of one revolution of the disc. This makes it clear that with the assumption in regard to the permeability of the ether (or air) that we have made above any electrical resistance is expressible as a velocity of so many centimetres per second.

§ 9. We can in practice make the ratio for disc and coil the same as the ratio for the resistance by first sending the same current through coil and resistance and then varying the speed of the disc so as to make the electromotive force between its centre and circumference equal to the electromotive force between the resistance terminals.

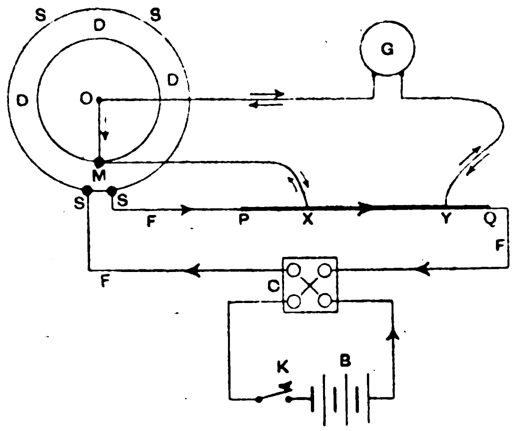

FIG. 1.

How can we test the equality of the two electromotive forces? If two equal electromotive forces act in opposite directions in the same circuit the result is electrical equilibrium. We have, therefore, to proceed as follows:—Place the two electromotive forces in the same circuit so as to act in opposite directions; then if they are the only electromotive forces in the circuit there will be an electric current round the circuit due to their difference if they are unequal, and no electric current at all if they are equal. The presence or absence of a current may be tested by the inclusion of a galvanometer in the circuit.

In practice it is not quite so simple as this, because it is impossible to make the two electromotive forces in question the only electromotive forces in the circuit. There will be others, and especially thermo-electric forces, always present. But this difficulty may be met thus:—Reverse the two electromotive forces we are comparing; if the current in the circuit is not changed by this reversal of both, they must be equal, *i.e.*, if the reading of the galvanometer be the same, whether the balancing electromotive forces are in one direction or the other, these electromotive forces are equal. The reversal of

Digitized by Google
E

both our electromotive forces may be readily effected in practice by simply reversing the direction of the current through the coil and resistance.

To measure our resistance in absolute measure we have then—

(1.) To make the coil (S S S, Fig. 1) and the resistance (X Y) parts of the same main circuit (B C F S S S P X Y Q C B), and to pass through this circuit an electric current. A commutator (C) is to be inserted in the circuit in order that the direction of the current may be changed at will.

(2.) To insert the electromotive force between the centre and circumference of the disc (D D D) acting in one direction and the electromotive force between the extremities of the resistance acting in the opposite direction in a second circuit (X M O G Y X) containing a sufficiently sensitive galvanometer G. Brush contacts must be made at O and M.

(3.) To vary the rate of rotation of the disc until the reading of the galvanometer is the same whether the current in the main circuit through coil and resistance is being sent by the commutator in one direction or the other.

(4.) To measure this equilibrium rate of rotation.

(5.) To multiply this equilibrium rate of rotation (number of turns per second) by the coefficient of mutual induction of the coil and disc, which is calculated once for all from their measured dimensions. This product gives the resistance to be measured in absolute units.

[The necessary arrangements were here experimentally shown by the lecturer.]

(*To be concluded.*)

THE ELECTROLYSIS OF HYDROCHLORIC ACID WITHOUT A POROUS SEPTUM.

The salient points in a short Paper by Dr. Felix Oettel, appearing in the *Zeitschrift für Elektrochemie*, may be summarised as follows:—

When hydrochloric acid (in aqueous solution) is electrolysed without a septum between the electrodes, the output of H and Cl falls considerably below the calculated value on account of the solubility of chlorine in water and its consequent ready union with the hydrogen evolved at the cathode. The loss can be somewhat reduced by increasing the current density at the cathode. Thus, using a 12 per cent. solution of HCl, the author found the following values:—

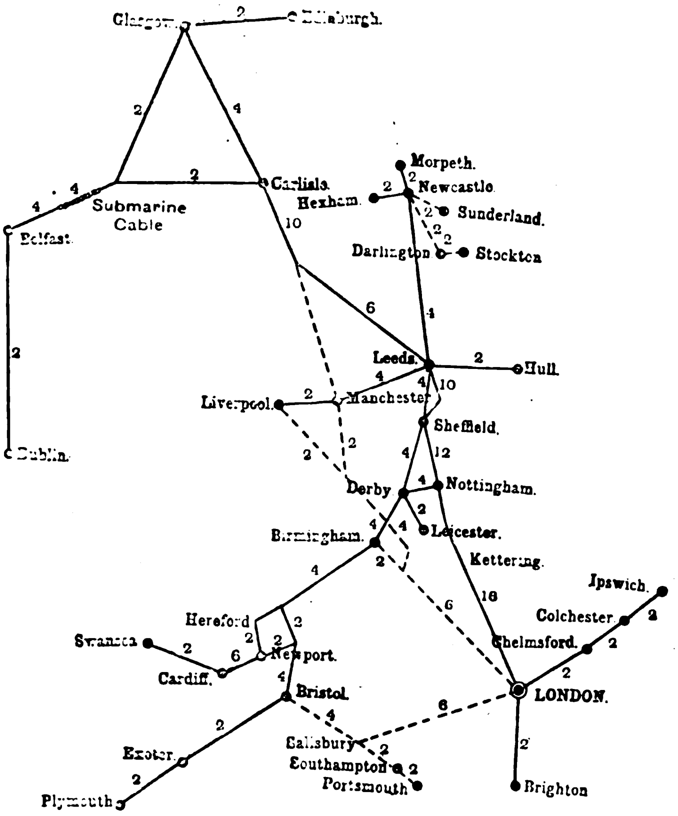
Current density. Amperes per square metre.	Output efficiency referred to current.	Voltage
	Per cent.	Volts.
240	41	1·4
600	55	1·6
1,200	66	1·7

A further advantage can be secured by diminishing the solubility of the chlorine by the use of an electrolyte containing some salt in solution in addition to HCl. A suitable solution is one containing 160grm. sodium chloride and 140grm. sulphuric acid per litre, partial decomposition taking place on the addition of the sulphuric acid, so that the substances present are HCl, NaCl and $NaHSO_4$. Using this as an electrolyte, an efficiency, referred to the current as distinct from the total energy absorbed, of 70 per cent. is obtained with a current density as low as 240 amperes per square metre, while when the current density is raised to 600 to 700 amperes per square metre the output is also enhanced, becoming 92 to 98 per cent. of that calculated from the current passing. Excess of sulphuric acid in the electrolyte causes oxygen to be evolved instead of chlorine, and, on the other hand, excess of sodium chloride causes eventually the production of sodium hypochlorite, the normal decomposition being determined. The highest efficiency is therefore obtained by working within comparatively narrow limits, such proportions as those given above being preferably adopted.

THE POST OFFICE TELEPHONE TRUNK WIRES.

On Wednesday afternoon the network of telephone trunk wires erected by the Post Office on the strength of the Treasury Minute of May 23, 1892, was formally "inaugurated" by the Lord Mayor of London conversing from the General Post Office, St. Martin's-le-Grand, with similar and similarly-situated municipal functionaries at Edinburgh, Glasgow, Belfast, and Dublin. What the conversations of these gentlemen related to is not accurately known, but it is reported to have had some reference to the weather.

The present and immediate future ramifications of the Post Office network are shown on the accompanying sketch map. The total length of wire required will be over 10,000 miles, and of this total 75 per cent. has already been erected. About one-



Post Office Telephone Trunk Lines.
Completed ——— In progress ········. Figures denote number of wires.

half of the 10,000 miles of wire runs 600lb. to the mile, the remainder being equally divided between 800lb. and 400lb. wire, the aggregate weight of copper being 2,829 tons.

The lines are all run on the "twisted" system, and where a large number of telephone trunk circuits are run on the same poles the circuits are also crossed at long intervals. The transmitter used is the Deckert, an Austrian improvement on the Hunnings microphone, and the receivers are simple double-pole Bell instruments. It may be mentioned that experiments have been made with a line extending 1,270 miles, from Plymouth to Dublin, by a circuitous and temporary route, and the results have proved satisfactory. This is the longest distance yet attempted, if we leave out the case of India, where the extreme dryness of the atmosphere gives facility for telephonic communication.

We may expect that, as soon as the telephone trunk system of this country has passed into the charge of the able heads which direct the telegraph system of the United Kingdom, the full capabilities of inter-urban telephony will be made apparent.

Royal Society.—The following Paper was down for reading yesterday:—Prof. S. P. Thompson, F.R.S., "On the Cause of the Differences in Lichtenberg's Dust Figures. Preliminary Note."

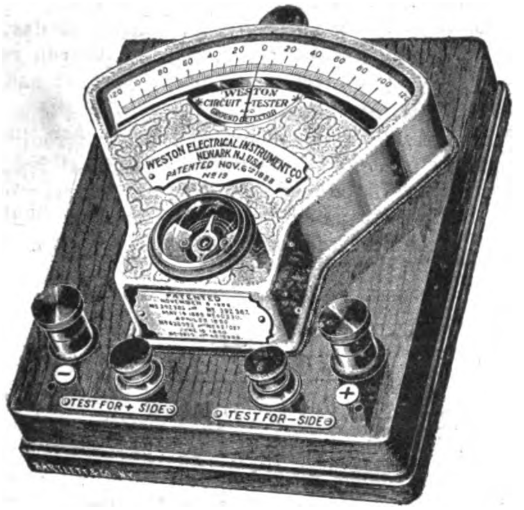
WESTON CIRCUIT TESTER.

Messrs. Elliott Bros. are introducing into this country several instruments made by the Weston Electrical Instrument Company, of Newark, N.J., and, amongst others, a circuit tester, or leakage indicator, for continuous-current circuits. The zero, as will be seen



Weston Circuit Tester.

from the illustration, is in the middle of the scale, and the two poles of the main being joined to the terminals direct, by depressing one of two keys either pole can be put to earth through a resistance of many thousand ohms, thus affording an easy means of obtaining information as to the state of the circuit under actual running conditions. The internal mechanism of this instrument is exactly the same as in the portable standard models with permanent magnets which are now so well known.

THE ELECTRICAL STANDARDISING, TESTING AND TRAINING INSTITUTION.

A dinner was given by the Electrical Standardising, Testing and Training Institution at the Imperial Institute on the 6th inst., under the presidency of Mr. Robert Hammond, in the absence, through domestic bereavement, of Lord Castletown of Upper Ossory. There was a large attendance, the company including Sir Courtenay Boyle, his Honour Judge Snagge, Col. Gouraud, Mr. Francis Ince, Mr. Ferranti, Prof. T. Hudson Beare, Mr. Musgrave Heaphy, Mr. P. W. d'Alton, Mr. H. A. C. Saunders, Mr. C. P. Sparks, Mr. G. W. Partridge, Mr. Albert Gay, Mr. W. W. Beaumont, and Mr. G. S. Ram.

The toast of "The Queen" having been duly honoured,

Col. GOURAUD proposed "The Electrical Standardising, Testing and Training Institution. In the course of a humorous speech he remarked that the Institution began with a much more modest name than it was at present known by, followed by the name of its founder, but the latter was a little "too previous." He himself (the speaker) once had the hardihood of bringing out a company with a million of capital, in 1882, with the object of lending money to people who wanted to go into this business. They obtained this capital from the public, and it was surprising the extent to which they had opportunities of lending it. In about a year's time, however, they found that there was not anything good enough to lend to, and they actually—this was an historic fact—called the shareholders together, and did something which he believed had never been done before in the history of English finance, and he was certain it would never be done again—they returned the capital to the shareholders, and informed them that they were ahead by ten years with their ideas. It was not their fault, but the fault of the British Government that they did not want at that time the electric light or the telephone; but they afterwards reformed their views. Mr. Hammond and his colleagues, seeing that their "too previous" idea in 1882 was about ripe in 1892, looked around them for the rehabilitation of the Institution, and in due course installed themselves at Faraday House.

The CHAIRMAN, in acknowledging the toast, remarked that Col. Gouraud had modestly put himself in the background, and had omitted to inform the company that among the enthusiasts who founded this industry he was himself one of the leaders. As the representative in this country of Mr. Edison, Col. Gouraud had done a very large amount of enthusiastic pioneering. The enthusiast had, perhaps, only one fault, namely, that he was often a burden to his family, for enthusiasm was not a thing that was always convertible into bank notes. Col. Gouraud had reminded them that the present Institution was founded upon the lines of the old Hammond Electrical Engineering College. In 1882 there were no skilled assistants to carry out the work that had to be done, and he (the speaker) could only be in one place at a time. There were, however, numerous jobs waiting to be executed. In 1881 he formed the idea that all the processes of rail making could be carried out in one shift in 24 hours if only the electric light was put on the rail bank. He conclusively proved at Middlesborough the correctness of this idea, and a few months afterwards every rail bank was illuminated by the electric light. This necessitated assistants; but they were not to be had, and the old Hammond College was then founded with the idea of manufacturing them. It was not until 1890, however, that they started the old College under its present happier name. They got hold of the enthusiasts in the form of students, and he thought there were men in the industry who would agree that that branch of the Institution's work had been a success. There were other enthusiasts in the industry besides students; there were the inventors. In those early days they had a primary battery offered to them every week. Inventors came to the Institution and took up the whole of their time, and he remembered saying to Lord Crawford, his colleague in restarting the Institution, "Let us found a primary battery repression society." Lord Crawford, however, on the contrary, suggested that they should test these primary batteries and other inventions and report on them. Having gone as far as that, they thought they might report on all inventions, and next they thought that they might standardise and put right the instruments of others. In every department of Faraday House they had placed all their resources at the command of those who were working out a new and useful invention.

Mr. FRANCIS INCE next proposed "The Visitors," and his Honour Judge SNAGGE replied.

The CHAIRMAN afterwards proposed "Past and Present Students." Some persons, he remarked, seemed to think that the electrical industry was played out, and that young enthusiasts who felt that they would like to be electrical engineers were likely to waste their time. He would endeavour to combat that opinion. In 1882, when the old Hammond College was first founded, there was only one house in England, if not in Europe, which was lighted from coal cellar to attic by the electric light, that house being either Colonel Gouraud's or his own. Since 1882, however, the electric lighting industry had shown such marvellous growth that at the present time there were 99 central stations for the supply of electricity for lighting and other purposes in the United Kingdom. Of these 55 were in the hands of companies, and 44 were in the hands of Corporations or Local Authorities. Not only had some £7,500,000 come into the industry in the same time, but the prospect before it was as bright as anything which it had achieved in the past. He believed that in the next 10 or 20 years they might look for an addition to the electrical plant of the country to the extent of £500,000 per annum. There were two other domains in which electrical engineering had an immense future—in the direction of the distribution of electrical power, and in the direction of electric traction. The students might be assured that a great field lay before them.

The toast was acknowledged by Mr. STOTHERT and Mr. GLADSTONE.

Sir COURTENAY BOYLE afterwards proposed "The Board of Control and Staff." He expressed his great satisfaction in proposing the toast, as he claimed that of all the multifarious duties which devolved on him at the Board of Trade—duties extending from China to Peru, and over all phases of commerce and functions of trade—there was none which gave him more interest than that which appertained to the electrical industry. Ten years ago, when he joined the Board of Trade as assistant secretary, the industry was not as flourishing as it was now. It might have been that the Act of 1882 did not achieve the result expected of it; but the position was very different now. Powers of supply and of lighting were given to and enjoyed by a large number of companies and municipalities, and he claimed that the Board of Trade had built up a code of law governing those bodies which was acceptable, which was working well, and which was successful in every point of view. During the last 10 years, too, the Department had produced an international agreement as regarded the ohm, the ampere, and the volt, and by doing this they had settled three standards which were extremely useful to the electrical industry. They had further—at least for the moment—pacified that quarrel of many years' duration which had existed between the telephone industry and electric traction as to the user of earth. He thought that no students were to be more congratulated than those who had to do with the advancement of electrical energy. He believed that the field which lay before them was unlimited and unexplored, and that it devolved on men like themselves to cultivate that field in the way it ought to be cultivated, and to produce from it those results which were obtainable therefrom. As long as their Institution was presided over by men like Mr. Harrison, he felt sure that it would prosper and succeed.

The toast was acknowledged by the CHAIRMAN, Mr. INCE, and Mr. HARRISON, and the company shortly afterwards separated.

PARIS NOTES.

(FROM OUR OWN CORRESPONDENT.)

PARIS, *June 10, 1895.*

Electric Tramways for Montmartre.—The city of Paris will at last be endowed with an exemplar of the conduit system of electric traction. As the result of a competition for the laying down of an electric tramway starting from the foot of the Butte Montmartre, Place Cadet, and going through the Rue Rochechouart, to finish at the opposite slope, two projects were sent in and examined, and the concession for the line has been granted to the Société d'Etudes Françaises et Etrangères, who offered to pay the highest royalty to the municipal authorities.

Heilmann System of Electric Traction.—The Compagnie des Chemins de Fer de l'Ouest has granted to M. J. J. Heilmann a concession for the overhead system of electric traction on the line Saint Germain—West to Saint Germain—Grande Ceinture. This line is a double-track road, and has been established quite recently; it has a length of 4 kilometres. An 800-H.P. plant will be installed at Saint Germain (West).

Condensers in Commercial Use.—The Secteur Électrique des Champs Élysées has employed for some time successfully a battery of condensers in series with the feeders in order to reduce the current when the secondary circuits are not loaded. Before these condensers, constructed by M. Boucherot, were added the current was equal to that of a 400-kilowatt alternator at full load. The same supply company has in view the laying down of an alternator for the purpose of compensating the disturbances due to want of synchronism of the alternators.

A Large Dynamo.—The Edison Company, after having obtained from the leading dynamo builders estimates and drawings of a 2,000 ampere 150 volt double dynamo for their Trudaine station, have placed the order with the Société des Etablissements Weyher and Richemond. This dynamo, of the Brown type, will be provided with two commutators for the purpose of feeding the three-wire distribution, and consequently will yield 2 × 2,000 amperes at 150 volts. It will be driven direct by a Van der Kerchove engine at a speed of 100 revolutions. The guaranteed steam consumption is 9·85kg. per utilised kilowatt-hour.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *June 1, 1895.*

The Telephone Situation.—The recent decision in the Berliner case has brought about a movement having in view the general organisation of telephone manufacturers and operating companies adversely affected for mutual protection against the American Bell Company. In the absence of the opinion of the Court, which will not be handed down for some days yet, the full effect of the decision rendered cannot be known, but on the face it appears to extend the telephone monopoly in this country until 1908. It is most probable, however, that this monopoly will not be established without a desperate struggle on the part of the numerous manufacturing and operating companies who had made large investments on the strength of Judge Carpenter's decision, nullifying the Berliner 1891 patent. This at least will probably have the effect of determining the real status of the Bell patents, which number perhaps over a thousand. While little is known about the most of these patents, yet even a cursory examination shows that many of them are of the kind so frequently issued in the early days of telephony and electric lighting, in which the only inventive skill exercised was in drawing up claims to cover "old chestnuts."

The American Institute of Electrical Engineers.—The geographical distribution of the officers of the American Institute of Electrical Engineers who were elected last week emphasises the national character which that body has attained. Until within a few years it was little more than a local New York affair, and the formation of the Chicago branch meeting may be considered as the first great step toward a broader sphere of influence. Another branch meeting will soon be organised, and it is quite probable that within a couple of years there will be a half-dozen such local meetings, thus greatly extending the influence and usefulness of the body. Of the newly-elected officers, President Duncan is from Baltimore; Vice-Presidents Pupin, Hasson, and Hebbard are from New York, San Francisco, and Chicago; and Managers Hering, Scott, Hutchinson, and Arnold are from Philadelphia, Pittsburg, New York, and Chicago respectively. The general meeting of the Institute will be held in Niagara Falls the last week in June, and will be one of unusual interest from the fact that Papers on almost all of the various technical features of the Niagara plant will be read, the Niagara Company and the several contracting companies having reserved the announcement of much technical information for this occasion.

CORRESPONDENCE.

ARMATURE DESIGN.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I was particularly interested in your comments on the Paper on "Improvements in Armature Ventilation," by Prof. Harris J. Ryan, which appeared in *The Electrician* dated May 31, 1895.

Inasmuch as I was the chief designing engineer of the Edison General Electric for some time previous, and until the consolidation of that Company with the Thomson-Houston Electric Company, some comments from me on this subject may be of interest, especially since it was during this period that the change from bipolar to multipolar dynamos was commenced on a large scale. My experience confirms the statements made by you. I shall be glad, however, if you will allow me to discuss these statements, since I judge them to be of considerable practical importance.

First, with respect to the time required by an armature when under load to attain its maximum temperature. In machines of the same type the time increases with the volume of metal in the armature, but not, so far as I have been able to ascertain, by any ascertainable law. Small armatures usually attain maximum temperature after three or four hours; larger ones generally require from8 to 12 hours, and occasionaly longer. In the Edison it was and in the General Electric Company it is the practice to test each new type of armature until it has attained its maximum temperature.

With reference to the 75°C. increase, I may state that this is not considered by American engineers a normal nor a safe increase of temperature. Such machines are considered to be of an obsolete type; 30°C. increase is nearer the standard practice of to-day. The new machines are perhaps no more efficient than the old, but they certainly are more durable.

With reference to the standard speed of 3,000ft. per minute, I may state that this was true in the case of the bipolar type, but in the new types the peripheral speed varies with each class of dynamo. For direct-connected machines 2,500ft. per minute is an average value. For belt-driven machines of higher speeds 3,200ft. is a fair average. The peripheral speed of the armatures of commutating machines seems to be a function of the angular velocity, and in alternators a function of the frequency. I entirely agree with your statement, that a really satisfactory basis on which to estimate the cooling surface of armatures and to allow for different speeds of rotation is still to seek. The best approximation that I have been able to make from a great number of tests with the older type bipolar dynamo of larger size is: peripheral speed, 3,000ft. per minute, the increase of temperature per watt per square inch is from 30°C. to 40°C., and for 2,000ft. per minute 36°C. to 48°C. With the modern ventilated type the increase of temperature calculated in the same way is about one-half.

In a certain series of experiments on armatures with ventilating flues of the same type it was found that the ventilation increased approximately with the square root of the surface

speed. With the non-ventilated type I have been unable to satisfactorily to determine any law of the effect of peripheral velocity on increase of temperature.

With reference to the eddy current loss, this seems to vary in importance according to the size of the dynamo, and is of more or less importance according to the construction. In the larger Edison dynamos Foucault-current heating was troublesome, whereas in the smaller ones it was of practically no importance, since these machines were generally designed for small current output.

The present proportions of armatures have been determined principally with reference to the sparking limit. The maximum current output per pole is a limited quantity, and the number of poles has been increased to the present limit to suit the more exacting practical conditions as to sparking. Dynamos of half the number of poles, and with longer armatures of smaller diameter, could be made to be sufficiently cool; but they would be less satisfactory as to sparking. Great current output with small trouble from sparking can only be secured by a great number of poles, which is the natural complement of a short armature of large diameter.

I am not of opinion that such devices as commutating lugs and face winding are necessary to balance a dynamo (even with ventilating flues) so that the sparking and heating limit occur at the same output. As an example I would instance an 800-kilowatt railway dynamo designed by the writer and tested by the jury of awards at the Chicago Exposition. The armature losses were as small as the outside dimensions permitted, and small considering the output of the dynamo; every precaution had been taken to effectively ventilate the armature and commutator, yet the sparking was not noticeable for outputs considerably beyond the limit of output determined from the safe heating limit 40°C. Other machines constructed on the same lines have shown the same qualities. My own experience with commutating lugs has been unsatisfactory. In estimating the worth of such contrivances the cost of material and labour have both to be considered. Unless extra windings save a great part of the material, the complication of the dynamo is increased without commercial advantage.—Yours, &c., H. F. Parshall.

June 11, 1895.

ZICKLER'S UNIVERSAL ELECTRODYNAMOMETER.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: On page 75 of your issue of May 17th you published a long abstract from my pamphlet on the universal electrodynamometer designed by me, and you also referred to the same in your Editorial Notes on page 71 of the same issue. Permit me to make a few remarks with reference to the latter.

The conditions which an instrument for measuring potential has to fulfil, and which have to be considered in the construction of the same, are well known to me. They are comparatively easy to comply with when the instrument is only intended for measuring potential. In the case of the electrodynamometer here considered, however, the conditions take the following form. If, first of all, mirror-reading is supposed, then the watt loss and the influence of the self-induction can be made very small. In direct-reading electrodynamometers, torsion electrodynamometers, and electrodynamic current weighers, it is easily possible to bring the maximum watt loss down to about 0·1 watt for every volt of the potential to be measured. As an instance of this I may mention the centi-ampere balance of Lord Kelvin, where the same is used as a voltmeter. Again, the influence of self-induction in potential measurements of alternating currents can, with medium periodicity, be easily confined to a small percentage of the potential to be measured. An instance of this is the astatic potential dynamometer of Siemens and Halske, which, with alternating currents of 50 to 80 periods per second, show only 2 to 3 per cent. difference in the readings for continuous and alternating currents.

Considerably greater difficulties are caused in this direction when it is required to construct an instrument which, besides potential measurements, also permits of measuring current and electric power (watts) between very wide limits. One is generally obliged to make larger concessions with regard to watt loss and the influence of self-induction. We find, for instance, in the composite balance of Lord Kelvin, which serves for current, potential, and watt measurements of continuous current, a maximum watt loss of 0 5 watt for every volt of the potential, though this instrument has no conductor for big currents in the movable coil, but requires an auxiliary current to be taken through the movable coil when measuring big currents.

The result attained by my instrument of a maximum loss of 0·4 watt per volt of the potential is therefore better than the result of the above-mentioned universal instrument, the more so when one considers that even the biggest currents are conducted through the movable coil, and no auxiliary current is required.

The most unfavourable feature in the universal instrument, as compared with a simple potential electro-dynamometer, is the greater weight of the movable coil, which consists of a copper frame of 35 square millimetres, and 60 turns of a wire 1·2 millimetres thick. This requires, as you very truly remark, in order to attain a certain sensibility, a powerful spring, and therewith likewise the turning moment is settled, which the current-carrying coil has to exercise upon the movable coil. Having settled upon a suitable maximum for the voltmeter current, then the product $m_1 \times m_2$ of the number of turns of the fixed and movable coils will have a certain value. Theoretically speaking, then, other conditions being the same, the coefficient of self-induction of the coils is smallest when the sum of the turns $m_1 + m_2$ is a minimum. This is the case when $m_1 = m_2$. To get near this favourable point in practice without increasing the weight of the movable coil, the same can be made of *aluminium* instead of copper. An instrument of this kind is already in the course of construction, and, owing to the increase of windings of the movable coil and the decrease of the windings of the fixed coil, more favourable results in potential measurements of alternating current in respect to self-induction will be arrived at, so that, for instance, at the same torsion angle the variation between the readings for continuous current (600 volts) and alternating current at 100 periods should no longer be 50 per cent. (900 volts), but only 2 to 3 per cent. At the same time the watt loss in the instrument will become smaller. In future, therefore, all instruments will be so constructed that the influence of self-induction and the watt loss of the instrument will be confined within the desirable limits. This universal instrument should therefore be of great service to electricians in all those cases, which often occur, where no suitable instrument for the special measurement in hand is at their disposal.—Yours, &c., Karl Zickler.

MAGNETIC TESTERS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I notice in the reports given in your valuable journal of the discussion on Prof. Ewing's Paper on a "Magnetic Tester," Prof. Forbes speaks of an apparatus made here some years ago and used by the General Electric Company, accrediting me with the design. I wish to say that the design of the instrument was due to Mr. Frank Holden, who was employed in the instrument department of the Company, and that he intends shortly to write a description of the instrument and give the results which he has obtained in its use.

Prof. Forbes's error in accrediting this instrument to me was natural under the circumstances, as I had spoken to him of another instrument made some years previously—I think in the latter part of 1889 – in which a pile of discs of standard size were driven in magnetic fields of varying strength by a small electric motor on the principle of the motor used in my recording wattmeter. A reading of the current required to be passed through the meter motor to overcome friction at any speed, in the absence of any magnetic field acting on the discs, was first taken, and another reading when the field was present. From the difference of these two readings the energy used in revolving the discs was easily obtained. Mr. Holden's instrument, however, is much nearer the simpler instrument proposed by Prof. Ewing.—Yours, &c., Elihu Thomson.

Lynn, Mass., May 31, 1895.

THE REVISED BOARD OF TRADE REGULATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Having a suggestion to make with regard to the new Board of Trade Regulations, and being neither a central station engineer nor one of the others interested who received a copy of the Regulations from the Board or the "whip" from the Electrical Trades Section, I beg leave to make it in your "Correspondence" column. Might not a regulation be added for the benefit of the central station people to the effect that, in house installations made after the date of the adoption of the revised Regulations, all single-pole switches and cut-outs should, so far as possible, be placed on the positive wire (or on the neutral wire in connections on the negative side of a three-wire network)?

I also think that, in view of the few accidents that happen, the use of the word "undertakers" in the high-pressure regulations (for instance, in No. 38) might be avoided, as it must unnecessarily jar on the nerves of those not accustomed to legal terms.—Yours, &c., C.

June 10, 1895.

LEGAL INTELLIGENCE.

Shelfer v. City of London Electric Lighting Company, and Meux's Brewery Company v. Same.

In the Court of Appeal on Wednesday, the Court consisting of Lords Justices Lindley, Lopes and Rigby, the cases of Shelfer *v.* City of London Electric Lighting Company and Meux's Brewery Company *v.* City of London Electric Lighting Company came on for hearing on motions by the defendants for leave to further stay the injunction which had been granted.

Mr. MOULTON, Q.C., told their Lordships that these were applications to suspend the injunctions granted in December last against the City of London Company on account of the nuisance caused to the plaintiffs by the vibration of the defendants' engines. The injunctions had been suspended for a month pending an appeal to the House of Lords, but in February last the defendants changed their manager, and employed a Mr. Frank Bailey, and he informed the Company that it was possible to stop the vibration complained of, and under these circumstances an appeal to the House of Lords was useless, so an extension of the suspension of the injunction was obtained to the first day of the Easter Term. The mode of stopping the vibration was by bringing about a radical change—viz., that the four large vertical engines near the "Waterman's Arms" were to be replaced by Parsons' steam turbines. What he (the learned counsel) asked for was that the injunctions be further suspended until the alterations could be carried out.

Lord Justice LOPES: What is to be done in the interval? Are the vibrations to continue?

Mr. MOULTON: We will do our best, and make the alterations as quickly as possible. Counsel suggested that the vibration was caused by the water under the soil.

In reply to Lord Justice Lopes, Counsel said that the contemplated appeal to the House of Lords had been withdrawn.

Mr. WARMINGTON, Q.C., for Mr. Shelfer, said that he was not treated fairly in this matter. Everything had been done to expedite the appeal, and on the last day for lodging causes it had been withdrawn. Nothing had been done; this engineer had been employed by the defendants since last February, and the nuisance complained of was still existing. This case had been compared to the well-known Manchester-square case, but there was no analogy between them, for in the latter there had been no vibration. Mrs. Shelfer's health had been much impaired, though at present the nuisance was somewhat mitigated, owing to it being summer. The steam from the defendants' works filled the house, making everything damp and dirty.

Lord Justice LINDLEY: How long will it take to move these engines?

Mr. MOULTON: One has gone already; we will remove them as quickly as possible.

Counsel went on to point out to their lordships the necessity of keeping a good supply of electricity in the mains for the public to draw from, and perhaps it would be advisable for the learned judges to nominate some engineer to estimate the time it would really take to remove them.

Lord Justice LINDLEY, in giving judgment, said that in this case the duty of the Court was not difficult to express. It was bound to see that private rights were not infringed, and also that public bodies were duly protected from oppression. Although not much impressed by the proposed turbines, he was satisfied that the efforts of the defendants to get rid of the nuisance were *bona fide*. Under the circumstances, however, he thought it right that the defendants should give an undertaking to answer as to damages. The injunction would be further extended to August 5th, the defendants undertaking to pay the costs of the applications.

Lords Justices Lopes and Rigby concurred.

Mr. Warmington, Q.C., M.P., Mr. Badcock and Mr. Waggett appeared as counsel for the plaintiffs; while Mr. Moulton, Q.C., M.P., Mr. Renshaw, and Mr. M. C. Braithwaite represented the defendants.

Direct Spanish Telegraph Company (Limited) v. The Owners of the Steamship "Caloric."

The plaintiffs are appealing in this action, which was tried before Mr. Justice Day in March last, and was brought to recover damages for alleged injuries to one of the plaintiff Company's cables in Bilbao Bay, by reason of the anchor of the "Caloric" fouling the cable whilst the vessel was lying at anchor. His Lordship found for the defendants on the ground that there was no negligence on the part of the defendants' servants, and it is against this decision that the appeal is taken.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

SPECIAL NOTICE.—The 1895 (thirteenth) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. In addition to the old well-known features of the book, which are brought up to date, a quantity of new and useful matter has been added, rendering the book more than ever indispensable to the Electrical, Engineering, and Allied Trades. Price, 7s. 6d., post free 8s. 3d., abroad 9s.

The following New Books and Editions of "THE ELECTRICIAN" SERIES *can be obtained of the Booksellers or direct from the Publishing Offices:—*

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett (*now ready*). Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

A LARGE-SHEET TABLE, giving full particulars of the Electricity Supply Stations throughout the Kingdom, can now be supplied mounted on stout board, with cord for hanging. Price: Varnished, 3s. 6d.; Unvarnished, 3s. —each post free. A Map showing positions of Supply Stations throughout the country is mounted on the back of the Table, and a Coloured Map of Metropolitan Electric Lighting Areas and a large sheet of Electricity Supply Statistics are also mounted on some copies, the price of which complete, post free, is 5s.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell, with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 250 illustrations. Price 10s. 6d. post free (abroad 11s.).

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d. post free.

"ELECTRO-CHEMISTRY."—This useful work, by Dr. G. Gore, is still on sale, the price being 2s., post free.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—By Mr. F. Marten Weymouth, is also ready; price 7s. 6d (abroad 8s.). Prospectus on application.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson, price 6s. 6d., post free.

"THE ELECTRICIAN."—A special notice concerning certain changes in the price, &c., of this journal will be found on page 228.

TENDERS INVITED.—The Electric Lighting Committee of the Corporation of St. Helens (Lancs.) invite tenders for the supply and erection of boiler and engine-house plant, switchboard and instruments, underground work (including cables, boxes, culverts, &c.), transformers and fittings, meters, and overhead crane for their electric lighting station. Specifications, plans, &c., can be obtained from Mr. Robert Hammond, the consulting engineer to the Corporation, Ormond House, Great Trinity-lane, London, E.C., and tenders are to be sent in to Mr. W. J. Jeeves, Town Clerk, Town Hall, St. Helens, not later than Tuesday, July 2nd. Some further particulars appear in our advertisement columns.

———— The Electric Light Committee of the Bedford Corporation invite tenders for the supply and erection of water-tube boilers,

Digitized by Google

engines, and alternators, of which particulars are given in our advertisement columns. Specifications and particulars can be obtained at the offices of Mr. T. S. Porter, Town Hall, Bedford, to whom tenders must be delivered by Tuesday, the 25th inst.

TENDERS INVITED.—The Urban District Council of Clevedon require tenders for the public lighting of their district every night in the year from sunset to midnight. The tenders are to be for one, two, or three years, and must be sent in to Mr. H. C. Fry, Clerk of the Council, Clevedon, by July 1st. Further particulars are given in our advertisement columns.

——— The General Direction of Spanish Posts and Telegraphs are inviting tenders until July 5th for the supply of 25,000 zinc cylinders for Callaud batteries. Also by the 4th prox. for the supply of 10,000 grey and 40,000 white porcelain insulators. Tenders are to be addressed to the Registro General, Direccion General de Correos y Telegrafos, Madrid.

——— The Corporation of Birkenhead require tenders for the erection and completion of the boiler-house and other buildings, &c., in connection with their electric supply stations. Tenders must be in by 12 o'clock Thursday, the 27th inst.

——— The Gas and Electricity Supply Committee of the Bradford Corporation require tenders for the supply of coals, for use at the electricity supply station for a period of one or two years, commencing from August 1st next. Tenders must be sent in to Mr. W. T. McGowen, Town Hall, Bradford, not later than Wednesday, the 3rd prox.

——— The Corporation of Preston require tenders for the wiring of the Town Hall and Public Hall buildings, and for the electric light fittings required for the installation. Tenders must be sent in to the Town Clerk, by noon of July 1st.

TENDERS ACCEPTED.—The Brighton Corporation have received the following tenders for the supply and erection of arc lamps, switches, &c. :—

Sharp and Kent, London (accepted)	£2,167
Crompton and Co., London	2,633
J. A. Edmundson, Leeds	2,757
Siemens Bros. and Co., London	2,988

Tenders were also received from Messrs. Johnson and Phillips and the Electrical Company, but, being informal, were not entertained.

——— The Birkenhead Town Council have accepted the following tenders :—

Tetlow Bros., Hollinwood (three Lancashire boilers)	£1,745
Crompton and Co. (Limited) (three sets of steam dynamos, engines, and feed pumps)	4,987
Crompton and Co. (Limited) (instruments, apparatus, wires, &c.)	798
Electrical Power Storage Company (Limited) (accumulators)	837
Callender's Company (cables, street boxes, &c.)	4,894

——— The Halifax County Council have accepted the tender of the Electric Construction Company for the supply and erection of a combined alternator and engine for the electricity works for the sum of £3,050. This additional plant is to be fixed by October, as it is anticipated that provision will have to be made for no less than 6,000 additional electric lamps for the coming winter.

——— The Museum Building Committee of the Exeter City Council have accepted the tender of the Electrical and General Engineering Company for carrying out the installation of the electric light at the Museum for the sum of £299. 10s. The tenders were not advertised, the selection being left with the architect.

——— The tender of Messrs. R. E. and C. Marshall, for wiring and fitting up the electric light at the Cheltenham Public Library, has been accepted for the sum of £105. 10s. 6d.

——— Eight tenders have been received in connection with the lighting of the Cardiff Free Library, and the tender of Messrs. Knapman, Hodder and Co., Cardiff, being the lowest, has been accepted.

——— Twenty-seven tenders were received for the wiring of the Shoreditch (London) Town Hall, ranging from £848 to £178. The latter, the tender of the Electrical and General Engineering Company, was accepted by the Vestry at its last meeting.

——— The Yarmouth Town Council has accepted the tender of Messrs. Lawrence Scott and Co. for the supply of electric fittings, &c., required for lighting the Beach gardens, for the sum of £14. 7. 6d.

SALE BY AUCTION—Under an order of the High Court of Justice Mr. William Izard (Messrs. Izard and Izard), of 52, Gracechurch-street, London, E.C., will sell by auction on *Tuesday next*, June 18th, at 12 o'clock, the valuable and extensive stock, plant, and machinery of the Ford-Lloyd Manufacturing Company (Limited) at Phœnix-place, Mount-pleasant, Clerkenwell, E.C. Some further particulars are given in our advertisement columns.

APPOINTMENT VACANT.—The Streets Committee of the Commissioners of Sewers are about to appoint a working mechanic for their electrical laboratory. Applications must be sent in by 12 noon, Tuesday, July 2nd. Some further particulars will be found in our advertisement columns.

APPOINTMENT VACANT.—The Vestry of Shoreditch, London, E.C., require a clerk of the works, with practical experience, to supervise the works in connection with the dust destructor and electric lighting station buildings, at a salary of £3. 3s. per week. Applications must be sent in to Mr. H. M. Robinson, Town Hall, Old-street, London, E.C., not later than noon of the 24th inst.

APPOINTMENT.—Mr. Charles D. Copland has been appointed works manager at a salary of £180 per annum, and Mr. Horace Taylor assistant works manager at a salary of £130 per annum, at the electric supply station of the Newport (Mon.) Borough Council.

PERSONAL.—We understand that Mr. F. R. Davenport has recently returned to the British Thomson-Houston Company, with whom he was formerly engaged. Mr. Davenport has for some time been acting as assistant to Mr. W. H. Preece in connection with the consulting electrical practice of the latter, and he was closely connected with the construction of the electric supply stations at Worcester, Tunbridge Wells and other places as Mr. Preece's representative.

LIQUIDATIONS.—A meeting of the creditors and contributories of the Anglian Carbon Company (Limited) takes place at 10, Meadowside, Dundee, on July 8th, at 3 p.m., to receive an account of the winding-up proceedings.

——— A meeting of contributories and creditors of the Schanschieff Electric Battery Syndicate (Limited) will be held at 32, Poultry, London, E.C., on July 10th, at 12 o'clock, to receive an account of the winding-up.

REMOVAL.—The general offices of Dalziel's News (Limited) have been removed to 15, Moorgate-street, London, E.C.

AGENCY TRANSFER.—Mr. N. G. Thompson, electrical engineer, of 13, Victoria-street, London, S.W., whose name is well known in connection with the London agency of electrical supplies, has disposed of his supply and agency business to Messrs. J. C. Lyell and Co., of 55, Victoria-street, S.W. Mr. Thompson will in future give his whole attention to professional work as a consulting engineer, his address remaining at 13, Victoria-street, S.W.

SOLD.—Yesterday Messrs. Hibbard and Son, of 9, Walbrook, E.C., sold without reserve the stock of electric lamps, shades, fittings, &c., the property of the creditors of Poole and White (Limited), Bread-street, Cheapside, E.C. The probability, however, that the creditors will receive any benefit from the sale is very remote.

TUMBLER SWITCH.—Under date 11th inst., we are informed by the General Electric Company that the action for infringement of the Link Switch patent against Messrs. W. McGeoch and Co. and others has been satisfactorily settled. Messrs. W. McGeoch and Co., Verity and Sons, Evered and Co., and the Edison and Swan Company are licensees for this patent.

VICES AND GENERAL ENGINEERS' TOOLS.—Messrs. W. H. Willcox and Co. issue an illustrated descriptive pamphlet of a variety of parallel vices manufactured by the firm. From the very large number of these tools in use it is clear that the engineering trade appreciate Messrs. Willcox's efforts to supply a first-rate article at a low price.

ARC LAMP CATALOGUE.—Messrs. Girdlestone, Tatham and Co., sole manufacturers of Andersen's patent arc lamps, send us their latest list, which gives illustrations and particulars of a variety of lamps suitable for indoor and outdoor lighting. The list is accompanied by testimonials from a number of users, including Messrs. Willans and Robinson, of Thames Ditton. The Exhibition of Railway Appliances, held at the Imperial Institute, was lighted entirely by these lamps.

IMMISCH ELECTRIC LAUNCHES.—The Immisch Electric Launch Company (Limited) send us a copy of a pamphlet descriptive of the Company's launches on the Thames, which, in addition, contains a number of time-tables, maps, and up-river fixtures.

"THE ENGINEERING MAGAZINE."—The contents of the June issue of this magazine (now ready) will be found to quite equal those of its predecessors in interest and variety. The articles include: "The Malignant Effects of the Free Silver Delusion," by Edward Atkinson; "The Growth of American Export Trade," by T. A. Eddy and Carl Schurz; "Irrigation Surveying in California," by C. E. Fowler; "Practical Hints for City Officials," by Francis Collingwood and Rudolf Hering; "Power, Light and Heat in City Blocks," by J. E. Talbot; "Wooden Stavepipe for Conveying Water," by Arthur Lakes; "Heating and Ventilating Tall Buildings," by L. Allen; "The Advances in Modern Iron Smelting," by John Birkinbine, and "Hints for the Mechanic and the Employer," by Edwin Woodward. Many of these articles are handsomely illustrated; and the magazine also contains a complete index of the contents of the World's Technical Press. The new number and nearly all back issues may be obtained at the offices of the European edition, 1, 2 and 3, Salisbury-court, Fleet-street, London, E.C.; price 1s. (post free 1s. 3d.) monthly, or 12s. 6d. annum (post free).

Digitized by Google

AYR.—Sanction has been given by the burgh authorities for extensions of the electric lighting mains at an estimated cost of about £990. It is expected that current will be available by the beginning of September.

BATH.—The new Municipal Buildings, which have been built at an outlay of £32,000, were opened on Tuesday. The electric light is used throughout and 240 lights are fitted. The buildings have been erected from the designs of Mr. J. M. Brydon, and the Council chamber is to be ventilated by means of an electrically-driven fan. This chamber is adorned with a 50-light electrolier. A part of the building scheme is the erection of technical schools to form the north wing of the Guildhall, but this portion of the structure is not nearly completed.

BELFAST.—The Electric Lighting Committee of the Corporation, at its last meeting, considered an application from the gas company for the supply of electric current to the gas works. Some amusement was caused by the application, which was referred to the Corporation's engineer for report.

BIRMINGHAM.—In response to a letter from the Edinburgh Merchants' Association, the Birmingham Chamber of Commerce has agreed to memorialise the Postmaster-General in favour of the State acquiring the telephone system and carrying it on as a branch of the Post Office.

BLACKBURN.—A scheme for the lighting by electricity of Railway-road and Salford Bridge, which was submitted by the Town Council's electrical engineer, has been referred to the Joint Lamp Sub-Committee to be carried out.

BLACKPOOL.—Messrs. Roger Dawson (Limited) have received an order for supplying the whole of the electric light fittings for the Empire Palace of Varieties now being built in this town.

BOARD OF TRADE REVISED REGULATIONS.—The Hull Corporation have suggested that some of the clauses of these regulations are of a grave and stringent character, and recommend that concerted action be taken by municipal authorities with a view of securing modification of these clauses. Mr. W. H. Brownlee, electrical engineer to the Dundee Council, objects to the leakage current allowed as being too small. The Islington (London) Vestry have referred the regulations to their Electric Lighting Committee, the strongest exception being taken to the clause under which the conduits and receptacles are to be so constructed as to prevent an influx of gas from the adjacent soil. It is pointed out by the Vestry Clerk that the local authorities will be at the mercy of the gas companies, instead of being in the position to require these companies to prevent the escape of gas from their mains into the electric lighting conduits.

BURNLEY.—The lighting of the large clock in the tower of the Town Hall is now effected by electricity; six 16 c.p. incandescents are used to illuminate the four dials and mirror. As it was formerly necessary to leave the gas turned on during the whole of the day, it is expected that a considerable saving will be effected by the use of the electric light.

CHESTER.—At the meeting of the Town Council on Wednesday a report of the Electric Lighting Committee was submitted recommending the Council to authorise the Committee's acceptance of the offer of Thomas Parker (Limited) to supply a complete electric lighting installation for the city for the sum of £14,200, exclusive of building, &c. (estimated at a further £3,000), and to run it for a period of one, two, or three years; to supply public and private lighting at the prices named; and to arrange the terms of the necessary contract and do what might be necessary to have the installation established. This recommendation, it was stated, was made on the advice of Lord Kelvin. Mr. B. C. Roberts, in moving the adoption of the recommendation, said that in delaying so long in carrying out the electric lighting of the city they had lost nothing, but gained a great deal. They had got all the newest improvements, and had also gained other advantages, one of which was that they were to obtain current at so low a price that he hoped they should be able to supply the electric light to the city and the citizens at a comparatively lower price than gas. The Committee's recommendation was adopted.

CLERKENWELL (LONDON).—The new Town Hall, built for the Clerkenwell Vestry from the designs of Mr. Evans Vaughan, is to opened this day (Friday) by Lord Rosebery. The entire building is fitted for the electric light.

COLLIERY PLANT.—Messrs. W. Bassano and Sons, of the Hadenhill Colliery, Old Hill, near Birmingham, have given orders for a complete electric plant to be put down for lighting and hauling purposes at the colliery.

COMMERCIAL PROGRESS.—Mr. Chauncey Depew, a leading American orator and financier, recently delivered an address on the subject of "Commercial Progress," in which frequent reference was made to the important part played by the submarine telegraph cable in the development of commerce and industry. The occasion of the address was the presentation to the Detroit Chamber of Commerce of a painting of Cyrus W. Field. Mr. Depew gave the submarine telegraph cable equal importance with the Crusades and the discovery of America, these three events together, in Mr. Depew's opinion, marking three great eras in the world's history, and were, together with the printing press, responsible for the commercial development of modern times. Commerce had been revolutionised, intelligence widely disseminated, and altogether a wonderful transformation in commercial and industrial intercourse has followed the development of submarine telegraphy.

DOUGLAS.—At a meeting of the Town Commissioners on Monday the draft agreement between the Electric Tramway Company and the Commissioners for the lease of the Douglas Bay Tramway for a further term of 21 years was considered. Several members contended that the Company's offer to pay 15 per cent. upon the gross earnings, and to construct and work a tramway to Upper Douglas was insufficient consideration for the extension of the lease. The agreement was ultimately confirmed by 10 votes to 8.

DURBAN.—The full text of the reports of Mr. W. H. Preece and Mr. H. Fletcher (borough engineer to the Durban Town Council) is issued as a supplement to the *Natal Mercury* of Tuesday, April 23rd. A digest of these reports appeared in our issue of the 31st ult.

DUTCH GUIANA.—After inquiry by a special Commission, it has been decided to adopt electric lighting at Paramaribo, Dutch Guiana.

EDINBURGH.—The Electric Lighting Committee have recommended the Town Council to approve the extension of the electric lighting mains to the Regent, Royal, and Carlton Terraces, to Canongate and the South Side, as suggested by their consulting engineer, Prof. A. B. W. Kennedy. The estimated cost is £3,500.

ELECTRIC LAUNCHES.—Last week was launched, from the shipbuilding yard of Messrs. J. and G. Thomson (Limited), Clyde Bank, the steam yacht "Urania," built for His Excellency Don Francesco Recur, of Madrid. The "Urania" is lighted throughout by electricity, the fittings being specially designed. In addition to powerful lighting plant, a large battery outfit is included. In addition, the "Urania" is provided with an electric launch fitted with batteries of sufficient capacity to allow the launch to travel 100 knots without recharging.

ELECTRIC LIGHTING OF BARRACKS.—In the House of Commons on Tuesday Mr. Campbell-Bannerman stated that no direct comparisons as to improved health from electric light instead of gas had, so far as he was aware, been made, although the advantages of electric light were undoubted. Offers to supply the electric light to barracks had been made, and declined for the present, at Great Yarmouth and Dover. A succession of experiments in electric lighting had been approved, and plans for providing the light in Colchester Hospital and Cambridge lines, Woking, were now in progress.

FULHAM (LONDON, S.W.).—A proposal, made by the Electric Lighting Committee of the Vestry, that a practical electrical engineer be invited to furnish a report on the advisability of introducing the electric light along with the dust destructor scheme, at a fee of 50 guineas, was adjourned for discussion at the next meeting of the Vestry.

GLASGOW.—The Town Council have unanimously adopted a recommendation of a special Sub-committee to increase the salary of Mr. Arnot, the Council's electrical engineer, from £350 to £450 per annum, a condition being that the whole of Mr. Arnot's time be devoted to the duties connected with the Electric Lighting Department.

HALIFAX.—It having been decided by the Governors of the New Infirmary to put down their own plant to supply the Institution with electric light, the Halifax Corporation have decided not to extend the electric lighting mains to the Skircoat district at present.

HARROGATE.—The General Purposes Sub-Committee have invited Mr. Robert Hammond to consult with Mr. Wilkinson, the Town Council's electrical engineer, with a view before carrying out the scheme for electric lighting, which had been adopted by the Council, of having the whole reconsidered as to system, site, and area of supply. Mr. Hammond will shortly report.

HASTINGS.—Extensions of the electric lighting mains of the Hastings Company across London-road into St. Leonards and in several other main thoroughfares of the town have been sanctioned by the local authorities.

HECKMONDWIKE.—Included in a scheme for alterations and additions to the central store premises of the Heckmondwike Co-operative Society is an electric lighting installation throughout the buildings. The cost of the alterations and additions will be £6,700.

HOLBEACH.—At the last meeting of the District Council, tenders were considered for lighting the district. Amongst the tenders was one from Mr. F. Barton, of Blackburn, through his agent, Mr. Bean, of Holbeach, to light the streets by electricity for £210 per annum for a term of seven years. This represented a difference of £50 in favour of gas lighting, which was ultimately selected.

Digitized by Google

HULL.—The Corporation have received a notification from the Local Government Board, sanctioning the borrowing of a further £2,800 for electric lighting purposes, and it has been decided to apply for sanction to borrow another £8,000 for additional plant, which is almost immediately required.

INCORPORATED GAS INSTITUTE.—The thirty-second annual meeting of this Institute was opened at Edinburgh on Tuesday, and Lord Provost M'Donald, in tendering a hearty welcome to the members, said that in Edinburgh they had recently spent something like £125,000 upon their electric undertaking. He was of opinion, however, that in large cities the introduction of electric supply stations would not affect the consumption of gas in any marked degree. The Lord Provost, however, omitted to point out that in almost all cases where the electric light has been introduced a considerable reduction in the price of gas has resulted, and unless this policy is adopted by the gas companies to a larger extent the electric light will, in the near future, prove a much more serious competitor. The Institute's third prize was awarded to Mr. William Chew, of Blackburn, for his Paper read at last year's meeting on "Gas and the Electricity Supply of Blackpool."

IPSWICH.—A report of the Electric Lighting Committee of the Town Council was discussed at a special meeting last week, and was ultimately adopted. It recommends that the question of electric lighting be shelved for the present. In commenting upon this decision the *East Anglian Daily Times* calls attention to the fact that the proposal to adopt the electric light at Ipswich was first brought forward as a question of private enterprise. A resolution was carried at a Town Council meeting to allow a company to obtain a Provisional Order. This resolution was practically rescinded by similar powers being given to a competing company. In April, 1894, it was resolved by the Council to forthwith apply for a Provisional Order. Since this date, however, no steps have been taken to carry out the resolution. The arrangements with the Gas Company have not hitherto been altogether satisfactory, and, as a new bargain has shortly to be struck, the town is not likely to benefit by the action of the Council in shelving the electric lighting question.

KINGSTOWN (IRELAND).—It is stated that a new company, to be called the Electricity Supply Corporation of Ireland (Limited), is in course of formation, and has applied to the Kingstown Commissioners for their approval of an intended application to the Board of Trade for a Provisional Order to light the town and district by electricity.

KINGSWOOD (BRISTOL).—Efforts are being made to get the electric tramway extended to Warmley Hill. It is likely that this and other extensions will be incorporated in a Bill to be introduced in the next session of Parliament.

MADRAS.—It was originally intended to adopt the overhead system for the Madras electric tramways; but, as it was considered probable that difficulties might arise in connection with the local telegraph and telephone services, it was decided to substitute the conduit system for section No. 1 of the tramways. It has, however, been definitely arranged that in sections 2 and 3 the overhead system will be used. It is, moreover, possible that section No. 1 will be ultimately worked on the overhead system.

MAZARRON.—A central electric supply station has recently been erected at Mazarron, a large mining town in the Province of Murcia, Spain, and the first set of plant is erected and in working order. This consists of a 20 H.P. nominal Robey engine, and a 37-kilowatt Mordey-Victoria alternator, giving 2,000 volts at 650 revolutions. This is excited by a 30-ampere Royce shunt-wound dynamo. Steam is supplied by a 20 H.P. Robey locomotive boiler. The principal thoroughfares of the town are to be lighted by 16 c.p. incandescents, in series, at 2,000 volts, and the mines and private buildings are supplied with current from secondary mains at 110 volts. It is anticipated that two similar sets of plant will shortly be put down.

MELROSE (SCOTLAND).—The price of gas at Melrose is 5s. 7½d. per thousand, which Messrs. Parr and Gillies think justifies them in offering to light the borough with electricity, providing a demand for 1,000 16-c.p. lights is guaranteed.

MORECAMBE.—At the meeting of the District Council on Monday the Sub-Committee appointed to negotiate for the purchase of the local Electric Light and Power Company's undertaking reported the terms offered by the Company, and it was decided to employ an expert to inspect and advise the Council in the matter.

OLDHAM.—In moving the acceptance of the minutes of the Electric Lighting Committee, which were given in our last issue, Mr. Alderman Smith entered into details concerning the proposed extensions. The Committee recommend the purchase of two second-hand engines of 200 H.P. each, and dynamos, which would effect a saving of £1,000 over their estimate for new plant. The minutes were adopted.

OLYMPIA.—Messrs. Rowland, Barnett and Co., who have installed a private gas-driven electric light plant at Olympia, have sent us a table and other particulars of a set of tests made on this plant by Mr. T. Hanning for the Directors of Olympia. In actual work the combined plant is at full load during the whole time it is running; but in the tests its capacity and economy at varying loads have been measured. A combined efficiency of 69 per cent. is given at full load, a figure which is highly creditable, and the efficiency of the dynamo alone was found to be 92 per cent. At 25 B.H.P (full load) 26·4 cubic ft. of gas per brake horse-power was consumed, a useful electrical output of 638·4 watts per brake horse-power being obtained. The price paid for gas is 1s. 8d. per 1,000 cubic ft. There is a margin of about 7 H.P. in the capacity of the plant, and when the engine was run up to this limit, 38 H.P., the consumption stood at 24 cubic ft. per brake horse-power per hour.

RATHMINES.—At the last meeting of the Town Commissioners Mr. Hewson called attention to the subject of the electric tramways. He pointed out that the Commissioners had been supplied with a photograph which gave an exaggerated idea of the appearance of the overhead wires for an electric tramway system, and that the only effect of such a photograph would be that opposition would be advanced against the overhead system of electric tramways. It was pointed out that the Committee have unanimously adopted the resolution of opposing the Bill authorising the erection of the electric tramways unless an underground system is adopted by the Tramway Company.

SOUTHPORT.—A proposal to adopt the Brighton method of charging for electric current was under discussion at the last meeting of the Town Council on the initiation of the Chairman of the Electricity Committee, Councillor Esford, but no decision was arrived at. The introduction of the electric light into this district has already resulted in a reduction of the price of gas by 3d. per 1,000.

STAFFORD.—Considerable extensions of the electric lighting mains have been decided upon by the Town Council, the district chosen being Victoria-square, Foregate-street, and Newport and Lichfield-roads.

STRIKE AT PONDERS' END.—Last week a large number of the employés at the Ponders' End Works of the Edison and Swan United Company came out on strike, and the Company lost no time in declaring a lock-out, and unless the strikers speedily return to their work the Company threaten to send a large portion of their work to Germany. The question in dispute is, we understand, chiefly the rate of wages paid. It is unfortunate that the workers are not allowed to settle their dispute with the Company direct. The present dispute seems eminently one to be amicably settled by the parties immediately concerned.

SUNDERLAND.—A considerable extension of the electric lighting mains to the south-west part of the borough is in contemplation by the Corporation in response to the numerous applications received.

SYDNEY (N.S.W.).—It is not only in the Old Country that local authorities act the dog in the manger. Complaint is freely made of the action of the Sydney City Council in opposing the application of a local company for powers to supply the city with the electric light. About two years ago two Bills were before the Sydney Parliament for lighting the city electrically, one promoted by the local gas company and the other by a private electric lighting undertaking. The Sydney public were hostile to the application of the gas company, and the City Council effectually extinguished any chance the private company may have had of obtaining a Bill by themselves applying for powers to supply electric current. These powers were readily granted by Parliament, but, so far, no further steps have been taken by the Council to introduce the light, notwithstanding that evidence is forthcoming that a considerable demand would result from any well-considered scheme promoted by the local authorities.

TAUNTON.—Prof. J. A. Fleming's report to the Town Council states that the result of his thorough inspection of the electric lighting station, and of the new work carried out during the past year in connection with the establishment of the second transformer sub-station, is to show that everything is in good working order, and the whole of the plant carefully supervised.

THURMASTON (LEICESTERSHIRE).—The District Council are considering the advisability of lighting the district electrically at an estimated cost for street lighting of £1,000 and annual working maintenance of £189. The cost of an installation for private lighting on a 500-light basis has been given as £2,000, with an annual upkeep cost of £331. Gas in the district is 4s. 2d. per thousand.

TORQUAY.—During the inquiry held by Col. Luard into the application of the Corporation for powers to borrow £3,250 for the purpose of a refuse destructor at Upton, it was stated that a portion of the ground would probably be utilised as a sub-station for the supply of electric current. The Town Council have received a notification from the Board of Trade offering to extend the powers of the Council under their electric lighting Provisional

Digitized by Google

Order for another twelve months, but intimating that no further extension will be granted.

WALLASEY.—The Ferry Committee of the District Council are arranging for the introduction of the electric light at Seacombe.

WEYBRIDGE.—A proposal was made at the last meeting of the Urban District Council that the tender of the Weybridge Electric Supply Company, for lighting the district by electricity, should receive the approval of the Council. Mr. Ward opposed this course being taken, and strongly recommended that the Council should themselves possess the electric lighting undertaking. After some discussion a resolution that the matter be referred back to the Highways and Lighting Committee for further consideration was carried.

WIGAN.—Some doubts having been expressed by members of the City Council as to whether it was likely that progress would be made with the electric lighting scheme, Mr. Holmes, Chairman of the Gas and Electric Lighting Committee, said that several meetings had been held, but up to the present the members were not quite agreed as to the carrying out of the scheme. His personal idea was that if they were to have the electric lighting they should be moving, or that the matter should be definitively shelved.

YARMOUTH.—Col. Hasted held a Local Government Board Inquiry at the Town Hall last week into the application of the Town Council for powers to borrow a further sum of £17,500 for electric lighting purposes. Mr. A. H. Preece, on behalf of Mr. W. H. Preece, consulting electrician to the Town Council, explained that the number of lights already installed was equal to the full power of the existing working plant, and as applications were coming in daily an extension was absolutely necessary. The Borough Surveyor said an immediate expenditure of £1,600 was necessary, and the remainder would be spent as required. No opposition was offered to the scheme. The Surveyor's report of the last meeting of the Town Council stated that 4,530 lamps are now connected or on order, from 87 consumers. The consumption of current shows a steady increase. A letter was received from Mr. Preece that the new dynamo would cost £1,346, the oil feeding apparatus £60, and the building works £100, increasing the estimate of £1,400. In view of the extended demand for the light the Surveyor was directed to get the work done as quickly as possible. Complaint is made that an offer of the local gas company to fix incandescent gas lights in several of the principal thoroughfares of the town has been too hastily accepted, it being pointed out that the Council have new plant and every necessary for lighting these thoroughfares by electricity from their own supply stations. The gas company's offer has been accepted for three years.

YORK.—At the meeting of the City Council, on Monday, on the presentation of the report of the Watch Committee, Mr. Ald. Rymer complained of the increased cost of the lighting of the police station and new public buildings, which he stated to be very much in excess of the late gas lighting cost. "The electric light was an expensive toy, which would be exploded by new improvements in gas lighting, and the Council would live to regret that they had never put gas in the new police station." In reply, Mr. Ald. Wragge pointed out that as the new police and fire brigade buildings had been considerably extended it was not surprising that a larger number of lights and better light was required. It was no use for Ald. Rymer to move dilatory resolutions in favour of keeping the electric light from the city. They must have the light, and they ought to have it speedily. The present state of things was a standing disgrace.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

WOODHOUSE AND RAWSON UNITED, LIMITED (In Liquidation).

By the direction of Mr. Justice Vaughan Williams, a largely attended meeting of Five and a-Half, Six, and Ten per Cent. Debenture-holders of this Company was held yesterday, at the Cannon-street Hotel, London, "for the purpose of considering and, if thought advisable, of authorising the employment of the funds of the debenture-holders upon legal proceedings against the Directors and auditors of the Company by the Official Receiver and Liquidator for recovery of moneys which counsel have advised that such Directors and auditors are liable to refund." The notice calling the meeting added that Mr. Justice Vaughan Williams had further directed that there should be one meeting for all classes of debenture-holders, but, if necessary, a vote of each class should be separately taken.

Mr. C. J. STEWART (the Official Receiver and Liquidator) occupied the chair, and reviewed the history of the Company and read the opinion of counsel to the effect that the Board of Directors were distinctly liable in regard to the dividend paid upon the balance sheet of 1891, they contending that £20,000 had been paid out of capital. The total ultimate loss that they might anticipate for all the debenture-holders and shareholders could not be taken at less than £500,000. He asked the meeting to put aside any vindictive feeling, and to decide in a dry commercial sense whether they would take this action for restitution or not.

After considerable discussion,

Mr. A. BOND, representing the Ten per Cent. Bondholders, spoke strongly against proceedings against the Directors, as he failed to see the advantage to accrue to that class of debenture-holders.

In reply to questions, the CHAIRMAN said that the cost that would be involved in going to law upon the matter would be about £2,000 on each side.

Mr. BACON strongly criticised the action of the Directors during the history of the Company, and said that he came to that meeting with the idea of pushing action to the uttermost against those Directors. He dealt with what the committee that was appointed before the Ten per Cent. Debentures were issued did in the interests of the Company. He said that he was a member of that committee, and he was now in accord with Mr. Bond that the Ten per Cent. Bondholders had nothing to do with taking action against the Directors, although he fully admitted that the Directors were deserving of the worst punishment that could be meted out to them. The action to be taken would rest, therefore, in the hands of the other classes of debenture-holders.

Mr. PILLING and other debenture-holders addressed the meeting, and expressed the opinion that those who were to blame for letting the shareholders into this trouble had made themselves pretty well secure. He strongly urged that the opinion of counsel should be acted upon. He failed to see where any doubt could be cast upon such an opinion as that of Mr. George Farwell, Q.C., and Mr. Howard Wright. He (the speaker) represented Five and a-Half and Six per Cent. Debenture-holders, and he would vote emphatically for prosecution.

Mr. SAMUEL POPE, Q.C., one of the late Directors, characterised the action of Mr. Pilling at the time of the public examination as showing animosity. He (the speaker) denied any criminal guilt, but they might be able from the action he had taken in good faith in connection with the Company to force him into the Bankruptcy Court. If he had done wrong he was ready to make restitution to the last farthing. He already stood to a loss of £10,000, and what more they could force further out of him he did not know. They could take the case to the House of Lords, and he would still defend himself; but what would be left to him when the case came out of the Lords he was perfectly unable to say.

The CHAIRMAN, in reply, said that he feared there was no likelihood of the amount referred to in the opinion of counsel (£20,000) being divided, if it were gained, amongst the Five and a-Half per Cent. Debenture-holders.

Mr. JONES asked whether the Five and a-Half per Cent. Debenture-holders had only the chance of individual action. They were all Six per Cent. Debenture-holders at one time, and they were led to believe that the whole of the Six per Cent. Debentures were to be converted. They ought to have a meeting called of the Five and a-Half per Cent. Debenture-holders to consider how they became Five a-Half per Cent. Debenture-holders.

The CHAIRMAN said that was the case, the Five and a-Half per Cent. Debenture-holders only had individual action.

Mr. MATHESON said that he had investigated that matter for the Receiver, and the reason there were both Five and a-Half and Six per Cent. Debenture-holders was that the whole of the Six per Cent. holders did not choose to convert. To win the action against the Board they must prove dishonest intent. (No, no.)

The CHAIRMAN: No, no.

Mr. MATHESON said that, as representing Mr. Wood, the plaintiff in the action and holder of £2,000 of Six per Cent. Debentures, he would vote against taking any proceedings.

Mr. PAYNE said he was instructed by the largest but one Six per cent. Debenture-holder to say that he was strongly opposed to the taking of any action.

The CHAIRMAN, in response to a suggestion of Mr. Fladgate, proposed that the meeting of the Five and a-Half per Cent. Debenture-holders should be adjourned, and the voting of the Six per Cent. and Ten per Cent. Bondholders should be conveyed to them later.

The general feeling of the Five and a-Half per cent. Debenture-holders was in favour of the proposal.

The CHAIRMAN thought that there could be no legal objection to an adjournment. He only proposed an adjournment of only a few days for the Five and a-Half per Cent. Debenture-holders' meeting.

Mr. TURNER referred to the Hansard case, and asked whether it was not true that, though a large sum was recovered, it was compromised, and a very little got into the hands of the unfortunate sufferers?

The CHAIRMAN said there were civil proceedings in the Hansard case, and that a considerable sum was very rapidly recovered. He then put the question of the adjournment of the meeting of Five and a-Half per Cent. Debenture-holders to that section of those present, and declared that 26 voted for it and 26 against, and he then gave a casting vote in favour of the adjournment.

The question of taking proceedings against the Directors was then put to the Ten per Cent. Debenture-holders, and unanimously rejected.

The Six per Cent. Debenture-holders then voted, and on a show of hands, there were four hands for proceedings and about a dozen against.

The meeting of the Five and a-Half per Cent. Debenture-holders was then adjourned till Wednesday next, 19th inst., at 33, Carey-street, Lincoln's Inn-fields, W.C.

A vote of thanks to the Chairman closed the proceedings, which had lasted close upon two hours.

COMPANIES' MEETINGS.

West Coast of America Telegraph Company (Limited).

The eighteenth ordinary general meeting of this Company was held on Tuesday at 50, Old Broad-street, Mr. J. Denison Pender in the chair.

The SECRETARY (Mr. Fred. L. Robinson) read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN then said: In moving the adoption of the report and accounts, I will just put you in possession of some of the facts and particulars relating to the Company. They are not very bright, I am sorry to say; but the best that can be said about our affairs is that they are certainly brighter than they were when I met you this time last year. The traffic receipts show an increase of £8,057 as compared with those of the previous year, and the interest account a decrease of £1,401. This is owing to our having to use by degrees our reserve fund, which, of course, is not now bringing us in anything like what it did some time ago. Our gross receipts were £6,657 in excess of those of 1893. The revenue derived from the line of the Pacific and European Telegraph Company is very satisfactory. As you are aware, this line was opened to the public on March 19, 1894, and since the opening we have by degrees gained the confidence of merchants and shippers trading with Chili and Peru. This has only been done by giving a thoroughly efficient service, and we now have a fair share—a good share I might say—of the traffic. This, has been a gradual process, as you may imagine, after our competitors had been in possession of the entire traffic for two years, but so much has been done, and we hope to keep what we have got and to increase the number of our customers. It would not be politic to give you details as to the amount of this traffic, or its value to us, as any such statement would be giving too much information to others, who are not interested in our welfare. The local traffic for 1894 exceeded that of the previous year by over a quarter of a million words, but what we have gained in traffic we have lost in exchange: the average rate was 12d., as against 14d. in 1893. The fluctuation in the rates of exchange entirely upset any calculation as to the sterling value of this class of traffic, the rates being collected in currency, and so many of our expenses, particularly salaries, being paid in sterling. We may reasonably expect that we shall not in future be much troubled with these fluctuations, as the paper currency of Chili is now replaced by gold, for the first time in 17 years, on a basis of 18d. to the dollar, and the exchange will not greatly fluctuate from that figure. The rate of exchange at the present time is 17¹⁄₈d. Our gross expenditure for 1894 shows an increase of £521. 8s. 5d. as compared with 1893, the cost of maintaining our cables and land-lines being largely responsible for the increase. With regard to the cost of maintenance, this is naturally a varying amount, and dependent entirely upon the number of breakages to our cables and the time occupied in effecting the necessary repairs. The ship we keep out there has certain standing charges in connection with it, but we do not keep the crew on board all the time, and when any break takes place the cost of the vessel is naturally greatly increased, not only on account of the extra crew that has to be taken on board but on account of the coal consumed by the

Digitized by Google

vessel for her journeys, which, as a rule, are pretty long ones up and down the coast. We had two cables interrupted last year—the Caldera-Serena section and the Valparaiso-Talcahuano. The former fault was caused by the rocky nature of the bottom over which the cable was laid, and in this case the line of cable was diverted to a better bottom, after a delay of 12 days, owing to bad weather: the latter fault was caused by a submarine disturbance. The Chorillos shore end at the northern termination of our system was renewed. It is worthy of notice that the original shore end had not been disturbed since it was first laid—a period of 19 years. A new station was opened on December 31st last at Coronel, a port of call and coaling station a little to the south of the city of Concepcion, and connected with our Talcahuano cable by a land line. This addition to our system acts as a feeder, not to a great extent certainly, but it is a paying connection, and may become of more value hereafter if trade out there improves. These, I think, are all the particulars which I have to bring forward, without going too closely into the details of the traffic, as such information would go into the hands of people who are competing against us, and taking every opportunity they can of making use of anything we say or do. There is one circumstance which I may mention to you which will show you how really efficient the line is. We endeavoured the other day, with a piece of news which has been used before with a similar object, to see how quickly a message could be sent over the line. The Derby, in which all parts of the world, whether English or foreign, seem to take an interest, was won the other day, I believe, at 25 minutes past 3 o'clock, and that news was up in our office at Valparaiso at 28 minutes past 3. It therefore took only three minutes to get from Epsom to Valparaiso. You will see, by looking at the map, that this message had to go from Epsom to London, London to Porthcurnow, from Porthcurnow to Lisbon, from Lisbon to St. Vincent, from St. Vincent to Pernambuco, from Pernambuco down the coast to Buenos Ayres, and then over the Pacific and European Company's line to Valparaiso. I therefore think that this was one of the smartest pieces of telegraph work which has ever been carried out; but what makes it so pleasing, especially to myself, is that I have a great deal to do with the Eastern Company, of which I am the Managing Director, and I am also a Director of the Brazilian Company; and the fact I have mentioned shows that the staff right throughout must be very efficient. As to the outlook, I am not going to prophesy. It is quite impossible for us to speak with any degree of confidence, so much depends upon circumstances beyond our control. Up to the present time it looks as if during the year upon which we have now entered, we shall at least be able to pay our expenses and debenture interest without having to encroach again upon our reserve fund, which has become very low; the greater portion of it is invested in cable, and I am sorry to say, therefore, that it is not in securities available at any moment. Looking further ahead, we continue hopeful as to the future of the Company, and the shareholders may rest assured that everything possible is being done. When I tell you that we are now, I hope, paying our working expenses and our debenture interest, you may say that that is not very much; but, remember, when I came before you last year we were not doing anything like that. We have got to obtain this traffic from the Central and South American Company, who have held it before we were able to carry it. They have had a free hand for two years, and we have to get the traffic back. I can only tell you that there is a large increase in the traffic, and I think there may perhaps be enough for both of us if we but act perfectly fair to each other. I do not see why we should cut each other's throats. We are getting this traffic steadily, and I believe that it is through the very efficient way in which it is being carried. I shall be glad to answer any question, so long as it is not prejudicial to the interests of the Company, and to give any further information that may be asked from me. I now move—

"*That the report and accounts for the year ending December 31, 1894, now presented, be received and adopted.*"

Mr. FREDERICK WALTERS seconded the motion, which was carried unanimously.

The CHAIRMAN: Since the death of Mr. Roberts there have only been two Directors of the Company. I do not think it is any use adding to the number, and the Company derive a certain benefit by the fees of the third Director going into its coffers. It is not worth while to alter the Articles of Association so as to make one Director retire instead of two, as at present.

Mr. J. Denison Pender and Mr. Fred. Walters having been severally re-elected to their seats at the Board.

Mr. LAMONT proposed the re-election of the auditor, Mr. J. F. Clarke. Incidentally, the speaker expressed satisfaction at the statement of the Chairman that the traffic of the present year was likely to cover all the expenses and liabilities of carrying on the concern. He only trusted that the Chairman's hopes would be fulfilled, and exceeded.

Mr. FROST seconded the motion, which was unanimously carried.

The CHAIRMAN: In regard to the few words which have fallen from Mr. Lamont, I wish it to be thoroughly understood that I believe at the present time, as near as we can get the figures, that the Company is paying its debenture interest and working expenses. The traffic, however, may fall off, and we may not be doing so well some months hence, so I do not want it brought up against me in future that I made a statement which was not accurate.

Mr. PACE then proposed a vote of thanks to the Chairman and Directors, who, he said, were working an uphill business with great care. The fact of there being only two Directors meant that those gentlemen must do rather more work.

The motion was seconded and carried unanimously.

The CHAIRMAN: I beg to thank you on behalf of Mr. Walters and myself for your kind expressions. If you will allow me I will include the staff in this vote, because it is always satisfactory to those who are working hard in the London office and at the other end of the world to have their services appreciated. They are, I believe, doing their very best, and working very keenly to bring this Company into the position it held a few years ago.

Hobart Electric Tramway Company (Limited).

The second annual meeting of the shareholders of this Company was held at the offices, College Hill Chambers, Cannon-street, E.C., on Tuesday, under the presidency of Dr. Alfred Mattei.

Mr. G. CARNABY HARROWER (the Manager) read the notice calling the meeting, and the Directors' report was taken as read.

The CHAIRMAN said: Gentlemen, you have already received a copy of the report and balance sheet, and from it you will have seen the good work we have done. We have carried 2,478,938 passengers, and we have run 584,117 car miles, and our latest report from our Manager shows that for the month of April we have reduced the working cost to 6½d. per car mile. This is our first revenue account, and I wish to make a few remarks. Taking the revenue account for the year ended December 31st last, we think the items of £5,759 for wages and £1,042 for fuel too high. We have written to our local committee in Hobart, and to our able Manager there, Mr. A. C. Parker, to reduce these items consistently with the due efficiency of the service. I have reason to believe that we shall succeed in reducing these items. We all agree that the administration expenses, including Directors' fees and office expenses, are too high. We are doing our best to reduce these charges. Cables and law charges amounting to over £100 are an expense which, though necessary at the beginning, should now be considerably curtailed. Our local committee object to the payment of income tax, at all events on their fees, and we shall try to arrange this. The standing item of £2,500 per annum being 5 per cent. on the £30,000 First Mortgage Debentures, and 5 per cent. on the £20,000 Second Mortgage Debentures, cannot, of course, be reduced. There is one item which I am glad to say we shall not see again in our accounts, and that is the large amount payable to Messrs. Siemens Bros. and Co. (Limited) for working the line. It would be not only ungracious but unjust if I did not, on behalf of myself and my colleagues, express our gratitude for the generous support that Messrs. Siemens Bros. and Co. have given to us in every possible way. Indeed, I wish again to testify to the satisfactory manner in which they have performed their contract. I am glad to say that we are doing the work ourselves cheaper, for we paid Messrs. Siemens Bros. and Co. £1,000 per month, and we are doing it for less, as it is natural we should, having a committee of local gentlemen and a local manager on the spot. The revenue, taking everything into consideration, is satisfactory. Tasmania, in common with the rest of Australia, has gone through a great crisis. We have, of course, suffered like the rest. Since opening the line we have carried a very large number of passengers indeed. We are told that our permanent way might be more satisfactory, and this matter continues to have our constant attention. The cars have not been used in their full number, two of them having been damaged. At the same time I am glad to be able to say that we are fully equipped to do the service which we are called upon to do. As to the capital account, we have taken powers from the shareholders and from the holders of the Second Mortgage Bonds to increase the issue of Second Mortgage Bonds by £5,000, and these bonds now stand at the total amount of £20,000, and there are £30,000 of First Mortgage Bonds, making a total of £50,000. With this £5,000 we have settled the liability of Messrs. Siemens Bros. and Co. of £3,400 and the vendors £500, leaving in our hands a small balance of authorised but unissued Second Mortgage Bonds. I am glad to say that our Hobart letters advise us that they had out of revenue paid off the bank overdraft of £295 and the £1,286 for outstanding accounts in Hobart, so that our next balance sheet will compare very favourably with this one, except as to the increased amount of Second Mortgage Bonds. On the other hand, you will remark that we are having a car shed constructed, which, according to latest advices, should now be completed. We have not forgotten the lighting of Hobart by electricity, but I regret to say that I am not now able to say more upon this subject than that we stand in an exceptionally favourable position with regard to that matter. My friend Sir Edward Braddon, the Premier of Tasmania, writes to me that our tramway has become not only popular with the Hobart people, but a municipal necessity, and nobody would now dare to interfere with it. This is very reassuring, coming, as it does, from such a source. I am able to say that we were most fortunate to have secured the services of Sir E. Braddon, and of Messrs. Barclay, Syme and Grant, to act as a local committee, for there is no doubt that it is due to them that so many of the difficulties which are always met with in an enterprise of this kind—with the Government, with the Telegraphic Department, and with the Municipality—were overcome, and in Mr. Parker the Board feel they have a gentleman in whom they can place the utmost confidence for the successful working of the line. In conclusion, I think the bondholders, especially the holders of the First Mortgage Bonds, have ample evidence from the result of this year's working to feel satisfied that they have a well-secured 5 per cent. bond, and if all the assurances we receive from Tasmania are verified, the shareholders in the immediate future will have no cause for regret at having invested their money in this enterprise. I beg to move the adoption of the report and accounts.

Mr. D. J. MACKAY seconded the resolution, and after a brief discussion the report was adopted.

Mr. J. G. BELLAMY was re-elected a Director of the Company, and Messrs. G. N. Read, Son and Co. were reappointed auditors.

The usual vote of thanks to the Chairman and Directors closed the proceedings.

NEWCOMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1895, pages *304-332, &c. &c.*]

REFLECTOR SYNDICATE (LIMITED).—This Company has been registered with a capital of £2,000, in £1 shares, to carry on business as manufacturers of and dealers in all kinds of reflectors and projectors. The first Directors are Sir B. W. Walker, Bart. (or some one nominated by him), L. W. N. Hickley, and H. H. Hosack.

RENNY, FORBES AND CO. (LIMITED).—This Company has been registered with a capital of £2,000, in £5 shares, to enter into an agreement with Messrs. R. H. A. Atkin and W. A. Wade for acquiring the business of chemical manufacturers, &c., hitherto carried on by Renny, Forbes and Co. at Alperton, Harrow, Middlesex.

CONNOLLY BROTHERS (LIMITED).—This Company was registered on June 1st with a capital of £20,000, in £5 shares, to acquire and take over as a going concern the business of insulated cable manufacturers and electricians carried on at the Blackley Vale Mills, Blackley, Lancs., by John T. Connolly and James Connolly, under the style or firm of "Connolly Brothers," and to enter into and carry into effect an agreement to be made between the said vendors and the Company, and to carry on the business of manufacturers of and dealers in insulated and other wires and cables for use for telegraphic, telephonic, electric lighting and other purposes, electricians, engineers, merchants, bankers, shippers, manufacturers, contractors, &c. The subscribers are:—

	Shares.
John T. Connolly, Vale Mills, Blackley	1
James Connolly, Vale Mills, Blackley	1
Thomas Connolly, Eastwood, Clayton Bridge	1
Louis Frankenstein, 33, Miller-street, Manchester	1
Mrs. E. Connolly, Eastwood, Clayton Bridge	1
William Connolly, Eastwood, Clayton Bridge	1
Joseph H. Peters, 62, King-street, Manchester	1

The first Directors are John T. Connolly and James Connolly, who are to be the Governing and Managing Directors, and to hold office until 1899.

FAREHAM ELECTRIC COMPANY (LIMITED).—The annual return to April 16th has been filed. The nominal capital is £5,000, in £1 shares, of which 4,158 have been allotted. The full amount has been called upon each.

GLOBE ELECTRIC COMPANY (LIMITED).—The annual returns to March 15, 1894, and March 14, 1895, were filed on May 27th. In each case 5,607 shares were taken up out of the nominal capital of £10,000, in £1 shares; of these 5,500 have been issued as fully paid to Sir William Vavasour, Bart. The full amount has been called and paid on the remaining 107 shares.

HOPE-JONES ELECTRIC ORGAN COMPANY (LIMITED).—The annual return to October 31, 1894, was filed on May 22nd. The nominal capital of £25,000 is divided into 1,200 "A" and 1,300 "B" shares of £10 each, and all the latter have been taken up, and are considered as fully paid; 765 of the former class have been subscribed for and allotted, upon which £7,640 has been paid.

HOVE ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return to March 25th has been filed. The nominal capital is £40,000, in shares of £5 each; 5,049 have been taken up, and the full amount per share has been called on 4,502, while calls amounting to £2 per share have been made on the remaining 547; £23,614 have been paid (which include the sum of £480 received in advance of calls), leaving £170 unpaid.

CITY NOTES.

AMERICAN BELL TELEPHONE COMPANY.—The usual quarterly dividend of 3 per cent. has been declared, with 1½ per cent. bonus extra.

CHATHAM, ROCHESTER, AND DISTRICT ELECTRIC LIGHTING COMPANY (LIMITED).—An adjourned annual meeting of this Company was held last week, Mr. H. Jasper, the Chairman of the Company, presiding. For the second time no quorum of members was obtainable. The Chairman remarked that they could not submit and adopt the report by resolution, as there was not a sufficient number of shareholders present. They might, however, declare the dividend as recommended, and this was agreed to. In reply to several questions the Chairman said he was sorry they had not more customers, but the public had not taken the light so extensively as was hoped. They had two new engines, one of which was erected and in use, and the other would shortly be ready. They had lost two of their largest customers, and this had reduced their profit. These two were supplying their own light. The price the Company were now charging, when compared with gas, showed an equivalent of gas at 1s. 11d. per 1,000. The Directors' report states that the profit of the year ended December 31st last was £456. 13s. 6d. As there is every indication that the Company will earn greater profits, the Directors propose to pay a dividend of 2½ per cent. out of the net profits earned, carrying forward £396. 6s. 5d. The arc lamp plant will be completed shortly, and numerous customers are desirous of using these lamps. It is proposed to sell the current for these lamps at a rate which is the lowest in the kingdom out of the coal districts; but the Directors nevertheless anticipate from their extremely low working expenses a fair amount of additional profit.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this railway for the week ended June 9th were £904, as against £911 in the corresponding period of 1894, being a decrease of £7. The total receipts for the half-year amount to £21,437, against £20,924, an increase of £513.

COMMERCIAL CABLE COMPANY.—The management of this Company has declared the usual quarterly dividend of 1¾ per cent., payable on July 1st next. The transfer books will be closed from June 21st till July 2nd.

ELECTRIC AND GENERAL INVESTMENT COMPANY (LIMITED).—For the purposes of preparing the dividend warrants, the transfer books and register of members of the Company will be closed June 19th to July 2nd inclusive. The Directors have decided to recommend the payment of a further dividend on the capital paid up on the Ordinary shares at the rate of 30 per cent. per annum for the six months ended 31st May last, making, with the interim dividend already paid, a total of 20 per cent. for the year, and also to make a distribution of £35. 16s. on each Founder's share for the year.

ELECTRIC CONSTRUCTION COMPANY (LIMITED).—The numbers are issued of 10 debentures of £100 each, one debenture of £50, and 120 debentures of £10 each of the Six per Cent. Second Mortgage Debentures of this Company, which were drawn on the 7th inst. for payment on July 1st next.

ELMORE'S GERMAN AND AUSTRO-HUNGARIAN METAL COMPANY (LIMITED).—The fourth annual meeting of this Company was held at Winchester House, London, on Wednesday, Mr. MacFarlan presiding. The Chairman said, as to the present position and progress of the Company, he was glad to say that from January 1st to June 8th—that was to Saturday last—the weight of goods sold amounted to 63½ tons, as against 22 tons for the same period last year. Although the price of copper had been low—in fact, the lowest on record—their prices remained high, averaging £98 to £100 per ton. The Company's products had won their way into the esteem of consumers, as was exemplified by the fact that during the 23 weeks ended Saturday last 397 orders were received, against 579 orders during the whole of last year, and their customers had increased from 243 on December 31st last to 309 on the 8th inst. As many as 71 orders had been received from one customer—a fact which gave them hope for the future. The Company had introduced a new article, made by the Elmore process, which was likely to monopolise the market—a copper condenser cover for torpedo boats, and several of these had been supplied to Government contractors in Germany. Their new plant was giving great satisfaction, and a considerable sum had been expended in altering and improving the old plant. They hoped to be able to put down a further 16 tanks—equalling four tons a week—before the end of the present year. The Directors were satisfied that the concern was likely to prove a valuable property. They had been approached in two or three different directions by capitalists offering to find large sums of money for filling the factory with plant, and for the purposes of the Company generally.—Mr. Peters pointed out that the same plausible statements had been made that day as for three years past, and none of the hopes held out had been fulfilled. They had a paid-up capital of something like £230,000, and the chief asset of value was patents, £215,000. Considering the results achieved, he should like to know what these patents were really worth. He thought the best thing would be to wind up.—The report and accounts were, in the end, adopted.

GREAT NORTHERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of May were £28,400. The receipts from January 1st to May 31st were £124,000, and in the corresponding months of 1894 and 1893 £105,800 and £108,000 respectively.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended the 9th inst. amounted to £1,671. The amount for the corresponding week last year was £843. Increase, £828.

THE METROPOLITAN ELECTRIC SUPPLY COMPANY (LIMITED).—This Company announces the payment on July 1st of interest for the half-year ended June 30th on the Four and a-Half per Cent. First Mortgage Debenture Stock, and the transfer books will be closed from the 17th to the 30th inst. inclusive.

NATIONAL TELEPHONE COMPANY (LIMITED).—The transfer books of the Three and a-Half per Cent. Debenture Stock of this Company are announced to be closed from the 17th to the 29th inst. inclusive for the purpose of preparing the interest warrants due July 1st.

PHONOPORE COMPANY (LIMITED).—The transfer register of this Company is closed from June 13th to 27th inclusive. A meeting of shareholders was held yesterday (Thursday) at Winchester House, London, E.C.

TELEGRAPH MANUFACTURING COMPANY (LIMITED).—The annual ordinary general meeting of the proprietors of this Company was held last week, when it was decided to distribute as usual a dividend of 5 per cent., and in addition a bonus of 2½ per cent., both free of income tax.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended June 7th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,650.

WESTERN UNION TELEGRAPH COMPANY.—It is announced that the Directors of this Company have declared a quarterly dividend of 1¼ per cent.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 892. [No. 8. Vol. XXXV.] FRIDAY, JUNE 21, 1895. PRICE SIXPENCE.

NOTES.

It not unfrequently happens that when the din and dust of a lengthy scientific discussion subside the painstaking, persevering individuals who have endeavoured to follow the varying fortunes of the verbal battle are left to draw their own conclusions, and as often as not, are quite unable to draw any definite conclusion whatsoever from the maze of conflicting assertions. Whether this was the unhappy state of any of our readers at the termination of the great "Sine Wave Controversy," which we light-heartedly set in motion one day last summer, or whether there was such an irresistible preponderance of evidence on one side that conviction must have been carried into the minds of all but the obstinately perverse, it is not for us to say. But those who remember the lines of argument advanced by the opposing champions will no doubt agree with us, that if there ever was any room for doubt in the matter it arose from the difficulty—in fact, the then impossibility—of experimenting under conditions which should be precisely similar except in regard to the form of the electromotive force or current wave. It was as if we were asked to believe that blue paint was bad for a dynamo, because a dynamo of this cerulean tint happened to work exceeding ill, whereas another painted red worked exceeding well.

This essential obstacle in the path of the investigator into the influence of wave-form upon the conditions of alternate-current working has now been overcome by the ingenious and painstaking researches of Messrs. J. M. Barr, S. Beeton, and C. P. Taylor, the first portion of whose joint communication on the subject will be found in our columns this week. In the hands of these experimenters a current wave has lost its rigidity; it has become a flexible thing, which they are able to bend and mould to any pattern that they please. The sine wave, for example, may be flattened on the top, or elevated into an Alpine peak, or fashioned into other forms, without other change in the electrical arrangements than the timely "injection" into the circuit of some form of distorting influence. By regulating the epoch and the period, as well as the magnitude, of this element of distortion any desired modification of any initial wave-form can readily be effected. It will be apparent to everyone that the two most convenient means for introducing distortion are electrical resistance and electrostatic capacity, and it is these which have been employed.

Having arrived at a method of producing waves of various forms, and being able to depict graphically the shape of the waves which were being used, the next problem was to ascertain the precise influence of each wave type upon the working of alternate-current machinery, including generators, transformers, mains and electric arcs. This is, of course, the whole practical drift of the investigation; and it is interesting to learn that the influence of wave-form upon, say, transformer efficiency or arc-light efficacy is by no means the microscopic, philosophically interesting, but practically unimportant magnitude which some would have us believe. We are not yet in the position to publish the actual figures, which will, however, be given by the author later on; but we may say that the importance of wave-form in regard to transformer efficiency is high enough to command the attention of practical alternate current men; and that in the case of alternate-current arc lamps the importance is even greater than with transformers.

The theory that the temperature of the electric arc is regulated by the vapourising point of carbon, although somewhat shaken, is not likely to be wholly shattered by the tentative and unfinished experiments of Mr. W. E. Wilson, some account of which he recently gave in a Paper before the Royal Society. Mr. Wilson believes that the temperature of the arc decreases as the surrounding pressure is increased, in which case, if there is any connection between the two things, the emissivity and the vapourising temperature are an inverse function of each other. And certainly it does seem that, in an atmosphere of nitrogen, increase of pressure causes a diminution in the emissivity. But evidence is wanting as to the corresponding effect of changing the pressure with atmospheric air, or, better still, with an absolutely inert gas, which nitrogen is not. Moreover, the author does not state whether any change was made in the total number of watts supplied to the arc as the pressure was increased; his statement that "the current could be varied from 40 to 10 amperes" being very vague. Mr. Wilson, in fact, leaves us on the horns of a dilemma—namely, that if the temperature of the arc is not identical with the vapourising point of the carbon we are unable to account for the volatilisation which goes on at a constant and well-determined rate; while, if the temperature *is* identical, we are quite unable to reconcile the fall of temperature, on rise of pressure, with the well-established laws of thermo-dynamics of vapours.

At a recent meeting of the Berlin Elektrotechnischer Verein the important question of the disturbance caused by electric traction currents to physical laboratories was discussed at some length. Prof. Kohlrausch, who was in the chair, stated that experiments carried out on May 27th resulted in a considerable disturbance of the more delicate instruments belonging to the Reichsanstalt. The galvanometer deflections amounted to as much as 1·2min. of arc, the irregularities being of such a capricious nature as to exclude all possibility of precise observation. Unless these disturbances could be removed, Prof. Kohlrausch said that he would have to continue his opposition to the proposed electric equipment of the Berlin-Charlottenburg tramway, the largest deflection which could be permitted being ·1min. of arc. Herr Wilhelm von Siemens stated that he thought electrical engineers would be able to reduce these disturbances to the required figure by making use of the three-wire system of traction. Prof. Dorn, however, thought that there was no reason why we should not all revert to the double-trolley system, and argued that it was of prime importance to secure the Reichsanstalt immunity from disturbance. Only one professor was found in the ranks of the enemy, namely, Prof. Slaby, who maintained that, in view of the probable future adoption of electric traction on a large scale, it behoved those in charge of physical laboratories to accept the inevitable and make suitable arrangements for their own defence; though as to what these arrangements were to be Prof. Slaby gave no hint.

It is impossible, it seems to us, for any general rule to be laid down in regard to the relative rights of physical laboratories and electric railways. In some cases it is obvious that the immense importance of the scientific work being carried on at a given institution must outweigh the question of public convenience, although in the majority of cases it will be well for Prof. Slaby's advice to be taken to heart, and for those responsible to devise means for protecting their delicate instruments, rather than to trust to Parliament to throw out the Bill of any and every electric railway threatening to incommode those engaged in physical, educational, and research work. At any rate, so far as the Reichsanstalt is concerned, there will be a general consensus of opinion that the work it carries on is of such great international importance that an electric tramway cannot be allowed to interfere with it.

One can quite understand that in view of the recent gas explosions, the various local authorities of London would be somewhat circumspect in granting permission for the laying down of any novel, untried, or possibly dangerous type of electric main. The refusal of the Kensington Vestry to sanction the use of armoured cables in their district is, however, somewhat extraordinary. If it was the fear of gas explosions that influenced the Vestry's decision, one can only remark that it is impossible to imagine any system of mains so certain to be absolutely free from explosion troubles as a network of heavy armoured cables laid direct in the ground, and even if the armoured cables are run through iron pipes so little space is left for the accumulation of gas that they might well be reckoned as less liable to suffer from the negligence of the gas companies than many other systems of mains which could be named. Of course, the gas explosion scare may have had nothing whatever to do with the Vestry's veto on the use of armoured cables by the Notting Hill Company. If so, it would be interesting to learn exactly what it is that has brought armoured cables under the parochial displeasure. That there is death in the pot we have known on good authority for some few years; can the Kensington Vestry by any chance have unearthed a new danger to modern man in armoured cables?

The reason for the action of the Vermont Electric Company, in giving each motor a meter, even where the same customer employs several motors, is not stated in the brief description of that Company's Winooski station, which we reprint in another column; but the course thus adopted is likely to lead to, at any rate, one useful result. It may be objected that the use of several small meters is more costly than the employment of a single large one, and, with meter rents as high as they are in this country, this objection would, from the customer's point of view, certainly be valid. Meter rents may, however, be unheard of in Vermont. In any case useful information should be accumulated by the supply company which uses meters so lavishly. Motors on one class of load will differentiate themselves from motors on another class; the load factor of, say, a sausage machine will probably prove to be different from that of a dinner lift, and as a consequence, the supply company should ultimately be in a position to introduce an advantageous system of differential charges, based on the demands on the mains likely to be made by the several classes of motors.

The Presidency of the Royal Society.—It is probable that Sir Joseph Lister will be Lord Kelvin's successor in the Presidency of the Royal Society. Lord Kelvin's five years of office expire this year.

Cable Interruptions:

	Date of Interruption.	Date of Repair.
Mollendo—Arica ...	June 4th, 1895.	June 15th, 1895.
Mozambique—Laurenço Marques	June 9th, 1895.	June 17th, 1895.
Arica—Iquique ...	June 13th, 1895.	June 17th 1895.

The "Electrical Journal."—From San Francisco comes the news that yet another new American electrical periodical is about to make its appearance—the *Electrical Journal*, which is to be an illustrated monthly review of the industrial applications of electricity, gas, and power.

The State of Electrical Trade in America.—According to the latest issue of *Electricity*, of New York, which has reached us, the "condition of affairs in the electrical trade" of America "is worse than unsatisfactory." Our contemporary asserts that "not one concern in twenty is making even a moderate interest upon the capital invested."

Electric Traction for Milan.—An agreement between the Edison Company of Milan and the Corporation of the same town has just been signed, by which the former acquires the right to work the entire tram system of the town by electricity for 20 years, commencing at the expiration of the old tram company's concession in 1896.

The Theric-Oblasser Accumulator in Switzerland.—A company has just been formed in Freiburg, to be known as the Société Germano-Suisse de l'Accumulateur et des Procédés Theric-Oblasser, to acquire and work the Theric-Oblasser accumulator patents in Switzerland and Germany. The capital of the Company amounts to £30,000.

The Telegraph Service in Paris.—On the 1st prox. a new order relating to the telegraph service in Paris comes into force. At present at many telegraph offices in Paris telegrams are not accepted for delivery the same evening after 9 p.m. It has, however, been arranged that at 17 of the principal telegraph offices telegrams will, from July 1st, be accepted up to 11 p.m. for delivery the same night.

The German Electro-Chemical Society.—At the annual meeting of the German Electro-Chemical Society, held at Frankfort, a sum of 200 marks was voted to the Helmholtz Memorial Fund. It was also announced that the membership now amounted to no less than 420, as against only 65 a year ago. Prof. Arrhenius and Prof. Van't Hoff were elected honorary members of the Society.

Niagara Falls and Lewiston Electric Railway.—Work is progressing on this railway, which is to extend along the bottom of the Niagara River gorge, the road bed being about 20ft. above the level of the water. A great amount of blasting is required to cut a bench for the road bed in the steep, rocky walls of the gorge. The line will be double track, standard gauge, and will be equipped with observation cars, having all the seats facing the river.

Royal Society.—The following Papers were down for reading yesterday:—Capt. Creak, F.R.S., "On the Magnetical Result of the Voyage of H.M.S. 'Penguin,' 1890-93;" Prof. J. Larmor, F.R.S., "A Dynamical Theory of the Electric and Luminiferous Medium. Part II.—Theory of Electrons;" J. W. Rodger and W. Watson, "On the Magnetic Rotation of the Plane of Polarisation of Light in Liquids. Part I.—Carbon Bisulphide and Water."

The Laval Steam Turbine.—The Laval steam turbine is rapidly coming into favour in connection with electric lighting work in France. During the twelve months ended with February last the Company exploiting the French patent rights disposed of no less than 39 sets of combined turbines and dynamos, representing an aggregate horse-power of 1,038. The largest set was one of 300 H.P., supplied to the Société d'Eclairage et de Force par l'Electricité of Paris.

A Unit of Sound.—Mr. Hiram S. Maxim has written to *Engineering* to suggest that there ought to be a standard of sound. He advocates some form of telautographic record on smoked glass as a suitable means for embodying the standard and for comparing it with other sounds. Mr. Maxim thinks that such a standard would be useful in cases where the noise of machinery is made the ground of an action at law; as the noise of the machinery could be compared with "the noise produced by a Salvation Army band, or with other disagreeable sounds which are tolerated by law, at the same distance."

The c.-s. "Mirror."—Sir John Pender and a party of guests left Gravesend on Saturday morning in the Eastern Telegraph Company's cable-steamer "Mirror" to take part in the opening of the Baltic Canal at Kiel. The guests include Viscount Peel, Viscount Wolseley, Mr. Bayard (the United States Ambassador), Lord Charles Beresford and General Ardagh. Mr. F. E. Hesse, Secretary of the Eastern Extension Telegraph Company, accompanies the party. On Wednesday, the Hamburg Senate invited Sir John Pender and his guests to take part in the great banquet held at the New Rathhaus After the celebration the "Mirror" proceeds to Denmark and Norway, touching Scotland on her return.

Damage by Lightning.—During a severe thunderstorm at Helpringham, South Lincolnshire, last week, three agricultural labourers, who were returning home from work, were struck by lightning. One of them was killed, and the others severely injured.—During a brief but severe thunderstorm which passed over the Lochaber district last Wednesday week, a flash of lightning entered the Ben Nevis Observatory, fusing the telegraph wire and damaging an instrument at a point where the wire was exposed. The lining of the Observatory, which consists of wood and dry felt, caught fire, but, fortunately, the flames were prevented from spreading.—It may also be of some interest to learn that at Rome last week lightning struck the main circuit of the town lighting, extinguishing all the electric lights in the city. The power for the electric lighting, it will be remembered, is transmitted overhead from Tivoli.

Water Power at Minneapolis.—According to the *Electrical Engineer* of New York, the project of building a new dam across the Mississippi River at Minneapolis, which has been discussed for over a quarter of a century, is at last under way. The dam will be erected by the Pillsbury-Washburn English Syndicate. Its object is to utilise the power which has for so many years been wasted, and to increase by one-half the water power of the City of Minneapolis. The power will be used in generating electricity for general purposes. The dam will be two years in building. It and the power-house will cost about £200,000, and for the expenditure of this sum the Syndicate expects to realise about 10,000 H.P. The dam will be 900ft. long. The power-house will contain 40 turbine wheels, arranged to be used in sets of four. In times of low water the flour mills of the city are now compelled to use steam, so that the profits of milling are largely decreased. The new dam gives more than enough cheap power for all the needs of the city.

A Natural Science Studentship.—*Nature* announces that the Board of Managers of the Arnold Gerstenberg Studentship, at Cambridge University, give notice that a studentship on this Foundation will be offered for competition in 1896. The competition will be open to men and women who have obtained honours in Part I. or Part II. of the Natural Sciences Tripos, and whose first term of residence was not earlier than the Michaelmas term of 1890. The studentship will be awarded to the writer of the best essay on one of six subjects. The essays must be sent before October 1, 1896, to Dr. Sidgwick, Newnham College, Cambridge. The studentship will be of the value of nearly £90. It will be tenable for one year only, but subject to no conditions of tenure. Among the subjects proposed for treatment are: "A statement of the physicist's 'working conceptions' of Matter and Motion, together with a discussion of the philosophical questions to which they give rise," and "A criticism of the diverse views that have prevailed from the time of Newton onwards as to the conceivability or otherwise of *Actio in distans.*"

A Salomons Scholarship at Cambridge.—Sir David Salomons, who is a graduate of Gonville and Caius College, Cambridge, has founded and endowed a scholarship at that college to be called the Salomons Scholarship. The person elected to the scholarship, which is of the annual value of £40 and tenable for three years, is required to sign a declaration that it is his *bonâ-fide* intention to enter the engineering profession as a civil and electrical engineer, and, if required by the governing body of the college, to become a candidate for the Mechanical Sciences Tripos. The first examination of candidates for this scholarship, who are required to be under 19 years of age, will be held on Tuesday, October 1st. The subjects of examination will be (*a*) euclid, algebra, plane trigonometry, geometrical and analytical conic sections, elementary statics and dynamics, and differential calculus; (*b*) physics, including dynamics and hydrostatics, with practical work. Candidates must send their names, with testimonials of good conduct and certificate of birth, on or before September 29th, to the Rev. E. S. Roberts or Dr. Reid, the tutors of the College, who will supply further information if required.

Road Traction.—Mr. Shaw Lefevre has brought in a Bill to amend the law with respect to the use of locomotives on highways. The Bill only contains one clause, and its object is to exempt carriages propelled by other than horse-power from the regulations of the Locomotives Act in cases where they were not used for traction purposes. Hon. members, he said, who had recently visited Paris would have observed that there were a not inconsiderable number of carriages propelled by petroleum, gasoline, steam, and in some cases by electricity. These carriages were completely under command, and horses were not frightened by them any more than by the ordinary traffic. The use of these carriages was practically prohibited in this country by the regulations of the Locomotives Act, which was passed with the object of applying mainly to engines used for traction purposes. Under the provisions of that Act, it was necessary that every such locomotive should be in charge of

Digitized by Google

three persons at least—one walking in front, one behind, and one driving, and the engines could not proceed at a greater speed than four miles in the country and two miles in a town, and were also subject to a licence of £10 each for every county where they were used. These regulations were totally inapplicable to the light carriages such as he had described as in use in Paris. Under the circumstances, it appeared to him to be reasonable that the House should exempt carriages of that kind from the provisions of the Locomotives Act. They would be subject to the ordinary regulations of other carriages, or to any other regulations that the House might think fit to be made by the Local Government Board.

Telegraphy without Wires.—Prof. A. E. Dolbear, writing on the above in the *Electrical Engineer* of New York, of May 29th, makes the following statement :—

"The increasing interest in the attempts to telegraph without wires, both here and abroad, makes it worth while to make mention of some facts which have been forgotten or ignored, and I venture to point out that the method which has lately been employed so successfully in England for telegraphing across a sheet of water between three and four miles wide with no connecting cable was fully described by Prof. John Trowbridge, of Harvard University, in 1880. He made his original researches between the Observatory in Cambridge and the City of Boston, between which is a time-signal wire, having the circuit broken by clock once a second. He found he could hear the clock beats a mile away from the line by connecting a telephone to a wire 500ft. or 600ft. long and grounding their ends parallel with the circuit. His experiments and conclusions are detailed in a Paper given before the American Academy of Arts and Sciences and are published in their *Proceedings* for 1880. How completely he covered this ground of doing telegraphic work by means of earth conduction will be seen by the following quotations from those *Proceedings*: 'The theoretical possibility of telegraphing across large bodies of water is evident from this survey which I have undertaken. Theoretically, however, it is possible to telegraph across the Atlantic Ocean without a cable. Powerful dynamo electric machines could be placed at some point in Nova Scotia, having one end of their circuit grounded near them and the other end grounded in Florida, the conducting wire consisting of a wire of great conductivity and being carefully insulated from the earth except at the two grounds. By exploring the coast of France, two points on two surfaces not at the same potential could be found, and by means of a telephone of low resistance the Morse signals sent from Nova Scotia to Florida would be heard in France.' This is precisely what is being done in England, carrying out Trowbridge's method. In the various descriptions of methods and operations which I have seen there is no mention of the work of Trowbridge, and whatever merit and utility there may be in this method of doing telegraph work belongs to him. Shortly after the publication of the Paper from which I have quoted, Dr. Edward Everett Hale wrote a short story for the *Atlantic Monthly*, in which these earth sheet currents played an important part. Beyond that I have never seen mention of the discovery—for it was a discovery, and an important one, too—that slight currents could be detected at relatively great distances from their source by means of a telephone connected to the ground."

Polyphase and Monocyclic Systems.— M. Blondel has addressed the following letter to the *Electrical World* of New York, giving his views as to the definition of the term "polyphase" and its relation to the "monocyclic" system of Mr. Steinmetz :—

To me the definition of a polyphase system is very simple. "Poly" means several; consequently, a polyphase system is, in the words of M. Hospitalier, the creator of the term, "a system comprising the employment of several alternating currents of different phase." I do not see why, for the sole sake of pleasing Mr. Steinmetz, we should modify a definition so clear and one so universally admitted during the last four years. Mr. Steinmeitz himself—coming from whom the new definition is still more to be criticised—would doubtless never have thought of advocating the change if the accepted definition did not have for him an entirely special inconvenience—that of causing the monocyclic system to fall into a known category. The monocyclic system is, in fact, nothing else than a *polyphase system*, by means of which two phases are transformed (for what reason we do not know, unless it is to avoid the patents of another company) into three phases or into one, according to whether the motors are starting up or working under load. To wish to modify the definition of polyphase currents in order to avoid this conclusion is evidently a radical proceeding, and one which will not be countenanced by those having no ulterior interest in the matter. By applying the same method of reasoning, we can, in fact, just as well show that a dog which can momentarily support himself on his hind legs is not a quadruped. If I may be permitted to make a trivial comparison, the monocyclic system may be defined as a two-phase animal which dispenses with one of its phases when the motors are running under load. It is, without doubt, from the considerations referred to that Mr. Steinmetz rejects the word polyphase; the ordinary public, however, which calls a spade a spade, is, unfortunately not apt to lend its attention to such subtleties, and will not be pleased by having its supposed credulity thus imposed upon. As to the system which has been the subject of this curious discussion, it is certainly very ingenious, as is everything which comes from the same capable source. I confess, however, to not having been able, any more than Mr. Scott, to see its advantage over a properly-designed two-phase system, while I do see very well that it is inferior to such a system, both in the power and efficiency of its machinery. One may assign it the finest name in the world, and change all known definitions—this will avail nothing.

Science and Technology.—The difference between the scientific and the technical society is, says *Engineering*, "much smaller than that between the poet and the mechanic. The object of the one is to search out the meaning of the great universe which incloses us all, and that of the other to turn the knowledge to account to make life easier for humanity. They are but two links in the same chain. Sometimes the links are far apart, but often they are close together, and always they are of the same material. The labours of a Faraday in deducing the laws of electromagnetic induction are very similar to those of a Wheatstone, or of a Siemens, in making a practicable dynamo. Regnault's researches into the properties of steam are not more important than the experiments of the engine builder who embodies their results in a motor of surpassing economy. Lord Kelvin is not greater when he is investigating the physical constitution of the ether than when he is quadruplexing [?] an Atlantic cable. Nevertheless humanity has made up its mind that useful practical knowledge stands on a lower footing than that which is free of all taint of utility. It does not stay to examine if there be any difference in intellectual interest between the two. The moment it sees a commercial bearing in a discovery it puts it, and its author, into a secondary position. It says of him, as does the Scripture of the ostentatious giver, 'He has his reward,' and feels absolved of all necessity of affording him further recognition. His discovery may be the result of deep thought and prolonged research, but it is technical, and, therefore, it confers no claim to admiration and fame. Herein lies an error. While it is undoubtedly true that life is more than meat, yet there is not necessarily anything debasing about that which conduces to our well-being. If a subject requires the highest qualities of our minds for its due comprehension, it does not cease to be intellectual because it simplifies the struggle for daily bread."

The Electric Furnace.—In a recent number of *Nature* Prof. Roberts-Austen gives the following description of the appearance of the interior of an electric furnace projected on the screen when the furnace is arranged for the melting of metallic chromium. Directly the current is passed, the reflected picture shows the interior of the furnace like a dark crater, the dull red poles revealing the metallic lustre and grey shadows of the metal beneath them. A little later these poles become tipped with dazzling white, and, in the course of a few minutes, the temperature rises to about 2,500°C. Such a temperature will keep chromium well melted, though a thousand degrees more may readily be attained in a furnace of this kind. Each pole is soon surrounded with a lambent halo of the green-blue hue of the sunset, the central band of the arc changing rapidly from peach blossom to lavender and purple. The arc can then be lengthened, and as the poles are drawn further and further asunder, the irregular masses of chromium fuse in silver droplets, below an intense blue field of light, passing into green of lustrous emerald; then the last fragments of chromium melt into a shining lake, which reflects the glowing poles in a glory of green and gold shot with orange hues. Still a few minutes later, as the chromium burns, a shower of brilliant sparks of metal are projected from the furnace, amid the clouds of russet or brown vapours which wreathe the little crater; while if the current is broken, and the light dies out, you wish that Turner had painted the limpid tints, and that Ruskin might describe their loveliness. The effect when either tungsten or silver replaces chromium is much the same, but, in the latter case, the glowing lake is more brilliant in its turbulent boiling, and blue vapours rise to be condensed in iridescent beads of distilled silver which stud the crater wall. Such experiments will probably lend a new interest to the use of the arc in connection with astronomical metallurgy. Lockyer has shown how important it is, in relation to such storms, to be able to study the disturbances in the various strata of the stellar or solar atmosphere. Layers of metallic vapour which differ widely in temperature can be more readily obtained by the use of the electric furnace than when a fragment of metal is melted and volatilised by placing it in the arc, in a cavity of the lower carbon.

ELECTROMAGNETIC THEORY.—LXX.*

BY OLIVER HEAVISIDE.

(Continued from page 184.)

§ 272. Fourier's theorem as exhibited by equation (53) applies to the diffusion of charge in a cable in two cases only. First, let the cable be infinitely long, all in one piece, and let it be charged initially in a periodic manner, say arbitrarily between $x=0$ and $2l$, and with repetitions of the same state in all the other sections of length $2l$. Then the expansion (53) is obviously the proper one. The function $f(x)$ represents the initial state of potential. The state at any time t later is got by introducing the time factor ϵ^{pt}, as in previous cases, in the summation on the right side. This allows the harmonic terms to subside or decay, leaving only the mean value of the initial state behind finally.

But, secondly, it answers the purpose equally well to have a finite cable, of length $2l$, with the ends joined to make a closed circuit. We may take the origin ($x=0$) anywhere, and $x=2l$, $4l$, &c., mean the same as $x=0$. Equation (53) is the appropriate expansion to employ, with the time factor introduced to indicate the resulting state at any time.

The action of the time functions is always to make the later terms in the expansion insignificant compared with the earlier, so that we may generally say that the successive terms of the summation, not counting the outside constant term, are of regularly decreasing importance. And, indeed, in making practical applications, it will be found that this is usually true for the initial state itself. We usually find that the natural order of the harmonic terms in the expansion of a function is the order of their relative importance inversely. But this property is by no means a necessary one. One or any number of terms may be wholly absent, or if not absent may be very small, and followed by bigger ones. There is then an exceptional state at the first moment, and for a certain time after. But when the decadence has progressed sufficiently we must arrive at a state of things in which the order of the terms that exist at all is also the order of their magnitude.

When a cable is closed upon itself, say as described above, the real potential, whatever it may be, is necessarily a periodic function of x. Now Fourier's theorem in the form (53) is the fully periodic form. It might therefore seem that the mere fact of the periodic character of the potential in the case of a closed circuit made the periodic form of Fourier's theorem obligatory. But this is only accidentally true, as it were. The expansion (53) is only one of an infinity of expansions applicable to a closed cable, each in its proper place. For (53) to be applicable, it is not only necessary for the cable to be closed, but also for it to be self-contained—that is, there must be no external connections imposing some restraint upon the potential or the current at a particular place. The "terminal" conditions are that V at $x=0$ and V at $x=2l$ are identical, and that C is also continuous at those places, because they are united, and in such a manner as not to interfere with the continuity of V and C. We may, indeed, choose the initial state to violate these conditions. But the violation is only momentary, for continuity is instantly established by the action of the time functions.

But suppose we put a simple leak on at the place $x=0$, everything else being unchanged. The charge in the cable will redistribute itself now in an entirely different manner. For one thing, it will all leak out of the cable, instead of settling down to a state of uniform distribution. It is obvious that the periodic form of Fourier's expansion of the initial state is unsuitable, although the real potential of the line is periodic. There is no difficulty in obtaining the proper series, though it would be too great an interruption of continuity to give it just now. The peculiarity is that although V is continuous at $x=0$ and $2l$ (except, it may be, at the first moment), C is not continuous. The discontinuity in C at the joined terminals is proportional to the potential there, by Ohm's law applied to the leak. The proper Fourier series must be found to satisfy this condition as well as that of continuity of V in order that it shall, when the time factors are introduced, represent the potential at any moment. The initial state may be chosen arbitrarily and so as to violate the conditions stated, but this is of no consequence at all in the complete solution for V at any time.

The simple leak may be generalised to any combination having a definite resistance operator, by substituting the latter for the resistance of the leak. Thus we obtain any number of Fourier series for a closed circuit, which may represent one and the same arbitrary function (the initial state). All are continuous as regards V, but discontinuous at the junction $x=0$ as regards C according to the special law imposed by the nature of the leak. That is, when t is finite; for, going right back to the moment $t=0$, there may be failure then, viz., by choosing the arbitrary initial state so as to fail to comply with the conditions.

Instead of a discontinuity in the current (or in the derivative of the potential), we may make it be a discontinuity in the potential inself. Thus, we may put a coil in circuit with the cable, doing away with the leak. And, as before, this may be variously generalised. Or we may have the potential and the current both discontinuous at the junction of the beginning and end of the cable by suitable electrical devices. In every case there is one and only one appropriate Fourier series, and there is no difficulty (save complication in detail) in finding it by seeking the solution of the physical problem of decadence of an initial state subject to the imposed conditions. On the other hand, if we eliminate the physical ideas and also the time variation, and look at the matter from a purely mathematical point of view, there are serious difficulties introduced.

The initial state may be one of equilibrium, say $V=0$ everywhere. That is, we may expand zero in any number of ways in a Fourier series. To do this, we require an external source of electric or magnetic energy. We may, for example, insert a charged condenser and coil in sequence between earth and the cable at the junction of $x=0$ and $x=2l$. Let the initial state be a charge in the condenser, but none in the cable. The initial arbitrary function to be expanded in a F. series of a very special kind is zero. The time factors make the series be finite, and express the potential at time t due to the condenser's charge. Finally, if the condenser is leaky, we come to zero potential again in the cable.

We may also require to determine a Fourier series not merely so as to express $f(x)$ (including zero as a special case) between certain limits, but also so that certain functions of the Fourier series may have special values in addition. And then connected systems of Fourier series are sometimes required, as when the line is divided into connected sections, with external conditions imposed at the junctions. Or we may have a network of cables, of the same type or different, with imposed conditions, and have to find a set of Fourier series (or other kind of series if a cable varies in its resistance, &c.), to satisfy all the conditions. And so on to any extent.

There is no difficulty in obtaining the operational solutions by the method of resistance operators in a clear and definite manner, and when that is done we are virtually in possession of the real algebraical solutions in the cases of simply periodic impressed forces, and steady and impulsive forces, and arbitrary initial states, for the conversion from operational to algebraical form involves only formal transformations. But we must now return to Fourier's theorem. The above remarks originated in the departures from Fourier's theorem required even when the function under consideration is everywhere continuous and periodic. In the treatment of Fourier series to be found in certain works, the reader can hardly find a glimmer of a notion of the subject in its general and comprehensive aspect.

§ 273. There are two special forms of Fourier's theorem in the form of a double integral which should be noted. Referring to the diagram of impulses, § 271, we see that when l is ∞ the sines u, say u_2, is reduced to represent merely a positive unit impulse at y, and an equal negative one at

* This series of articles is a portion of Vol. II. of Mr. Heaviside's work on "Electromagnetic Theory." All rights of reproduction are reserved.

Digitized by Google

$-y$. The cosines u, say u_1, on the other hand, represents a positive impulse both at y and at $-y$. The formulæ are

$$u_1 = \frac{2}{\pi}\int_0^\infty \cos sy \cos sx\, ds, \tag{56}$$

$$u_2 = \frac{2}{\pi}\int_0^\infty \sin sy \sin sx\, ds. \tag{57}$$

So, if we use these in the fundamental formula (24), or

$$f(x) = \int f(y) u\, dy, \tag{58}$$

the result on the left side, which is $f(x)$ when u is a single impulse within the limits as before stated, will depend upon the limits employed. If the limits in (58) are complete, viz., $-\infty$ to ∞, and we use u_1, we shall obtain $f(x)+f(-x)$. But if we use u_2, we shall obtain $f(x)-f(-x)$. For the impulses are double, and positive or negative as described.

We may, of course, choose the limits so as to exclude both x and $-x$. Then the result is zero. Or we may include just one of them, and get either $f(x)$ or $\pm f(-x)$. The most useful way is to exclude the whole of the negative values of x. Then (58) applied to u_1 and u_2 makes

$$f(x) = \frac{2}{\pi}\int_0^\infty\int_0^\infty f(y)\cos sy \cos sx\, ds dy, \tag{59}$$

$$f(x) = \frac{2}{\pi}\int_0^\infty\int_0^\infty f(y)\sin sy \sin sx\, ds dy. \tag{60}$$

These are very useful in the mathematics of physics, perhaps more so than the complete formula (55). The following way of looking at them is interesting. Given that

$$F(x) = \left(\frac{2}{\pi}\right)^{\frac{1}{2}}\int_0^\infty f(y)\cos xy\, dy. \tag{61}$$

Then the symbols F and f are interchangeable. That is, we also have

$$f(x) = \left(\frac{2}{\pi}\right)^{\frac{1}{2}}\int_0^\infty F(y)\cos xy\, dy. \tag{62}$$

There is a corresponding interchangeability in the other case. That is, if

$$G(x) = \left(\frac{2}{\pi}\right)^{\frac{1}{2}}\int_0^\infty g(y)\sin xy\, dy, \tag{63}$$

then

$$g(x) = \left(\frac{2}{\pi}\right)^{\frac{1}{2}}\int_0^\infty G(y)\sin xy\, dy. \tag{64}$$

The corresponding property connected with the zeroth Bessel function is that if

$$F(x) = \int_0^\infty f(y) J_0(xy) y\, dy, \tag{65}$$

then the symbols F and f are interchangeable. To prove them, put say (62) in (61), and we get (59). That is, we get an equivalent, the notation being changed. We have dy both in (61) and (62), but of course in the double integral it is desirable to have them different.

The above is the way Fourier's theorem often turns up in practice. We have an integral of the form (61) say, and we can at once deduce another one. It is not necessary to go through the work of making up the double integral, and so using Fourier's theorem explicitly. But it may not be convenient to have the $(2/\pi)^{\frac{1}{2}}$ coefficient. Then, partially sacrificing the perfect interchangeability, we may put it thus. If

$$F(x) = \frac{2}{\pi}\int_0^\infty f(y)\cos xy\, dy, \tag{66}$$

then it follows that

$$f(y) = \int_0^\infty F(x)\cos xy\, dx. \tag{67}$$

Similarly when we write sin for cos in these formulæ. Examples are numberless. One or two will suffice here to illustrate. Say that we know that

$$J_0(sx) = \frac{2}{\pi}\int_s^\infty \frac{\sin xy}{(y^2-s^2)^{\frac{1}{2}}}\, dy. \tag{68}$$

It follows that

$$\frac{1}{(y^2-s^2)^{\frac{1}{2}}} = \int_0^\infty J_0(sx)\sin xy\, dx. \tag{69}$$

Observe that the limits in (68) are not complete. From $y=0$ to $y=s$, the $f(y)$ function integrated has no existence—that is, y must be greater than s. Consequently, in (69), y must be greater than s. If y is less than s in (69) the value of the integral is zero. (We have assumed that x is positive in (68). If negative, the $-$ sign must be inserted.)

If we reversed the process and passed from (69) to (68), we should require to know that the (69) integral is true as given when $y>s$, but is zero when $y<s$. This will exclude the region 0 to s from the first integral (68).

Similarly, if $G_0(sx)$ is the companion function to $J_0(sx)$, the second kind of oscillating function, and we know that

$$\frac{1}{(y^2-s^2)^{\frac{1}{2}}} = \int_0^\infty G_0(sx)\cos xy\, dx, \tag{70}$$

when y is greater than s, but that it is zero when y is less than s, then we deduce

$$G_0(sx) = \frac{2}{\pi}\int_s^\infty \frac{\cos xy}{(y^2-s^2)^{\frac{1}{2}}}dy, \tag{71}$$

the region from $y=0$ to $y=s$ being excluded. This is like going from (67) to (66). Reversing the process, we observe that the condition $y>s$ in (71) has to be preserved in (70). Else we get zero.

As an extreme case of (61), if we take $f(y)$ to be a single unit impulse at the point $y=z$, we obtain $F(x)=(2/\pi)^{\frac{1}{2}}\cos xz$. Next, using this function in (62), we come back to the impulsive function, in accordance with (56) above. There is a similar property involved in all normal functions, since they are capable of expressing arbitrary functions, and, therefore, a single impulse. Observe that the (69) integral contains two normal functions, so that we may not only deduce (68) from it, but also another integral, by employing the inter-changeable property involved in (65).

§ **274.** Now, a few words on the reversibility of the process of getting Fourier series operationally. Given a Fourier series, say $f(x)=\Sigma A \sin sx$, can we find its meaning operationally? Of course, its immediate meaning is given by the F. itself. But what the resultant meaning of the sum of the series harmonic functions may be is not evident, and it may be rather a serious matter to find it by numerical calculation, though after all the meaning may be quite simple, a straight line, for example. There is matter for regret here, for whilst the solution of problems by F. series may be easily elaborated, the ease is confined to the formulæ, not to their calculation, which gets more and more difficult.

One way of finding the meaning may be briefly mentioned here. By the introduction of a time-factor to every term of the F. series we may make it (if of a suitable kind) represent a real physical problem in diffusion. Then $f(x)$ means the initial state. Now I have already pointed out the identity of the wave solutions and F. series. It will have been observed that we can pass continuously from the waves to the F. series. For we can construct the wave solution of a diffusion problem expressing the effect due to a given source, subject to terminal reflections, by writing down the waves themselves in operational form, first the initial waves and then their consequences in order, as done in §§ 255 to 260. Adding these together, we obtain the condensed operational solution, which may be independently obtained without thinking out the waves in detail. Finally, we can convert the result to a F. series, as explained in §§ 265 to 270 in special cases, and in a general way that will come later.

Is this process reversible? It is certainly reversible on one side, for we convert the operational solution to the wave form by algebraical division. It is not only in the simple cases of terminal earth or disconnection that the meaning of the individual waves can be ascertained, though I have not given any advanced examples in detail yet. As regards the other side, we can plainly pass from the diffusion solution in a F. series to the operational solution by simply reversing all the steps. Referring to examples before given—first, the constancy of power of the time-differentiator on ϵ^{Pt} enables us to put the circular function occurring in the F. series outside the summation sign, by taking s^2 to mean $-RS(d/dt)$. Then the summation that is left, or $\Sigma\epsilon^{Pt}$, may be converted to the operational form $\Sigma(1-P/p)^{-1}$. This series of fractions may then be summed. The final result is an operational formula with unit operand.

Digitized by Google

But if the reader will apply this reversed process to the examples in detail hitherto given, he will find that he will not be able to do it safely with his eyes shut. This is because in going from the operational equation to the F. series, certain operations are nugatory, and are omitted. So in the reversed process, they should be restored. This can only be done by careful inspection of the problem, and is a question of experience and judgment. The terminal conditions satisfied by the solution in F. series should be examined. They must be satisfied all the way through, and this will enable the complete reversal to be effected. But, though there may be troubles of the above kind to be surmounted, it is not a useless way of transforming from the F. series to waves when the sources are of a simple nature. On the other hand, should the sources be not simple, as in the case of subsidence from an "arbitrary" state, the case is altered, on account of the integration which is involved in the determination of the coefficients of the F. series, which complicates the matter considerably. We may therefore leave this question on one side.

§ 275. Another way of regarding F. series operationally will be conveniently introduced by considering an elementary example. Given

$$f(x) = \frac{2}{\pi}\Sigma_1^\infty \frac{1}{n}\sin\frac{n\pi x}{l}. \qquad (72)$$

Find what $f(x)$ means, without numerical calculation, and also without introducing time functions to make a diffusion problem. We see that $f(x)$ is an odd function of x, and that it is periodic. It is therefore sufficient if we know its meaning from $x=0$ to $x=l$.

Regard the right member of (72) operationally as a function of x in the same way as our previous functions of t. Let Δ stand for d/dx. This replaces the former p, the time-differentiator. Then first we have to convert the series to operational form as a function of Δ. This is easy. For we have

$$\sin sx = sx - \frac{(sx)^3}{\lfloor 3} + \frac{(sx)^5}{\lfloor 5} - \dots$$

$$= \frac{s}{\Delta} - \left(\frac{s}{\Delta}\right)^3 + \left(\frac{s}{\Delta}\right)^5 - \dots = \frac{s/\Delta}{1+(s/\Delta)^2}. \qquad (73)$$

Similarly, in passing, we see that $\cos sx =$ same with 1 for numerator.

Next, using (73) in (72) we produce

$$f(x) = \frac{2}{\pi}\Sigma\frac{1}{n}\frac{\frac{n\pi}{l\Delta}}{1+\left(\frac{n\pi}{l\Delta}\right)^2} = \frac{1}{l\Delta}\Sigma\frac{2}{1+\left(\frac{n\pi}{l\Delta}\right)^2}. \qquad (74)$$

We have already had occasion to employ this formula, equation (13), with ql instead of $l\Delta$. So

$$f(x) = \coth l\Delta - \frac{1}{l\Delta}, \qquad (75)$$

with unit operand understood. That is, in getting (73), we imagine the operand to start at $x=0$, and be 1 afterwards.

Next, expand the coth function in (75) by division. Thus,

$$(fx) = (1-x/l) + 2\epsilon^{-2l\Delta} + 2\epsilon^{-4l\Delta} + 2\epsilon^{-6l\Delta} + \dots, \qquad (76)$$

where we have also algebrised the $(l\Delta)^{-1}1$ in (75).

Now this equation (76) expresses the full algebraical meaning of $f(x)$ on the assumption made, namely, that it begins at $x=0$. The value of $f(x)$ is explicitly represented by (76) from $x=0$ up to $x=\infty$. It is $1-x/l$ from $x=0$ to $x=2l$. All the following terms are then zero. From $x=2l$ to $x=4l$, the first auxiliary term exists. Its value is 2, and makes $f(x) = 3-x/l$. From $x=4l$ to $6l$, the second auxiliary exists as well as the first. This adds on another 2, and makes $f(x)=5-x/l$, and so on regularly. How these jumps come about through the auxiliary terms will be explained next.

(*To be continued.*)

Telephone Cable.—The municipal authorities of Königsberg have just agreed to the laying of a telephone cable across the bed of the River Pregel. This will place the Königsberg telephone exchange in connection with the Memel-Berlin trunk line.

THE ABSOLUTE MEASUREMENT OF ELECTRICAL RESISTANCE.*

BY PROF. J. V. JONES, F.R.S.

(*Concluded from page 234*).

§ 10. I trust that I have said sufficient to make clear to you the general theory of the measurement of a resistance in absolute measure by this method. It now remains to consider very briefly the practical side of the matter, the difficulties that arise, the way in which they may be met, and the accuracy attainable. The time at my disposal does not allow me to do this at all completely, and I must content myself with touching on a few points of special importance and interest.

The first great desideratum is that we should have the rate of rotation of the disc well under control, that it should run as uniformly as possible, and that its rate should be capable of sufficiently exact determination.

The disc, axle, and bearings in my apparatus at Cardiff are of phosphor bronze (Figs. 2 and 3). The disc is insulated from the axle by well-paraffined ebonite (Fig. 4), otherwise there would be short-circuiting of part of its radius through the bearings and bed.

It was at first intended to drive the disc by rope gearing from the electromotor; but in the course of preliminary experiments, though the rope was 40 yards long, and joining of the ends took place over a length of at least 6ft., there was a sudden variation in speed, producing a distinct movement of

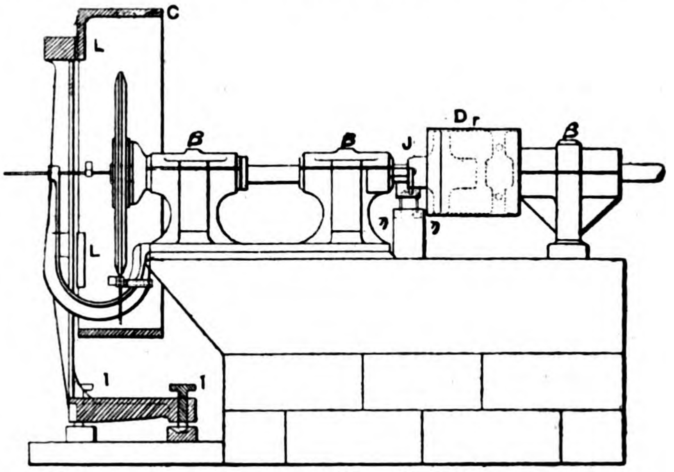

FIG. 2.—Disc and Coil. Elevation and part Section on line A B. Dr = Drum with rows of teeth on it.

my galvanometer needle, and visible at the tuning fork, of which I shall presently speak, whenever the joint passed over the pulley. The rope gearing was therefore abandoned, and the motor coupled direct. The current driving the motor is supplied from secondary cells. It passes to the motor through resistance coils, and may be increased or diminished by throwing some of these coils into or out of the circuit. It may also be varied continuously through a small range by a slide resistance of platinoid wire after the larger adjustment has been made. A shunt worked by a lever provides means of taking out or putting in a small resistance suddenly, so as to allow the observer controlling the speed while an observation is being taken to counteract small variations of speed due to alteration in the lubrications of the bearings and the friction of the brushes on the commutator of the motor. With these arrangements we can obtain any required rate of rotation from about 150 to 1,500 revolutions per minute.

It is of the greatest importance, if the observations presently to be described are to be made with ease, that the rate of rotation should remain constant for the four or five minutes required, and no effort made to compass such uniformity is thrown away. The design, workmanship, and lubrication of

* Friday Evening Discourse, delivered at the Royal Institution, May 24, 1895.

Digitized by Google

all the bearings require closest attention, and the friction between the brushes and the motor commutator should be reduced to a minimum. In my Cardiff apparatus the axle near the motor bears a heavy flywheel.

During a run the observer controlling the rate of rotation requires some test of uniformity, so that he may, if there is a quickening or slowing down, diminish or increase respectively the current through the electromotor so as to recover the initial speed.

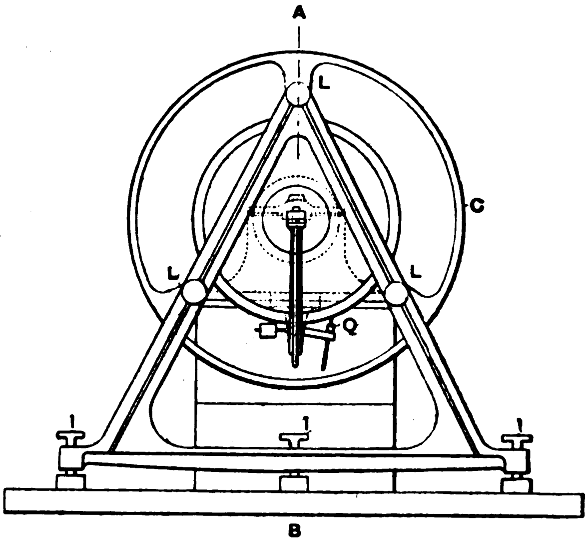

FIG. 3.—Disc and Coil. End View.

To accomplish this it is convenient to refer the rate of rotation by a stroboscopic method to a suitable tuning fork provided with riders and maintained in vibration electrically. Here is such a fork. At the end of each prong there is an aluminium plate with a slit in it parallel to the prong. When the fork is in equilibrium the slits are opposite one another, and an observer can see through both. When the fork is in vibration he can see through the slits only when they are

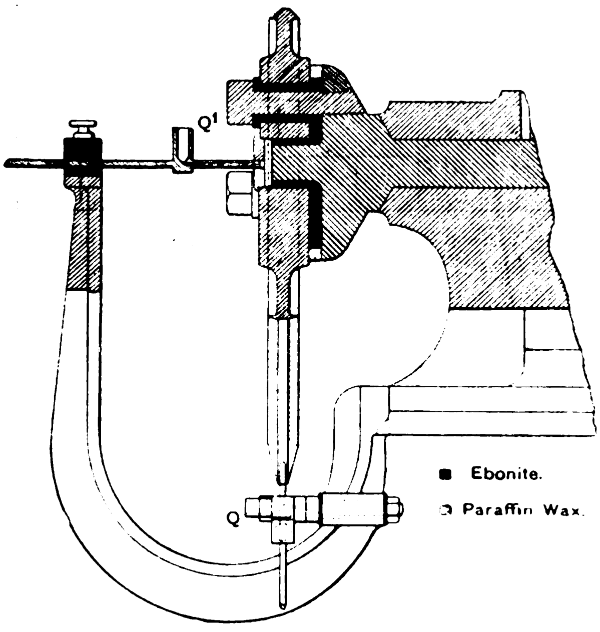

FIG. 4.—Details of Disc Insulation and Brushes. Part Elevation and part Section on lines *a b*, *b c*, Q Q^1 = brushes.

opposite one another. This position occurs twice in every complete vibration. Hence, if the number of vibrations per second is, say, 64, he obtains 128 views per second.

Now let us suppose that he looks through the vibrating slits at a drum or disc coloured black, on which a number of white spaces, which I will call teeth, are painted at equal angular intervals. Here is such a disc attached to the rotating axle; on it there are three circular rows of radial teeth.

When the disc is in rotation, if the rate of rotation is such that in the interval between two views a tooth in any row exactly takes the place of the next, that row will appear, to an observer looking through the fork slits, stationary; if it does not quite do so, the row will appear to be moving backward; if it passes beyond, the row will appear to be moving forward.

These phenomena I can show you by illuminating the rotating disc by intermittent light. The light of this alternating arc varies in intensity at each alternation, passing from maximum to maximum through a minimum that is, however, very far from darkness. Our speed is such as to make the row of 14 teeth appear almost stationary in this intermittent light. You can see the teeth, but they stand out somewhat faintly. The faintness is due to the fact that we have not complete darkness between the maxima of illumination.

We may do much better with such a tuning fork as I have described. I place its slits in front of this electric lantern, in which there is a continuous arc. The light falling on the disc has passed through the slits of the vibrating fork, and by varying the rate of revolution we obtain perfectly distinct stationary teeth. Let us suppose that the fork permits the light to pass through it 128 times per second, and that the row on the disc which looks stationary has 14 teeth on it; then one tooth takes the place of the next in $\frac{1}{128}$th of a second, but this corresponds to $\frac{1}{14}$th of a revolution, so that one revolution is performed in $\frac{14}{128}$th of a second, and the number of turns per second is $\frac{128}{14} = 9\frac{1}{7}$.

And generally

$$n = \frac{2P}{Q},$$

where P = the pitch of the fork,

n = the number of turns of the disc per second,

Q = the number of teeth in the stationary row.

We may then make the stationariness of a tooth as seen by an observer through the slits a test of the uniformity of the rate of rotation. If a tooth begins to move past a fixed reference wire placed immediately in front of the rotating disc or drum, the observer can at once bring it back by altering the current in the motor.*

If the tuning fork were itself a reliable time indicator to the degree of accuracy required, we might calculate from its pitch the speed corresponding to stationariness of a given row of teeth. But my experience is that the vibration period of a fork maintained in vibration electrically is not sufficiently constant. If stopped and set going again it may start with a period different from that of its last performance by several parts in 10,000. No previous determination of the pitch of the fork can therefore be relied on to give us the rate of rotation to a hundredth per cent., though once started the fork goes sufficiently uniformly to give us the means of control.

The period of a bowed fork does not vary in this fashion, but it is more troublesome to use for the purpose. The constant bowing required takes too much of the attention of the observer.

Accordingly, it is necessary to measure the rate of rotation during each run while the galvanometer observations are being made. This may be done telegraphically with great accuracy. The rotating disc is by means of an eccentric attached to its axle caused at each revolution to make and break an electric circuit passing through a Bain's electro-chemical telegraph instrument. The standard clock telegraphs seconds to the same instrument. The two records lie side by side on the same tape, and simple counting with careful fractional estimate gives with great precision the mean rate of rotation during the few minutes occupied in taking a set of galvanometer readings.

With this means of measuring the rate of rotation we may, establishing synchronism with a fork in the way I have indicated, find the pitch of the fork.

Table I. gives a set of measurements of the pitch of a bowed fork; I bring it before you as indicating the accuracy both of the synchronising and the time measurement.

* So far as I know this method of measuring a rate of rotation was first used by Lord Rayleigh. The method used by Macleod and Clarke for measuring the pitch of a tuning fork bears much likeness to it.

July 21	4	18·18	65·1812
July 22	4	17·96	65·1831
		Mean.	65·1820

Extreme variation from mean is about 1 in 65,000.

§ 11. When I first began working at this method I found it extremely difficult when the disc was in rotation to obtain a steady reading at the galvanometer. My galvanometer is a very sensitive Thomson reflecting galvanometer of about 1 ohm resistance, made by Elliott Bros. and fitted by my assistant, Mr. Harrison, with a long suspension for the support of the needle by a quartz fibre. When the disc was in uniform rotation the spot of light roamed continually over 50 or 100 divisions of

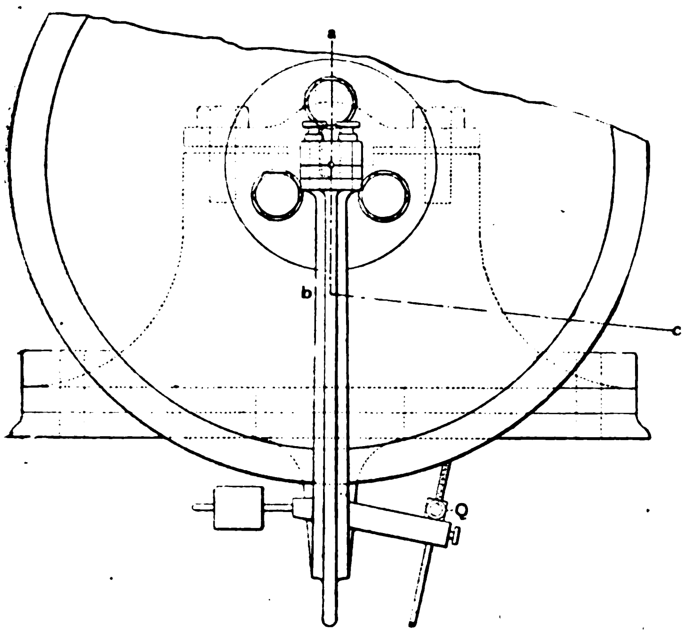

Fig. 5.—Part End View.

the scale, and frequently there were sudden jerks of a most embarrassing kind. Readings with a galvanometer so sensitive were in fact impossible. (The scale divisions are 40 to the inch, and the scale is about 40in. from the galvanometer.)

Now the electromotive force in the circuit of the galvanometer when there is no current through the standard coil is due to three causes :—

(1.) The cutting of the earth's flux of induction by the radius of the rotating disc. The electromotive force due to this cause is small in my apparatus, owing to the fact that the plane of my disc nearly coincides with the magnetic meridian. For a uniform rate of rotation it is constant.

(2.) The thermo-electric forces due to the general distribution of temperature in the galvanometer circuit. Changes in this distribution would be gradual, and would not account for the sudden irregular movements of the galvanometer needle.

(3.) The thermo-electric force at the contact of the external brush with the circumference of the disc. The sudden movements of the needle were obviously due to variations in this thermo-electric force.

I made many experiments with a view of diminishing these changes. I first tried an ordinary phosphor-bronze brush made of a number of layers of thin sheet and controlled by a spring, brush and disc circumference being well amalgamated. This was not at all successful. Trials were then made with amalgamated copper and amalgamated lead, and with the substitution of a dead-weight pressure for a spring. But no satisfactory result could be obtained.

It was noticed, however, that after amalgamation the readings were fairly steady for a short interval, and it seemed likely that if mercury could be continuously supplied to the surface of contact between the brush and disc the electromotive force at their contact would be rendered much more constant. This led on to the idea of a brush consisting of a single wire, perforated by a channel through which a constant flow of mercury might be maintained from a cistern of adjustable height, and a brush of this description was made (Fig. 5). Trial showed that our difficulty was at an end. The variations almost disappeared, the sudden jumps quite ceased to trouble us, and the motion of the needle did not extend over more than one or two divisions of the scale for many minutes. A multiplication of such brushes round the circumference would make still further improvement.

§ 12. In measuring a resistance we have to determine what I have called the equilibrium rate of rotation corresponding to that resistance—*i.e.*, the rate of rotation such that, on reversing the direction of the current through coil and resistance by the commutator, the reading of the galvanometer is unchanged.

Now, it is not very easy to hit this exactly without making a great many trials, and, fortunately, it is not necessary for us to do so. The current produced in the galvanometer circuit by the difference of the electromotive forces at the disc and at the resistance is proportional to that difference, and, if the current is small, it is proportional to the scale deflection on reversal. We shall commit no appreciable error, therefore, if we are near the equilibrium rate, in assuming that the difference between the equilibrium rate and the actual rate is proportional to the scale deflection on reversal, or, what comes to the same thing, that the difference $R - Mn$ is proportional to the scale deflection on reversal.

If we take four or five rates of rotation near the equilibrium rate, and determine the deflections on reversal corresponding to each, we can by interpolation determine the rate of rotation that would correspond to no deflection, *i.e.*, the equilibrium rate. If, say, we take five such rates, some on one side and some on the other of the equilibrium rate, we get five equations as follows :—

$$R - M n_1 = C l_1,$$
$$R - M n_2 = C l_2,$$
$$R - M n_3 = C l_3,$$
$$R - M n_4 = C l_4,$$
$$R - M n_5 = C l_5,$$

where l_1, l_2, l_3, l_4, l_5 are the deflections corresponding to rates of rotation n_1, n_2, n_3, n_4, n_5, and C is a constant.

Combining these by the method of least squares, we may readily obtain the most probable values of R and C.

If the greatest accuracy is not required, we may content ourselves with two observations, one on one side of the equilibrium rate, and the other on the other side.

The elementary observation in the determination of a resistance with any given apparatus is, then, the determination of scale deflection on current reversal corresponding to a rate of rotation simultaneously measured.

To obtain this scale deflection accurately we must obtain it as a mean of the values given for it by a number of successive reversals succeeding one another as quickly as possible, in order to eliminate slight variations in the position of the galvanometer needle due to the slight remaining variations in the thermo-electric force at the external brush contact, and the slight variations of speed that the observer at the tuning-fork has to correct. It is therefore best not to wait for the needle to come even approximately to rest after the disturbance due to the induction current on reversal; but to take the readings for the extreme positions in an oscillation, and having previously found the coefficient of damping, to calculate the position of rest from these two readings.

Here is a table of an average set of such observations taken during a three minutes' run. The readings with the commutator in one direction are denoted by E, and those with the

Digitized by Google

commutator in the other direction are denoted by W. The deflections on reversal are given in the column marked W – E.

Table II.

Coeff. of Damping $= \frac{1}{1·41}$					Mean...............	–2·57

Summing up, then, we have during an observation one observer controlling the speed by the tuning fork method I have described; another at the galvanometer continually reversing the commutator and calling out the galvanometer readings; at the same time the rate of rotation is being recorded on the tape of the Bain's telegraph instrument under the watchful care of a third; and a fourth person is required to write down the readings called out from the galvanometer. The run usually lasts one, two, or three minutes according to the degree of accuracy required.

The concordance of the results obtained from successive runs in measuring the same resistance is the best test of the success of the combination.

The following is a set of observations of a resistance of about $\frac{1}{2000}$th of an ohm made in July and August, 1893:—

Table III.

July 17th, morning.................................	0·00050016

These results show that no single observation differs from the mean of a number by more than one part in ten thousand.

§ 13. We have now to consider the other factor in the resistance—the coefficient of mutual induction of the coil and disc. This depends merely on the dimensions of the coil and disc if they are accurately centred, and as the adjustment for centre was made in between the successive sets given in the last table we may take for granted that it can be made with the requisite accuracy.

The circumference of the disc is a sufficiently true circle, the disc having being ground true in place. Disc and axle were then removed and transferred to my Whitworth measuring machine. The measurement of the disc's diameter presented no difficulty. It was easily determined to the ten-thousandth of an inch. The mean radius of my coil cannot be determined

Digitized by Google

with the same accuracy, but I believe it is known to the thousandth of an inch. The coil consists of a single layer of silk-covered wire wound in a screw thread cut in a brass frame. The silk covering of the wire introduces some uncertainty. It was measured bolted to its stand as in use. Measurements were taken along 18 diameters in the Whitworth machine with the following results :—

Diameter.	Measurement.	Diameter.	Measurement.
0°—180°	21·0898	90°—270°	21·1038
10 —190	21·0929	100 —280	21·1056
20 —200	21·0951	110 —290	21·1041
30 —210	21·0933	120 —300	21·1014

Min., 21·0898		$t=17°C.$	
	0·0158		

These measures clearly show that the coil is elliptical in section, the difference between the major and minor axes being about 0 008in., or about one part in 1,300. The way in which this fact emerges from the measurements is, however, some indication of the accuracy with which the individual measurements in the machine can be made, even in the case of a coil of insulated wire.

My coil, then, is faulty on account of this ellipticity. I have not yet calculated the possible error due to this cause; it cannot be very great. How much it is only calculation can settle; and the calculation is not without difficulty. But this, after all, is only a question of my apparatus, and does not affect the general question of the possible accuracy of the method.

A more solid metal frame might, no doubt, be turned true to the accuracy required, and if so turned might then be measured with the requisite accuracy in the Whitworth machine.

A still further improvement may be made by making the coil frame of insulating material, say paraffined marble, and winding on it naked wire instead of silk-covered wire. The radius might then be measured with certainty to something much better than 1 part in 10,000. The use of a coil with a single layer of wire instead of many layers is a great improvement for the purposes of determining the mean radius. It, of course, necessitated the finding of a new formula for the coefficient of mutual induction.

This I obtained by direct integration of the general integral for the case in point, viz., a circle and coaxial helix. The coefficient of mutual induction is given us as a sufficiently converging series involving elliptical or quasi-elliptical integrals.

We may, then, in the result conclude that, though I cannot guarantee my own coefficient of mutual induction as correct to 1 part in 10,000 till I have calculated the effect of the coil ellipticity, it lies well within the resources of our mechanical engineers to make a coil and disc free from uncertainty to this degree of accuracy. And if this be so I am warranted in stating that a resistance can be measured in absolute units to 1 part in 10,000.

Now, in the Order in Council, from which I quoted in the early part of my discourse, it is stated that in the use of the ohm standard the limit of accuracy attainable is one-hundredth part of 1 per cent.—*i.e.*, one part in 10,000. Hence the Government gains nothing in precision to compensate for the risk it has taken in adopting as unit the resistance of a standard coil, which may vary from time to time in consequence of changes in the physical condition of the coil.

There is no valid ground left for adopting as ultimate unit any other unit than the absolute unit itself. We have not in our electrical standard legislation given full credit to the mechanical engineer for what he can do for us. He can make a machine that will measure resistance in absolute units with a precision as great as—I might even say greater than—that with which the Government is prepared to guarantee its comparisons. Such a machine ought to be at work in the Board of Trade laboratory, in order that there may be opportunity from time to time, at regular intervals, to measure the Government coil or coils in absolute units. It is necessary that this should be done if we are to be guarded against the perpetual inconvenience of unknown possible changes in the coil, the resistance of which is now the legal unit.

§ 14. Such a step would have collateral advantages. It would enable the Board of Trade to certify standards of low electrical resistance. With such a machine standards of from a thousandth to a two-thousandth of an ohm may be measured to nearly the same percentage accuracy. All we have to do in dealing with the very low resistances is to pass a sufficiently large current through them, and shunt the standard coil of the machine. But to enter into details on this point would lead me too far. I must content myself with saying that I believe such a machine is much the best instrument for standardising low electrical resistances, and that accurate standards of low resistance would be of great service both in the laboratory and the workshop.

I have in conclusion only to express my obligation to my assistant, Mr. Samuel Harrison, for the great and constant help he has given me in the course of my investigations on this subject.

WAVE FORM SYNTHESIS.

BY JAMES MARK BARR, STANLEY BEETON, C. PERCY TAYLOR.

On October 5th of last year we suggested that it would be useful if a given alternate-current dynamo could be caused to produce E.M.F. waves of any desired shape for experimental purposes. It was proposed to obtain these wave forms by inserting resistance, inductance or capacity in the armature circuit at synchronously timed "epochs" and for various "intervals." We made our first trial with a small Gramme dynamo, connected up as an alternator, and we subsequently used a Ferranti machine, its frequency being more suitable for experiment.

It was found quite feasible to produce almost any wave shape at will, and we have obtained a number of interesting and important results, and we are at present finishing a series of transformer tests, which we shall supplement with some tests on the light given out by alternate-current arc lamps with widely different wave forms. Heretofore it has been necessary to employ a number of dynamos of different types in order to experiment with several wave forms, and hence the greatest advantage of the method described in this Paper is that a single alternator is made to produce the wave forms of any other types of dynamos, besides giving waves of intermediate shapes. Before describing our apparatus and dealing in detail with a number of wave forms obtained, we shall give a *résumé* of a number of the most important effects of wave forms upon the efficiency of practical apparatus. These points were brought out last summer in a dispute known as the "Sine Wave Controversy" between the American engineers and various contributors in *The Electrician*. It was this discussion which suggested the work of this article, and the arguments advanced on both sides well show the importance of the subject. It had appeared that the sine wave shape for electromotive force in alternators was regarded in America as being better than any other form for all purposes—indeed, as the *sine quâ non*. It was claimed by *The Electrician* that many practical cases existed in which other wave shapes might be better, and while that paper admitted the general lack of faults in the sinusoidal form, it objected to the belief that the latter wave possessed especial value. As in the wrangle of the two-sided shield, there was much misunderstanding in the controversy due to the fact that some controvertists spoke of electromotive force waves, some of current waves, and, judging from the points sought after by others, a number of writers dealt with curves of induction. When one said that "the apparatus was supplied with a sine wave" the whole argument depended upon whether the electromotive force wave was sinusoidal, and whether the conditions were such as to cause a distorted current wave, or whether the resultant induction waves were of the sinusoidal form. If we are to presume that all writers have referred to the same wave, we come to a perplexing instance, in the *Electrical World* of September 15, 1894, on page 264, where Prof. Fessenden entirely disagrees with *The*

Digitized by Google

Electrician, and considers the sine wave form the best—we presume that he means the potential difference wave. But he goes on to state that a "rectangular curve will give a slightly greater amount of power in a circuit for a given amount of hysteresis." If the curve referred to be the wave form of the potential difference, one experiences a difficulty in making this coincide with the statement of Mr. Steinmetz that a peaked electromotive force wave gives the smallest hysteresis loss. Again, the controversy becomes involved by assumptions with regard to the sine curve which have been based upon fallacies. We believe that Mr. Dunbar, in the *Electrical World* of August 18th, inadvertently made such assumptions. In attempting to prove that the sine wave is the best for the applied electromotive force in all cases, he first drew the strong analogy between a force, as a time function ($f(t)$), acting upon a mass, and an electromotive force sending a current through a circuit. Mr. Dunbar then says for the absolutely general dynamic case that " . . . . for maximum efficiency the ratio of the average momentum to the average force must be a maximum; that is,

$$\frac{\dfrac{\int_0^T\int f(t)\,dt.dt}{T}}{\dfrac{\int_0^T f(t)\,dt}{T}} = \frac{\int_0^T\int f(t)\,dt.dt}{\int_0^T f(t)\,dt}$$

must be a maximum. Taking the first differential coefficients and equating to zero, we have

$$\left(\int_0^T f(t)\,dt\right)^2 = \Big[f(t)\Big]_0^T \cdot \int_0^T\int f(t)\,dt.dt.$$

"Now the only function which satisfies this condition, that the square of its integral shall equal the product of the function and its double integral, is evidently that in which the integral is similar to the function (*sic*) that is the sine curve."

By the substitution of $f(t) = \sin t$ in the last expression, we get a fallacy, to wit:

$$\Big[\cos^2 t\Big]_0^T = -\Big[\sin^2 t\Big]_0^T \quad . \quad . \quad . \quad . \quad (1)$$

The limits 0 to T, if T be the period, render (1) true, inasmuch as $0 = 0$, but the members are not equal for any other limits. As a matter of fact, the general solution of the equation for efficiency does not admit of any periodic function whatever, as the value of $f(t)$, no matter what constants are inserted.

Thus, if we let

$$\iint f(t)\,dt\,.\,dt = x,$$

whence

$$\int f(t)\,dt = \frac{dx}{dt}$$

and

$$f(t) = \frac{d^2x}{dt^2},$$

we have by substitution in Mr. Dunbar's last equation

$$\left(\frac{dx}{dt}\right)^2 = x\frac{d^2x}{dt^2},$$

$$\therefore \frac{1}{x}\frac{dx}{dt} = \frac{\dfrac{d^2x}{dt^2}}{\dfrac{dx}{dt}}.$$

Integrating this we have

$$\log x = \log C_1 \frac{dx}{dt},$$

$$\therefore x = C_1 \frac{dx}{dt}.$$

Whence

$$dt = C_1 \frac{dx}{x},$$

and integrating we have

$$t = C_1 \log x + C_2,$$

whence

$$x = C_3 e^{\frac{t}{c}}, \ \&c.$$

Now this gives $f(t)$ in Mr. Dunbar's equation equal to e^t, which upon substitution satisfies equality. But this value, far from being a sine function, is *not even periodic.*

It is hardly necessary to discuss the assumptions which were made upon the fallacious solution of the above equation, and used in connection with what have been well called "ironless analogies."

The importance of the subject is shown by the fact that the discussion lasted several months, and that contributions were made by a large number of practical engineers. In such questions, we have to balance cost and design against efficiency of operation, and it would appear that there are cases where variations in wave form introduce immense differences in efficiency of apparatus in circuit. Besides this there are other considerations aside from actual efficiency. For instance, Prof. Ayrton has spoken of several specific disadvantages of peaked waves of potential difference. In these waves there is generally such a great difference between the value of the volts as read by a Cardew or an electrostatic instrument and the maximum value of the volts, that rules for insulation thickness and for spark-gap values cease to hold. This is of especial interest in the controversy, because, while a peaked wave of potential difference may in some cases be the best with regard to the efficiency of the apparatus worked, the necessarily increased cost of insulation may not justify the use of the wave.

It is really necessary to deal with the various effects of current waves and waves of induction separately, as well as the form of the electromotive force wave, and we will consider all three in this article.

Of all periodic apparatus the induction motor is perhaps the most materially affected by the form of wave of the impressed electromotive force. Broadly speaking, the general conclusion arrived at is that the sine curve is the best wave form for the motor, as will be seen by reference to the work of some eminent investigators of the subject. Mr. Kennelly, speaking with reference to power transmission in the *Electrical World* of August 18, 1894, says "deviations from the sinusoidal form of E.M.F. wave become deleterious . . . principally owing to the reactions set up in the induction motors by the virtual harmonics present in the sinusoidal form of E.M.F. whenever rotary field motors are employed." No direct experimental evidence is cited in this letter to vindicate the above statement.

Mr. Scott, however, has instanced the case of a two-phase motor, which when driven from a certain dynamo heated badly and had more "armature slip" than was expected. It was found that the curve of this dynamo was irregular and that the third harmonic was prominent. Being supplied with a sine electromotive force the same motor ran efficiently and well. Mr. Scott remarked that in a motor of this sort the third harmonic tended to turn the armature in a direction opposite to the "primary wave." It would be interesting to know the exact shape of this wave referred to as of "irregular form," for it might then be possible to suggest another wave shape before deciding that the sine wave is the best. Prof. Ryan, in a letter to the *Electrical World* of August 25, 1894, says that "it has been found that the synchronous motor works best when it produces a motor E.M.F. that has the same wave form as the generator that supplies it with power." The same applies, he says, to rotary transformers. Another point is then here brought out, but it still remains to decide which is the best wave form for the motor and generator to possess. Dr. Louis Bell, in the *Electrical World* of September 1, 1894, has also come to the conclusion that the sine wave is the best for induction motors. Dr. Bell tested a three-phase induction motor with two independent sources of power, to see which gave the best results when applied to the motor. One source gave a "very close approximation to a sine wave," and the other was an ironclad alternator, the curve of which "was never exactly a sine wave, and which was deliberately distorted by weakening the field." Mr. Kelly, in the *Electrical World* of August 11, 1894, has made a very similar test on a motor which, when driven by a "generator giving approximately a sine wave," developed 40 H.P., but was "practically inoperative . . . when working with an alternator of the same normal frequency, but with very irregular waves."

Digitized by Google

Prof. Ryan's point, that the motor and generator should give the same potential difference wave form, seems to have been overlooked in both these last two experiments. For one could hardly expect the same motor to work equally well on waves differing widely in shape. The motor, no doubt, works best when supplied with power from the generator giving the potential difference wave that most nearly approaches its own, and it is, therefore, very important to know exactly the wave form of the motor, for then we would know the best shape to give to the impressed potential difference. In both the experiments of Dr. Bell and Mr. Kelly one is again left to surmise the actual form of the wave referred to as "very irregular." It is hard to accept the verdict for the sine wave before a few other wave forms of perfectly definite shape have been tried. It seems also probable, when experimenting in this manner with two generators, that defects inherent in one or the other might seriously affect the value of the results.

Wave form is also of importance in the working of transformers. The efficiency at full load has by this time been raised to such a high value that it is not to be supposed that variations in the shape of the applied electromotive force wave can improve it much—probably not ½ per cent. at the outside. But with regard to open-circuit losses the variation with wave form becomes more important. Mr. Steinmetz has observed variations up to 13 per cent. in the iron losses of a transformer when tested with different shapes of applied electromotive force waves, and Mr. Kelly also has noted variations of 10 per cent. In the case of electrical distribution for lighting purposes in which a transformer is placed in each house it is very important to balance between the losses in the transformers and the mains. In such cases the transformers are seldom worked with a higher load factor than 10 per cent., and low-load working is by far the most important consideration. Now the mains loss depends only on the current, whereas the transformer loss depends also on the power factor, and it is evident that if the factor is increased while the transformer loss remains constant there will be a gain in the efficiency of the mains. Thus, in the question of the best electromotive force wave form for use with transformers, the power factor is quite as important as the consideration of the true watts lost. Thus, in the case of a long-distance transmission it might be better to use a wave form giving greater iron loss in the transformer than others, if the *apparent watts* were less, not only because of the loss in the mains, but because, if the power factor is low, more machines may have to be run than would be necessary for the actual true output required to avoid heating in the armatures. In the study of transformer losses with different applied electromotive force wave forms, what we really require to know is, therefore, the shape and phase of the primary current wave produced by each. A very good idea of these different current waves produced in a given transformer can be got by Dr. Sumpner's method, given in the *Phil. Mag.* in 1887. But, to quote Dr. Fleming, "this is a question which can only be settled by an experimental comparison of the no-load losses of transformers tested off alternators of which the electromotive force curve is at the same time ascertained." In order to come to any definite conclusion on the point at issue it would, therefore, be necessary to have access to a number of alternators giving a great variety of electromotive force wave forms. In this Paper we show a method by which it is possible to produce any wave form at will from one alternator, and in this way we can make a very complete set of experiments with even a greater variety of wave forms than are at present in use for alternating-current work.

It is general to speak of the total hysteresis loss as being dependent upon the highest value attained in the current wave. This is not true for wave forms having several maxima. It has been shown by Dr. Sumpner (in the *Phil. Mag.*, Vol. XXV., p. 466, 1885) and others that if, during the Ewing cycle, the current suddenly goes back to a value previously passed, and then resumes its former rate of sinking or rising, we get a loop in the hysteretic curve. Hence it follows that the waste work done in hysteresis will be greater per period the more points of inflection we have in the current wave for a given highest maximum. Thus we see that the magnetising current wave should be *smooth*. But as there is an indefinite number of "smooth" wave shapes this is not sufficient to indicate which particular form will give the least hysteresis loss for a given number of lines developed per cycle in a given magnetic circuit.

Considering the case of alternate-current arc lighting, the most interesting effects yet published are contained in the Paper read before the Verband der Electrotechniker Deutchlands last year by Herrn Rössler and Wedding. In this case the current wave is the important point, and the questions to be considered are the efficiency of the arc itself and the working of the regulating device. The experiments were carried out with only three wave forms, and although these were typical shapes, it is difficult to draw any definite conclusions from so few. If a series of waves could be taken with some intermediate and some even more marked forms, there is no doubt that some very valuable information could be obtained on this subject, which, though very important, has probably, through want of facilities, received very little attention. The importance of the subject is well shown by the results of the above Paper, namely, that the lamp tested gave 44 per cent. more light per watt with the Wechsler machine (approximately a sine wave) than with the Ganz (peaked wave). With the Siemens machine (flat-topped wave) the results are ever better, and the authors suggest that the rectangular shape is the best. It would be extremely interesting to make some experiments with forms approaching this shape as nearly as possible. Herrn Rössler and Wedding note that the *noise* is also bad with a peaked wave, but what seems really necessary is to find the best form of current wave to use for the arc itself, and to suit the mechanism to this form and not the form to the mechanism.

Drs. Crehore and Bedell, in their recent treatise on alternate currents, point out that a difference in shape between the upper and lower half waves in a period, although the areas of the two may be equal, can cause a great difference in the root-mean-square values of the positive and negative impulses. And they go on to say that such a current wave would account for unequal consumption of the carbons of an alternate-current arc lamp. This case of waves of dissimilar contour above and below the zero line, though quite outside the "sine controversy," gives us another practical instance of wave form effect which adds something to the general importance of the subject. These waves are included in the work of this article. In most cases, as in the above, the important point to be considered is the value

$$\frac{1}{T}\int_0^T i^2\,dt,$$

so that equality of current wave area with regard to the zero line tells us nothing. However, there is one case with alternate currents in which the value

$$\frac{1}{T}\int_0^T i\,dt$$

is the important point, viz., alternate-current electrolysis. This has little practical importance, as there is no application of the principle. However, a number of compounds are changed by alternate electrolysis, and if a change of current wave shape is made without alteration of areas, there would be no change of effect as in the case of operating instruments and other apparatus by unbalanced root-mean-square values.

Another instance of wave form effect has recently been brought out in the working of the Phonophore system, in which a rapidly changing intermittent current is generally employed. The wave now used may in some cases cause a disturbance in telephone lines, but by the use of an equally strong alternate current having a wave of smooth contour, noise due to inductive disturbance is rendered *nil*.

We have thus far shown the more practical aspect of the study of wave forms, and now come to the general methods of attacking the problems involved. The idea of regarding irregular wave forms in electrical work as "fundamental sine shapes possessing superimposed harmonics" (that is sine curves of intermediate period) "with lag and lead," is of recent development. It is the application of Fourier's theorem. This proposition shows that any periodic curve whatever, which represents a function of time, may be built up by adding

Digitized by Google

together a number of simple sine curves. Thus we start with a true sine curve and have, say, for the electromotive force of an alternator,

$$E = E_1 \sin p\,t.$$

And if the wave is a deviation from this fundamental shape we have

$$E = E_1 \sin p\,t + E_2 \sin 2\,p\,t + E_3 \sin 3\,p\,t + E_4 \sin 4\,p\,t + \ldots$$
$$\ldots + E_1^1 \sin\left(\frac{\pi}{2} - p t\right) + E_2^1 \sin 2\left(\frac{\pi}{2} - p t\right) + E_3^1 \sin 3\left(\frac{\pi}{2} - p t\right) + \ldots$$

&c., the number and order of the terms remaining in the expression depending upon the shape and dimensions of the wave represented. The signs and magnitudes of the coefficients $E_1, E_2, E_3, E_4, \ldots\ldots E_1^1, E_2^1, E_3^1, E_4^1, \ldots\ldots$ determine the lag or lead and amplitude values of the several harmonies with regard to the zero of the irregular wave. *Each harmonic sine curve is the resultant of each corresponding pair of terms* in the above expression, such as $E_1 \sin p t$ together with $E_1^1 \sin \left(\frac{\pi}{2} - p\,t\right)$ or $E_n \sin n\,(p\,t)$ together with $E^1_n \sin n \left(\frac{\pi}{2} - p\,t\right)$.

It is possible to construct an instrument which, when its stylus is traced over any periodic curve, will give the values of the amplitudes of the pairs of component sines which make up the "harmonics" present in that curve. Lord Kelvin, in 1876, was the first to suggest such an instrument, and two of his proposed form have been made.

These instruments were very cumbersome and complicated, and no practical improvements were made until last year, when Prof. Henrici brought out a simple and most accurate harmonic analyser. This instrument was designed by Mr. Archibald Sharp, of the engineering department of the Central Technical College, and made by Coradi, of Zurich. It is fully described in the *Phil. Mag.* for July, 1894. The harmonics present in the curves given below were obtained by the use of the latter instrument through the courtesy of Prof. Henrici. The instrument gives the first five consecutive pairs of terms for the harmonics by one tracing around curve. Another instrument having relation to a wave form work is the Harmonic Synthesyser, recently invented by Mr. Sharp. When rolled vertically across a flat sheet of paper, this instrument automatically draws in lead pencil or ink the wave form which is made up by any harmonics for which the elements are set.

Harmonic analysis being of such importance in the general study of alternate-current wave form, practical development has led to several purely electrical methods for resolving the wave shapes into their components. Profs. Ayrton and Perry, some years ago, used a Siemens dynamometer, through the movable coil of which was passed the current to be analysed. A current of constant value having a pure sine form and a frequency which could be varied at will, without altering this constant value, was passed through the fixed coil. The latter alternating current was obtained by the use of a revolving liquid commutator which has since been used by Prof. Ewing and Mr. Lamb, and used also in America by Dr. Louis Duncan. The frequency of the known sine wave, beginning at a low value, was gradually increased until the first critically-marked deflection was observed. This gave the fundamental sine wave, and the magnitude of the attraction gave the amplitude of the component. The frequency was then gradually increased until an attraction was again observed between the dynamometer coils from which the frequency and amplitude of the first higher harmonic was determined, and so on for all other components.

Dr. Pupin, of Columbia College, New York, has recently brought out an analogous method of analysis involving the use of an electrometer. The components are in this method separated by successive resonant effects. Other physical methods of harmonic analysis have been used with success.

(To be continued.)

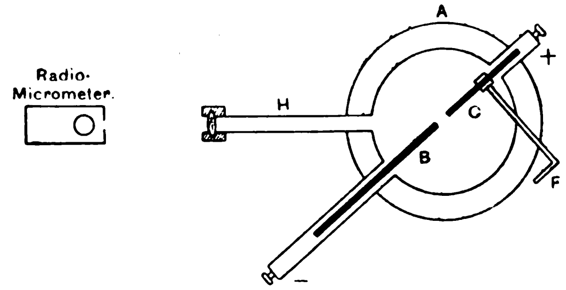
Electric Lighting by Wind Power.—The electric light plant at Sunnyside Asylum, Dundee, derives its motive power from a Blyth windmill of about 10 H.P. The mill is said to be giving very satisfactory results. The Blyth windmill is constructed to move in a horizontal plane about a vertical axis.

ON THE EFFECT OF PRESSURE OF THE SURROUNDING GAS ON THE TEMPERATURE OF THE CRATER OF AN ELECTRIC ARC LIGHT.*

BY W. E. WILSON.

Of late years it has often been assumed that the temperature of the crater forming the positive pole of the electric arc is that of the boiling of carbon. The most modern determinations give this point as about 3,300°C. to 3,500°C. Solar physicists have thought that the photosphere of the sun consists of a layer of clouds formed of particles of solid carbon. As the temperature of these clouds is certainly not below 8,000°C., it seems very difficult to explain how carbon can be boiling in the arc at 3,500deg., and yet remain in the solid form in the sun at 8,000deg. Pressure in the solar atmosphere seemed to be the most likely cause of this, and yet, from other physical reasons, this seemed not probable.

In order to investigate whether increased pressure in the gas surrounding an electric arc would raise the temperature of the crater, I had an apparatus made by the Cambridge Instrument Company. It consists of a strong cast-iron box, which was tested by hydraulic pressure to 2,000lb. per square inch. In the following plan, A is the box, B and C are the two carbon poles enclosed in steel tubes. The negative carbon was kept in position against a copper ring by a spiral spring behind it. The positive carbon was hand fed by a friction roller, which was moved by a handle F outside the box. A steel tube H was screwed into the box at such an angle that, by looking down it, we could see well into the crater of the positive pole. The end of this tube is closed by a glass lens, which formed an image of the crater at a distance of 80cm. A Boys' radio-micrometer, with its aperture reduced to about 2mm. diameter, was so placed on the pier in the laboratory that the image of the crater fell on its small aperture. The instrument thus gave deflections proportional to the radiation coming from the crater. The



current was supplied from a battery of accumulators, giving an E.M.F. of 110 volts. Suitable resistances of platinoid wire were put in the circuit, so that the current could be varied from 40 to 10 amperes. An ammeter was also in circuit, and the poles of the arc were connected to a voltmeter.

The gas used was nitrogen, and the pressure was got by connecting the box by a copper pipe with the valve of a 20ft. steel cylinder filled with the gas at a pressure of 120 atmospheres. A T-joint on the copper pipe was connected with a Bourdon pressure gauge, which showed the pressure in the box at any moment.

The method of experimenting was first to start the arc with the pressure in the box at that of the atmosphere. The image of the brightest part of the crater was thrown on the aperture of the radio-micrometer, and a series of observations taken of the deflections of the instrument. The pressure was then gradually increased, and the maximum deflections observed. As the pressure rises the resistance of the arc increases, and, in order to keep the same current flowing, the resistance in the circuit was reduced. It soon became evident that, even with moderate pressures of about five atmospheres, the temperature of the crater had fallen. This was not only shown by the reduction in the deflections of the radio-micrometer, but also by the fall in brilliancy of the image of the crater to the eye. The pressure was then increased to about 20 atmospheres, and the brilliancy of the crater fell to a dull red colour. These experiments were repeated several times, and always with the same results.

I then tried the effect of reducing the pressure in the box by means of an air pump, but as some of the glands in the box were only intended for an internal pressure, I found it impossible to get a good vacuum; yet by keeping the pump at work, and thus getting a moderate vacuum, I found the radiation of the crater to be much greater than at the atmospheric pressure.

The temperature of the crater seemed very sensitive to any sudden diminution of pressure in the gas. If the blow-off valve was suddenly opened, the brilliancy of the crater fell so much

* Paper read before the Royal Society. Preliminary notes of observations made at Daramona, Streete, co. Westmeath.

Digitized by Google

that it became nearly invisible. When the box was being exhausted by the air pump, although the temperature of the crater was rising as the vacuum improved, yet at each stroke of the pump the eye could see a distinct falling off of brilliancy in the image. It was thought that the diminution of brilliancy might be due to smoke inside the box, but on looking through the window everything was seen sharply defined, also the gas as it issued from the blow-off was perfectly clear. The arc was also kept burning for some time in the box at the atmospheric pressure, but the image remained quite clear, and the inside of the box seemed quite free of smoke.

From these experiments it would seem as if the temperature of the crater, like that of a filament in an incandescent lamp, depends on how much it is cooled by the surrounding atmosphere, and not on its being the temperature at which the vapour of carbon has the same pressure as the surrounding atmosphere. That carbon volatilises in some form at comparatively low temperatures seems likely, from the way in which the carbon of incandescent lamp filaments is transferred to the glass. The pressure of the vapour of carbon in the arc may consequently be very small, and further it would seem that the supposition of high pressures in the solar photosphere, which has been referred to in the beginning of this Paper, is not borne out by these experiments, and that carbon may exist there in the solid form at very high temperatures, although the pressures are comparatively low.

The experiments on high pressures were conducted on several occasions. On the last occasion, in addition to repeated former experiments, the experiments on reduced pressures were performed, and I then had the great advantage of the presence, advice, and assistance of my friends Prof. Minchin and Prof. G. F. Fitzgerald. The later series of experiments entirely confirmed my former ones.

PHYSICAL SOCIETY.

At the ordinary meeting of this Society, held on June 14, 1895, Captain W. de W. Abney, President, in the chair,

Mr. Burstall continued the reading of his Paper on

"The Measurement of a Cyclically Varying Temperature."

Three sizes of platinum wire have been employed for the thermometers in order that some idea might be formed as to the magnitude of the error caused by the lag of the temperature of the wire behind that of the gases. The constants of the platinum thermometers were determined either by comparison with a standard Callender platinum thermometer or by means of ice, boiling water, and boiling sulphur. In most cases the thermometer constants were determined after the wire had been exposed to the action of the hot gases for about half an hour. One wire, however, was calibrated before being used, and an unusually high value was obtained for the coefficient δ. After this wire had been exposed to the hot gases the value of δ fell, however, to the normal. The author thinks the abnormal value may have been due to the formation of a gold platinum alloy during the process of attaching the wire to the leads, and that this alloy was subsequently swept off by the hot gases. The Paper includes a number of tables and curves which embody the numerical results, and show that concordant results can be obtained on different days and with different thermometers.

Prof. PERRY said that an instrument for quickly recording varying temperatures was greatly required by engineers. The temperature just inside the cylinder walls was, however, the most important to determine, and a knowledge of how the temperature from one to two millimetres inside the walls varied would be of the greatest importance. He would like to ask the author if the observed temperatures agreed with the values calculated on the assumption that the gases in the cylinder behaved as a perfect gas, and that $\frac{PV}{T}$ was constant during the whole stroke. Differences between the observed and calculated values might be due to dissociation, and not entirely to lag in the thermometers. It was astonishing that even the fine wires employed were able to follow the rapidly varying temperature, and he would like to see some special experiments made to test this point.

Prof. CAPPER showed a diagram giving the values calculated on the assumption that $\frac{PV}{T}$ = constant. In such a calculation it was necessary to assume some temperature as a starting point, and in general this temperature was obtained from an analysis of the exhaust gases, so that the calculated curve is most likely to depart from the truth at the commencement of the stroke. He (Prof. Capper) hoped that the author would be able to accurately determine the temperature of some one point of the stroke, and he suggested that the point where the observed curve crossed the theoretical curve would be the most suitable one for this purpose. Such a point must exist, since at the commencement of the stroke the lag causes the observed temperature to be too low, while at the end of the stroke the observed temperatures are too high. Mr. Burstall finds a curious bump in his curves, and it is curious that a similar bump exists in the calculated curves. From the constancy with which this bump appears it would seem that it must have some physical meaning. It was important to remember that the expansion in the gas engine cylinder is not adiabatic, for heat is both abstracted and generated during the stroke.

Mr. BLAKESLEY suggested that, since the temperatures dealt with were sufficient to make the wire red hot, the question of lag might be investigated by the wire being examined by means of Becquerel's phosphoroscope at a known interval after the removal of the source of heat.

Mr. GRIFFITHS said he considered an important source of error was the large thermal capacity of the leads when the working wire was so very short. He thought it would be possible to standardise the thermometers under conditions somewhat similar to those which occur in the engine cylinder. Thus, perhaps, alternate gushes of air at 0°C. and 100°C. might be used. The use of gold to attach the fine wire to the leads was objectionable, since the gold must permeate the platinum for quite an appreciable fraction of the whole length of the wire. He would like to know whether the change in δ alluded to by the author occurred with the first explosion, or whether it was a gradual one.

Mr. ENRIGHT pointed out that the nature of the working substance in a gas engine varied during the stroke.

Prof. PERRY said that the change in the specific volume of the gases before and after combustion did not amount to more than 1·25 per cent.

Mr. E. WILSON said he thought it was most important to shorten the time of contact, since at present the galvanometer readings corresponded to the mean temperature over a range of about 5 per cent. of the whole stroke. It might be possible to make use of a condenser to get over this difficulty.

Prof. RUCKER said that the Kew Observatory were making arrangements to undertake the testing of platinum thermometers.

Mr. ENRIGHT suggested that with a very short contact induced currents might cause errors.

The author, in his reply, said the only chemical action on the wires he thought probable was the formation of a carbide. After several hours' use, however, the wires appear quite bright and clean.

A Paper on "An Electromagnetic Effect," by Mr. F. W. Bowden, was postponed till the next meeting.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

WEDNESDAY, June 26th.

Society of Arts.

4 p.m. Annual General Meeting.

THURSDAY, June 27th.

University College, London.

8.30 p.m. Annual conversazione.

FRIDAY, June 28th.

Physical Society.

5 p.m. Meeting at Burlington House. Papers to be read: (1) "An Electromagnetic Effect," by F. W. Bowden; (2) "On Synchronous Motors," by W. G. Rhodes; (3) "The Electrical Properties of Selenium," by Shelford Bidwell, F.R.S.

The Electrical Equipment of the "Terrible."—The electric machinery for generating the current for internal lighting, search-lights, motors, &c., on board the new cruiser "Terrible" consists of three large sets of condensing engines and dynamos. The engines, says *Engineering*, are of the open-fronted compound type, mounted on the same bedplate, and coupled direct to direct-current dynamos, each capable of generating 600 amperes at an electromotive force of 80 volts, at 300 revolutions per minute. Two of these sets are placed in a compartment adjacent to the main engine-room and under the protective deck, the third set being placed on the main deck amidships. The electric light installation consists of about 800 50-c.p. and 16-c.p. lamps, laid out on the double-wire, water-tight distributing system. In addition to the lighting up of the interior spaces, including coal bunkers and magazines, the decks will be illuminated by powerful lights suspended from the rigging. The compasses, telegraphs, mast-head, side lamps, signal lanterns, semaphores, and military tops are all separately lighted and under the immediate control of the officer on deck. Six search lights are fitted up—two on the forward bridge, two on the after bridge, and one on the top of each mast. Electric motors are to be used throughout in lieu of the usual hydraulic appliances—and this applies not only to the training and elevating of the large guns, but also for the ammunition hoists, &c.

The Electrician.

(The Oldest Electrical Journal, 1861—1878.)

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny
Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

'THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN' are as follows:—

	YEAR.	HALF-YEAR.	QUARTER.
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to* 4 *p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is in preparation.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. 93 original illustrations, handsomely bound, price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

THE WORK OF HERTZ. By Dr. O. J. LODGE. Price 2s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c. By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. *[In preparation.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. *[In preparation.*

SPECIAL NOTICE.

Owing to the growth of the electrical and allied industries the demands for space in "THE ELECTRICIAN" are, for the greater part of the year, so pressing that a permanent increase in the size of the journal has become necessary. To meet the increased cost involved by this step, and by other improvements, such as heavier paper and more numerous illustrations, the price of "THE ELECTRICIAN" has from May 3rd been advanced to 6d.

The Subscription to "THE ELECTRICIAN," commencing with Vol. XXXV. (May 3, 1895), is as follows:—

	YEAR.	HALF-YEAR.	QUARTER.
United Kingdom......	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

NOW READY.—Vol. XXXIV. of "THE ELECTRICIAN," bound in strong cloth. Price 12s. 6d., post free 13s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

POLYPHASE PATENT LITIGATION.

It has often been asked, Why has the transmission of power by polyphase currents made so little progress in this country, in comparison with its use on the Continent and in America? This difference cannot be wholly attributed to ignorance on the part of British manufacturing firms, nor even to a natural conservatism tinged with the feeling that the advantages of polyphase motors have been somewhat overstated. The cause of the delay in this country has, we think, to a large extent been due to the uncertainty that exists as to what claims would be made by the owners of certain patents, and as to the ground that they considered covered by those patents. British firms have hardly yet sufficiently recovered from the costs and expenses incurred in litigation over compound winding, over incandescent lamps, and over telephones, to wish again to embark without due consideration on the troubled waters of the law. Nor is that feeling unjustified in view of the position which affairs have now assumed in America. The Westinghouse Electric Company, which controls the patents and inventions of NIKOLA TESLA, have instituted suits against the General Electric Company of America, and against the Stanley Manufacturing Company, for alleged infringements of TESLA's patents, claiming, as their advertisements state, that these patents cover broadly any system of polyphase alternate current distribution of power. It is interesting to note, as showing how broad is the ground

Digitized by Google

claimed, that neither in the "monocyclic" system of the General Electric Company, nor in the two-phase system of the Stanley Manufacturing Company, are the motors simple rotary field motors, but modifications which have the appearance of being expressly designed to avoid any claim on behalf of the owners of TESLA's patents. The results of these actions will be regarded with interest in Europe, as it is only to be supposed that if successful in America a similar line is likely to be taken in this country and elsewhere where TESLA's patents are in force. That this question is not lightly regarded by the owners of the TESLA patents is evident from the fact, that the valuation of the TESLA patents is said to have been the point at which the recently negotiated "combine," as to patents, between the General Electric Company and the Westinghouse Company, came to a deadlock.

The ground on which the priority of TESLA's patents is likely to be contested, is probably the, till recently, forgotten rotary field motor of BAILY (1879), and the motors of FERRARIS; but these do not appear to entirely touch the issue. In the first of these the rotary field was produced by commutating a continuous current; in the second, by splitting a single-phase alternating current into two phases by proper arrangements of self-induction or condensers. This is a different thing from the reproduction in a motor of a rotating magnetic field, the image or reflection if the term may be used, of an existing rotating magnetic field, produced in a dynamo with multiple coils, connected to similar coils in the motor. This is the kernel of TESLA's inventions, and it remains to be seen whether his patents of 1888 will withstand the fire to which they will now be exposed. The Westinghouse Company, in any case, can claim little credit for the practical introduction of polyphase motors, for whilst the patents date back to 1888, for some years after this no definite information as to the results that had been obtained by their use was forthcoming, whilst even as late as 1894, the current lists of the Westinghouse Company, only described and showed their use, like FERRARIS' motors, on single phase transmission plants for starting up synchronous motors. The credit of showing what it is possible to effect with polyphase transmission will always be connected with the names of C. E. L. BROWN and DOLIVO-DOBROWOLSKI. It is to be hoped, in the interests of all parties, that this question will be settled shortly and decisively, as until its conclusion a cloud will necessarily hang over a system which, in many cases, may prove of considerable value.

Meanwhile it is interesting to note what is the real position now to be assigned to polyphase power transmission and distribution, in what respects it is superior to continuous current systems, in what respects it is inferior. The answer in general terms is this, where the transmission or distribution is satisfied by motors running at a constant speed, and not requiring a turning moment greater than, say, 50 per cent. above the full load running moment, no system can beat the polyphase, either in economy in first outlay, simplicity of working or efficiency. But where variations of speed are required, or a largely increased turning moment is necessary, either at starting or when running, polyphase plant is not applicable. Great loss of efficiency always occurs when a polyphase motor revolves at a speed differing considerably from the speed of the revolving field, and the turning moment appears at any speed to have a maximum beyond which a reduction of speed decreases instead of increasing it, thus producing instability. These generalisations omit the consideration of the possibility of using higher pressures owing to the power of transforming alternating currents with simple apparatus. It may, therefore, be taken that with polyphase motors as at present made, they will be used for transmission of power in manufacturing, but for mining, for traction, for lifts, and analogous purposes, continuous current machinery may be expected to hold its own.

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(Continued from page 231.)

44. **Loop Tests.**—Where duplicate cables exist, a fault in either one of them can be localised with considerable accuracy by one of the loop tests. The faulty cable is joined or looped to the good cable at one end, thus forming one continuous circuit. There are, therefore, two cable ends at the testing station to put on to the bridge.

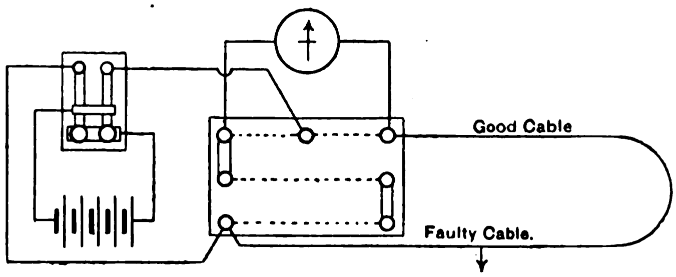

FIG. 124.—Metallic Circuit.

In Varley's loop test the end of the faulty cable is joined to the earth terminal of the bridge, and the end of the good cable to the line side. The metallic circuit is first measured—that is, the copper resistance of the looped cables, irrespective of the presence of a fault. For this test the earth side of the key is connected to the bridge (as in Fig. 124), instead of to earth, so that the fault does not form part of the circuit tested. The earth side of the key is then disconnected from bridge and put to earth (Fig. 125), and a set of readings taken with zinc and copper. The fault being in the battery circuit, no change in its resistance affects the result. The resistance unplugged, added to that of the short length of cable up to fault, is equal

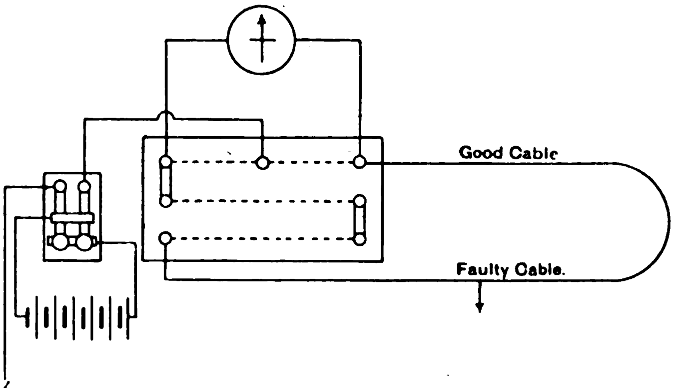

FIG. 125.—Varley Loop.

(when balance is obtained with an even ratio in the bridge) to the resistance of the rest of the cable. That is, the resistance is equal on each side of the fault, and the distance of the fault in ohms is, therefore, half the difference between the resistance of the looped cables (or metallic circuit) and the unplugged resistance.

In Murray's method the cable ends are connected direct to the bridge ratios without an added resistance. One of the bridge ratio coils is usually fixed and the other adjusted to balance. The only changes from the Varley connections are to reverse the cable ends, and shift one connection of the galvanometer and one of the keys. We then have the connections shown in Fig. 126, the fixed arm *a* being a low resistance (usually the 10-ohm coil), on account of being next the shorter length of

* Copyright. All rights reserved.

Digitized by Google

cable to the fault. If μa is the resistance unplugged in the box to balance, we have the distance of fault in ohms equal to—

$$\frac{\text{Metallic circuit resistance}}{\mu + 1}.$$

Thus, with a metallic circuit of say 6,250 ohms (measured as in Fig. 124), the arm a 10 ohms, and the unplugged resistance say 1,240 ohms, we have $\mu = 124$, and distance to fault—

$$\frac{6{,}250}{125} = 50 \text{ ohms.}$$

Duplicate cables, when in good repair, should be periodically looped and tested, in order to keep a record of the position of the "resultant fault," as a correction can then be applied to the determined position of an actual fault. With the high resistance faults now prevalent this correction should be applied

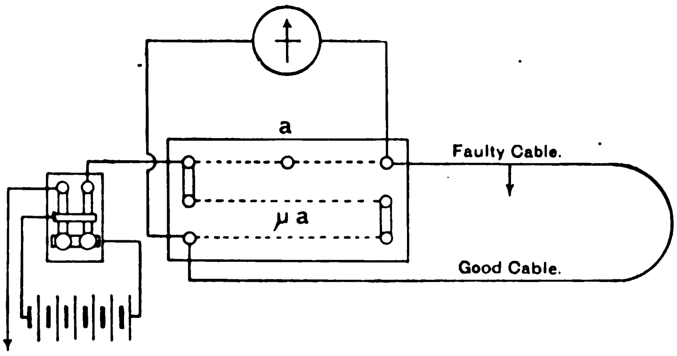

Fig. 126.—Murray Loop.

where possible. Kempe embodies this correction in the following formula* :—

$$\text{True distance of fault} = \frac{\beta P - a I}{P - I},$$

where β = distance in ohms of fault, as determined in ordinary way by loop test,
a = distance of resultant fault from same end of looped cables,
P = insulation resistance of looped cables at the time resultant fault was determined,
I = insulation resistance as lowered by presence of fault.

The above may be simplified by calling n the ratio of $\frac{P}{I}$, when true distance of fault $= \frac{\beta - a}{n - 1}$ ohms.

For example, suppose the resultant fault to be 3,200 ohms distant, and the apparent distance of the fault determined by the loop to be 2,700 ohms ($\beta - a = 500$); also that the insulation was 1,185,000 ohms at the time the resultant fault was determined, and 100,000 ohms when the fault came in. Then $n = 1{\cdot}185$, and true distance $= \frac{500}{0{\cdot}185} = 2{,}740$ ohms. In looped cables of perfect or uniform insulation throughout, the resultant fault is situated in the centre, where the cables are joined; but when a fault is present the location of the resultant is shifted from the centre towards the faulty side.

45. Tests of Cable in Tank.—After a repair there are a number of short lengths to be spliced up and tested. The piece containing the fault is coupled up to the test room, and the position of fault located. The faulty piece is then cut out, labelled, and kept for reference. The measurements on these short lengths are very low, and consequently low resistances have to be used in the bridge arms for the various free and earth tests described above. The loop test is specially applicable to the location of faults in short pieces, and the following two methods have been devised to give conditions of maximum sensitiveness.

Mr. Kingsford has proposed a second observation of the Varley loop, with cable ends reversed (*The Electrician*, Vol. IX). The connections are the same as in Fig. 125, using a bridge ratio of 10/1,000. The first observation gives

$$\frac{10}{1{,}000} = \frac{x}{A + y},$$

* "Handbook of Electrical Testing," p. 268.

and the second

$$\frac{10}{1{,}000} = \frac{y}{B + x},$$

where x is the distance in ohms to the fault from one end, y that from the other, and A and B the resistances unplugged to balance in each observation.

From the above expressions we have

$$x = \frac{100\,A + B}{9{,}999} \text{ ohms,}$$

and

$$y = \frac{B + x}{100} \text{ ohms.}$$

In J. J. Allen's modification of the Murray loop the usual places of the galvanometer and battery are interchanged, and

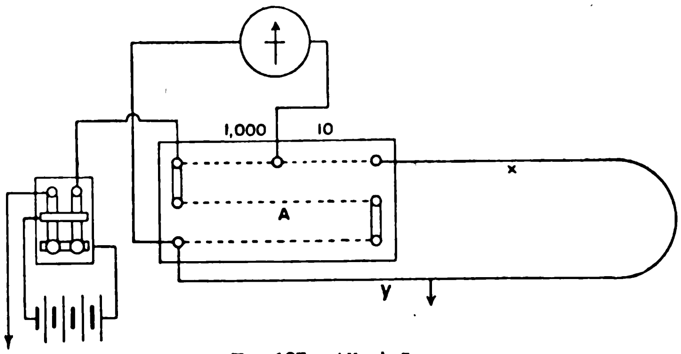

Fig. 127.—Allen's Loop.

a ratio of 10/1,000 is used (*The Electrician*, Vol. XV., page 350). With the cable ends as in the illustration (Fig. 127) we have

$$\frac{x + 10}{1{,}000} = \frac{y}{A},$$

and on reversing the cable ends we have

$$\frac{y + 10}{1{,}000} = \frac{x}{B};$$

whence

$$x = \frac{10\,B\,(A + 1{,}000)}{1{,}000{,}000 - A\,B},$$

and

$$y = \frac{(10 + x)\,A}{1{,}000}.$$

Cable coiled in a tank possesses self-induction—that is, a magnetic field is set up within the coils upon a current being sent through the cable, which retards the starting, stopping, or

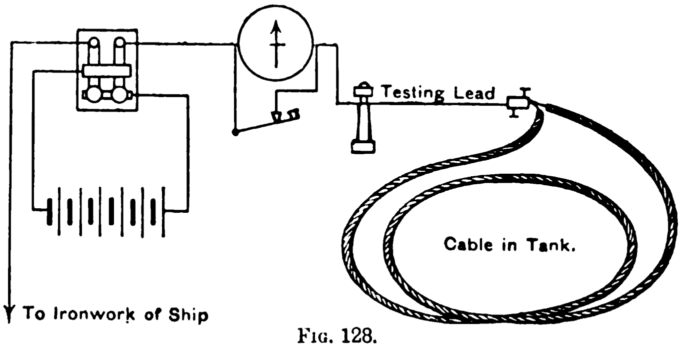

Fig. 128.

any change in strength of that current. This field is set up in all straight wires and cables through which currents are passed; but, as is well known, the magnetic effect is inappreciable and negligible. When the cable is coiled, however, the magnetic field is intensified by every turn of the cable, and also by the iron of the tank. The effect on the bridge is that, when first the current is applied, the resistance measured appears higher than its true value, because the E.M.F. of self-induction opposes the current like a resistance. As the current is kept on the opposing E.M.F. gradually falls to zero, the current rising the while to its full value. It is therefore necessary to wait till the current has been on for a few seconds, especially when testing long lengths, before finally

Digitized by Google

adjusting the resistance to balance. Even if the correct resistance has been unplugged in the bridge, and then the current put on, and the galvanometer key opened too soon, the deflection will show "more resistance wanted." This deflection will, however, creep back to zero in a second or two.

The effect is just the opposite to that experienced with laid cables. There the electrostatic effect predominates, and the current on first being applied rushes into the cable (on account of its electrostatic capacity) with great strength, making the resistance appear less than it actually is. If the galvanometer key is opened too soon there is a deflection indicating "less resistance wanted." This deflection comes back to zero in a few seconds like that due to self-induction mentioned above, and in both cases the balance is only correct when taken some few seconds after the current has been on.

Another disturbing effect on board ship is the current set up in the cable in tank due to the rolling of the ship. This makes good copper resistance tests difficult to obtain, and it is next to impossible to obtain good results with discharge tests on cable in tank. In tanks on shore there is only the self-induction effect to take into account, which is completely got over by allowing a few seconds before opening the galvanometer as described above; but when the tank and cable are rolling about at sea there are disturbing currents produced in the cable due to its moving relatively to the earth's magnetic field. In fact, it is well known that cable in tank tests much steadier on shore than at sea.

When testing for insulation resistance the effect may be got over by the simple expedient of taking both ends of the cable to the bridge, as in Fig. 128. The current then enters the cable in opposite directions, and no magnetic field is produced, and there is also no self-induction.

(To be continued.)

POLYPHASE MOTOR CALCULATIONS.*

BY HERMANN CAHEN.

Practical applications of the three-phase current to motors has recently been very much extended; but, in spite of that, the theory still presents numerous deficiencies. This may, in a great measure, be assumed, that the practical experiences of alternate-current plants in many cases are directly to be transferred to the three-phase current. On the other hand, particular details are still wanting on finished plants, without which the completion of a theory cannot be carried out. The most modern works in this branch are those of Dr. Behn-Eschenburg (No. 13) and of A. Heyland (No. 41 of the *Electrotechnische Zeitschrift*, 1894). In the former work it is proved, as in many other works on the alternate current, that the purely analytical mode of reckoning leads to little obvious results. The second treats the problem in a purely graphical way. Here the survey of the results certainly leaves nothing to be desired; but an analytical treatment is only possible when the results are expressed in the most simple terms.

In the following we will, therefore, endeavour to combine both methods, as it were, together. The diagrams are to be used for the derivation of more simple and handy formulæ, which allow of a calculation of the proportions of work of the motor.

We assume that all variables follow the sine law, and apply the following expressions:—

p_1 = Frequency of the exciting current (equal to the angular speed of the rotary field).
p_2 = Angular speed of the armature.
c_1 and c_2 = Number of spools of the exciting and armature systems respectively.
w_1 and w_2 = Number of windings in each spool of the exciting and armature systems respectively.
r_1 and r_2 = Resistance of one spool of the exciting and armature systems respectively.
E_1 and E_2 = Total electromotive force of the exciting and armature systems respectively.
I_1 and I_2 = Current of the exciting and armature systems respectively.
W_1 and W_2 = Supplied and useful energy respectively.
V_1 and V_2 = Loss in the exciting and armature systems respectively.
N_1 and N_2 = Number of lines of force of the exciting and armature systems respectively.
$E = w_1 p_1 N_1$ = Induced counter-electromotive force in the exciting current.
S = Angle of lag between E_1 and I_1.
$\frac{\pi}{2} + \psi$ = Angle of lag between I_1 and I_2.
L_1 and L_2 = Coefficients of self-induction.
M_1 and M_2 = Coefficients of mutual induction.
$\gamma = \frac{W_2}{W_1}$ = Efficiency of the motor.
z = Torque of the motor.

L_1 and M_1 shall be so defined that an exciting polyphase current, I_1, produces a rotary field equal to $\frac{L_1}{w_1} I_1$ lines of force in the exciting system, and equal to $\frac{M_1}{w_1} I_1$ lines of force in the armature. (In the same way L_2 and M_2.)

Then the following relations occur:—

$$L_1 : L_2 = c_1 w_1^2 A_1 : c_2 w_2^2 A_2.$$
$$M_1 : M_2 = c_1 : c_2.$$
$$M_1 M_2 = (1 - \sigma) L_1 L_2.$$

Here σ has a value which depends upon the waste field, while A_1 and A_2 are determined by the construction of the motor and only differ very little from each other.

In the following we may put approximately $A_1 = A_2$, and regard the values L, M and σ as constant.

The rotary field caused by the current I_1 and having the angular speed p_1 induces in the armature a polyphase current with the period $p_1 - p_2$. The latter produces in the armature a rotary field with a speed $p_1 - p_2$, and if we add to this the speed p_2 of the armature, we shall again get p_1 as the resulting speed for the induced rotary field.

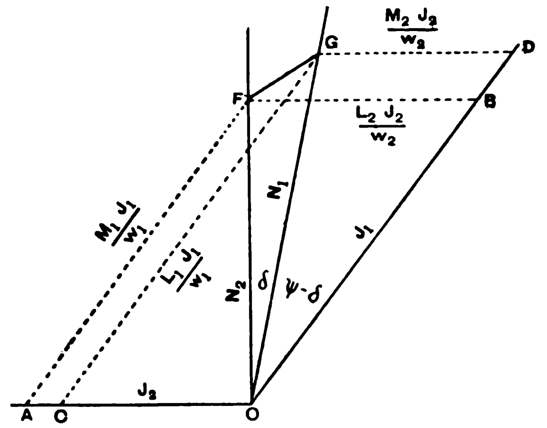

FIG. 1.

Both fields, which rotate with the same velocity, adjust themselves to the actual existing field. The latter consists, therefore, of:—

(1) The number of lines of force N_1 in the exciting system; (2) the number of lines of force N_2 in the armature, and (3) the waste field $N_1 - N_2$.

Fig. 1 shows the diagram for these expressions. In the diagram it is as follows:—

$$O A = \frac{L_2 I_2}{w_2}$$

and

$$O B = \frac{M_1 I_1}{w_1},$$

$$O F = N_2;$$

further

$$O C = \frac{M_2 I_2}{w^2} = O A \sqrt{1 - \sigma},$$

and

$$O D = \frac{L_1 I_1}{w_1} = \frac{O B}{\sqrt{1 - \sigma}},$$

$$O G = N_1,$$
$$O F = N_2,$$
$$F G = N_1 - N_2.$$

If we call the angle between N_1 and N_2 δ, we shall still get the following references—

$$\tan \psi = \frac{(p_1 - p_2) L_2}{r^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

$$\tan \delta = \sigma \tan \psi \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

$$\frac{N_2}{N_1} = \cos \delta \sqrt{1 - \sigma} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

The rotary field in the armature is then, owing to the loss of lines of force, distorted in reference to the exciting field as much

* From the *Electrotechnische Zeitschrift*, January 24, 1895.

Digitized by Google

as δ. The introduction of the angle δ contributes much to the simplification of the formulæ.

Fig. 2 shows in a well-known way the decomposition of the exciting E.M.F. E_1 in the induced counter E.M.F. $E = p_1 w_1 N_1$ and $I_1 r_1$. We take from this the references of the so-called "empty current" (or "wattless current") and the useful current (or "watt current"). The first falls with the direction of the lines of force N_1 together, whilst the second stands perpendicular to it.

Wattless current:

$$I_1 \cos(\psi - \delta) = \frac{E_1}{r_1} \cos(\psi - \delta + \phi).$$

Useful current:

$$I_1 \sin(\psi - \delta) = \frac{M_2}{L_1} I_2 \cos \delta = \frac{c_2 w_2 N_2}{c_1 w_1 N_1} \cdot I_2.$$

(Refer to (3).)

By aid of these references, the proportions of work of the motor are represented as follows:—

The energy to be spent for the overcoming of the counter E.M.F. in the exciting system is

$$c_1 p_1 w_1 N_1 \times \text{useful current} = c_1 p_1 w_1 N_1 I_1 \sin(\psi - \delta),$$

that would be, according to the former,

$$= c_2 p_1 w_2 N_2 I_2.$$

The last expression then represents all the quantity of energy absorbed by the armature.

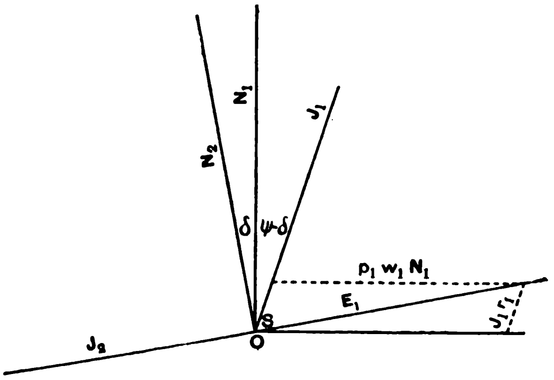

FIG. 2.

The heat in the armature due to the current is

$$c_2 E_2 I_2 = c_2 (p_1 - p_2) w_2 N_2 I_2.$$

If we subtract the latter from the supplied energy, the useful mechanical effect remains equal to

$$c_2 p_2 w_2 N_2 I_2.$$

The above, put together, gives:—

1. Supplied energy:
$$W_1 = c_1 E_1 I_1 \cos \phi.$$
2. Loss in the exciting system due to the current heat:
$$V_1 = c_1 I_1^2 r_1.$$
3. To the armature-system transmitted energy:
$$W_1^1 = c_1 (E_1 I_1 \cos\phi - I_1^2 r_1) = c_2 p_1 w_2 N_2 I_2.$$
4. Loss in the armature, due to current heat:
$$V_2 = c_2 I_2^2 r_2.$$
5. Useful energy:
$$W_2 = c_2 p_2 w_2 N_2 I_2.$$

Through a simple transformation of these formulæ, we get

$$\frac{W_1^1}{W_1} = \gamma' = \tan(\psi - \delta) \tan\phi,$$

$$\frac{W_2}{W_1^1} = \gamma'' = \frac{p_2}{p_1},$$

and, consequently, the efficiency of the motor:

$$\frac{W_2}{W_1} = \gamma' \gamma'' = \gamma = \frac{p_2}{p_1} \tan(\psi - \delta) \tan\phi. \quad . \quad . \quad . \quad (4)$$

Expressed in words: The relation between the loss in the armature, due to the heat, and the energy transmitted to it, is equal to the slipping of the motor, *i.e.*,

$$\left(= \frac{p_1 - p_2}{p_1}\right).$$

The last is most important, because it is to be applied for any polyphase motor with changeable permeability and hysteresis. In order to prove this, we regard the useful work of the motor to be a product of the angular speed p_2, and the torque Z (referred to the radius = 1). These are determined from the electrical and magnetic properties as follows:—

Let us consider the rotary field, which rotates with the velocity p_1 to be stationary, whilst the armature revolves with the velocity $(p_1 - p_2)$. Hereby must not only the same torque take place as in the motor, but the electrical and magnetic phenomena are the same. The heat V_2 produced in the armature, coming from currents or magnetic friction, is in all cases equal to the mechanical energy, which is able to turn the armature against the torque Z with the velocity $(p_1 - p_2)$; thus

$$V_2 = (p_1 - p_2) Z.$$

Now $\qquad W_2 = p_2 Z.$

thence, $\qquad \dfrac{V_2}{W_2} = \dfrac{p_1 - p_2}{p_2}$

as above.

Hence, it is at the same time proved that for any polyphase motor the efficiency must always be less than $\frac{p_2}{p_1}$.

If we call the loss due to hysteresis H, we get as a general valid formula

$$\gamma = \frac{p_2}{p_1} \cdot \frac{W_1 - I_1^2 r_1 - H}{W_1}. \quad . \quad . \quad . \quad . \quad . \quad (5)$$

For the experimental determination of γ, only one watt-meter and one ampere-meter are needed, because we only need to know H approximately, which can be calculated from the dimensions and properties of the iron.

We had for the useful energy

$$W_2 = c_2 p_2 w_2 N_2 I_2,$$

or after some transformations

$$W_2 = p_2 \frac{c_1 w_1^2}{L_1} N_1^2 \frac{\sin 2\delta}{2\sigma} (1 - \sigma).$$

Thus for the torque

$$z = \frac{c_1 w_1^2}{L_1} N_1^2 \frac{\sin 2\delta}{2\sigma} (1 - \sigma) \quad . \quad . \quad . \quad . \quad . \quad (6)$$

We can now, as may be shown further on, for good motors with constant tension at the terminals, also consider N_1 to be constant. Then the torque will have its maximum when $\delta = 45$deg. If we denote the maximum value by z_m, then we will get for another load,

$$\frac{z}{z_m} = \sin 2\delta \quad . \quad . \quad . \quad . \quad . \quad . \quad (6a)$$

Hence $\sin 2\delta$ represents the magnitude of the torque.

It remains now to observe the different expressions in their relation to the velocity p_2.

When running light, p_2 is only a little smaller than p_1. Thus ψ and δ are very small. I_1 would, in the diagram, theoretically fall nearly together with N_1 and N_2. In reality the difference is, owing to hysteresis, considerably larger.

ϕ is approximately equal to $\frac{\pi}{2}$.

If the load increases, p_2 decreases, ψ and δ increase in proportion

$$\frac{\tan\delta}{\tan\psi} = \sigma;$$

therefore δ increases more rapidly than ψ. The angle ϕ decreases at first, until it is a minimum at about normal load, although it is to be noticed that it never can be so small as in an alternate-current transformer, where, as it is known, ϕ, from a certain load, is practically equal to 0. A polyphase motor will always cause a noticeable lag between the volts and current, and this occurs on account of the proportionately large angle δ of the waste field.

We will now examine more closely these relations, with examples. For that purpose we observe the motor at the following characteristic loads:—

1. Light running.
2. The efficiency γ is a maximum.
3. The efficiency γ^1 of the exciting spools is a maximum (see equation (4)).
4. The lag between E_1 and I_1 is a minimum, *i.e.*, $\cos\phi$ is a maximum.
5. The useful work W_2 is a maximum.
6. The torque z is a maximum.
7. Starting.

For these seven loads we get the following values of $\tan\psi$, the derivation of which we leave out; it must, however, be observed that these are only theoretical values, *i.e.*, the losses in the iron are not taken into consideration:—

1. Light running:
$$\tan\psi_1 = 0.$$
2. γ = maximum:
$$\tan\psi_2 = -\frac{1}{\mu} + \sqrt{\frac{1}{\mu^2} + \frac{p_1 L_2}{r_2} \cdot \frac{1}{\mu}},$$

where $\qquad \mu = p_1 \left\{ \frac{L_2}{r_2} + \frac{L_1}{r_1} (1 - \sigma) \right\}.$

Digitized by Google

3. γ' = maximum:

$$\tan\psi_3 = 1.$$

4. Cos ϕ = maximum:

$$\tan\psi_4 = \frac{1}{\sigma}\cdot\frac{r_1}{p_1 L_1} + \sqrt{\frac{1}{\sigma^2}\cdot\left(\frac{r_1}{p_1 L_1}\right)^2 + \frac{1}{\sigma}}.$$

5. W_2 = maximum:

$$\tan\psi_5 = -\frac{1}{\sigma^2}\cdot\frac{r_2}{p_1 L_2} + \sqrt{\frac{1}{\sigma^4}\cdot\left(\frac{r_2}{p_1 L_2}\right)^2 + \frac{1}{\sigma^2}}.$$

6. z = maximum:

$$\tan\psi_6 = \frac{1}{\sigma}.$$

7. Starting:

$$\tan\psi_7 = \frac{p_1 L_2}{r_2}.$$

For all seven occurrences, of course, after formula (1) there holds:—

$$\tan\psi = \frac{(p_1 - p_2) L_2}{r_2}.$$

These seven equations now show a constant increasing of $\tan\psi$ from 0 to the maximum value $\frac{p_1 L_2}{r_2}$. In reality, however, the values of $\tan\psi$ in the readings (1) and (2) have another position. For the light running, $\tan\psi > 0$, due to the friction in the bearings. Further, after formula (2) $\tan\psi_2$ must always be smaller than 1, and this corresponds, as will be seen from figures further on, to a small load. Thus, the influence of the inner and outer friction is proportionally large, causing the value of γ to be reduced, so far that (2) nearly coincides with (4). The other formulæ only change a little, so that we get, as a rule, for a useful motor, that the load (4) is the normal, and further that the maximum load (5) shall not be too far from the latter, as then the decreasing of the efficiency and of $\cos\phi$ would be too great. Finally, it is desirable, but not always necessary, that the torque at the starting be not too small.

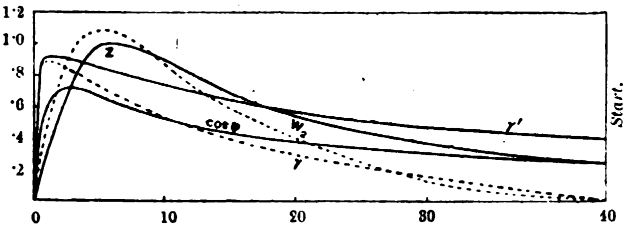

Fig. 3.

The last point is most simply obtained. Namely (formula (6a))

$$\frac{z_7}{z_m} = \sin 2\delta_7,$$

and (formula (2))

$$\tan\delta_7 = \sigma\tan\psi_7 = \frac{\sigma p_1 L_2}{r_2}.$$

If we now suppose that σ is limited between 0·2 and 0·4, it is easy to calculate how great $\frac{p_1 L_2}{r_2}$ must be in order that at starting the torque is a certain part of the maximum torque. If, for for example, it be equal to the maximum torque, so must

$$\tan\delta_7 = 1,$$

and

$$\frac{p_1 L_2}{r_2} = \frac{1}{\sigma}\ (=5 \text{ to } 2{\cdot}5).$$

It is now easy to show that such a consideration would lead to a very unpractical motor, as we know that the efficiency γ is always smaller than $\frac{p_2}{p_1}$. If we now suppose that the normal load coincides with (4), *i.e.* (cos ϕ equal to maximum), and we consider that generally speaking

$$\frac{p_2}{p_1} = 1 - \frac{\tan\psi}{\tan\psi_7},$$

then we shall get for the normal load

$$\frac{p_2}{p_1} = 1 - \frac{\tan\psi_4}{\tan\psi_7}.$$

Now (4) shows that approximately

$$\tan\psi_4 = \frac{1}{\sqrt{\sigma}}.$$

Thus we should get for the normal load

$$\gamma < 1 - \sqrt{\sigma}$$
$$< 0{\cdot}55 \text{ to } 0{\cdot}37.$$

With the object of getting a good efficiency, the torque at starting must not be too large. We now see from this that the state of the motor in reality is determined from both expressions σ and $\frac{p_1 L_2}{r_2}$. Still more distinctly is this to be seen from the following curves (Figs. 3 and 4). These are constructed on a free assumed scale and for the following relations:—

Fig. 3:

$$\sigma = 0{\cdot}17, \quad \frac{p_1 L_2}{r_2} = 43{\cdot}6, \quad \frac{p_1 L_1}{r_1} = 30{\cdot}8.$$

Fig. 4:

$$\sigma = 0{\cdot}24, \quad \frac{p_1 L_2}{r_2} = 30{\cdot}8, \quad \frac{p_1 L_1}{r_1} = 30{\cdot}8.$$

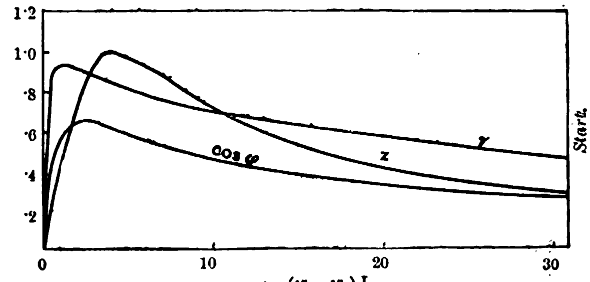

Fig. 4.

For the construction of the curves, a free-chosen value of $\tan\psi = \frac{(p_1 - p_2) L_2}{r_2}$ is at first taken.

Then it was successively placed:

$$\gamma' = \frac{1}{1 + \left(\frac{r_1}{p_1 L_1}\right)\frac{1 + \tan^2\psi}{(1-\sigma)\tan\psi}};$$

$$\frac{p_2}{p_1} = 1 - \left(\frac{r_2}{p_1 L_2}\right)\tan\psi;$$

$$\gamma = \frac{p_2}{p_1}\gamma';$$

$$\tan\delta = \sigma\tan\psi;$$

$$z = z_0 \sin 2\delta;$$

$$\cot\phi = \frac{\tan(\psi - \delta)}{\gamma'};$$

$$\frac{p_1 w_1 N_1}{E_1} = \frac{E}{E_1} = \frac{\sin\phi}{\cos(\psi - \delta)}$$

The values of the loads 2, 4, 5, 7, are now collected as follows:

Fig. 3.

—	2 γ = max.	4 cos ϕ = max.	5 W_2 = max.	7 Starting.
$\frac{p_2}{p_1}$	0·98	0·94	0·88	—

$\frac{E}{E^1}$	0·99	0·95	0·93	0·93

Fig. 4.

—	2 γ = max.	4_1 cos ϕ = max.	5 W_2 = max.	7 Starting.
$\frac{p_2}{p_1}$	0·98	0·93	0·88	—
tan ψ	0·76	2·18	3·68	30·8
tan δ	0·18	0·52	0·87	7·41
γ'	0·91	0·90	0·86	—
γ	0·69	0·84	0·75	—
cos ϕ	0·49	0·65	0·62	0·30
sin 2δ	0·35	0·82	0·99	0·25
$\frac{E}{E_1}$	0·99	0·96	0·95	0·96

In the diagrams two kinds of curves are distinguished. The first (γ', z, and cos ϕ) are full lines, these are not affected from

Digitized by Google

the position of the starting line; the second sort (γ, W_2 and W_1, shown dotted) depend mostly upon this. If the starting line is shifted to the left, then the torque at starting is larger, but the efficiency for normal load smaller (*i.e.*, $\cos\phi$ = maximum). At the shifting to the right, the contrary takes place. In both diagrams the assumption was, that the torque at starting was a quarter of the maximum; this seems still to be too much for the attainment of a good efficiency. The torque at starting is, however, due to hysteresis, in reality a little larger.

Fig. 5 shows the curves of Fig. 3 to an enlarged scale, and embraces about that part which comes into question when using the motor.

The hysteresis changes the curves, especially in the beginning. γ is, as already noticed, somewhat lowered, and reaches the maximum value later than theory dictates. The values of $\cos\phi$, on the contrary, are, especially in the beginning, somewhat larger. The maximum load coincides nearly with the maximum torque.

The tables explain the influence of σ. It is true that, at an increasing waste field, $\cos\phi$ is smaller in relation to the efficiency, whilst, on the contrary, the torque at normal load increases. This is to be seen in the diagrams from the approaching of the normal and maximum loads.

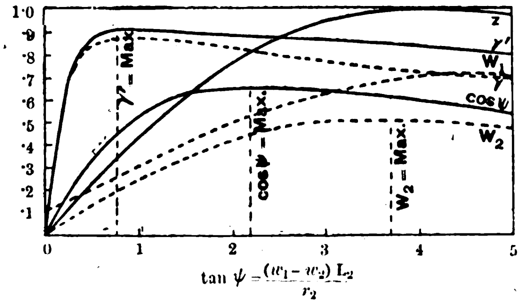

FIG. 5.

We will now describe an approximate way of fixing the lapse of the curves for any motor in advance. By this we only take into consideration the normal, maximum, and starting load.

In the first approximation we may now say:—

For the normal load, $\tan\psi = \frac{1}{\sqrt{\sigma}}$,

For the maximum load, $\tan\psi = \frac{1}{\sigma}$.

[NOTE.—This expresses in reality the maximal torque. If for the starting $\delta = \delta_\gamma$, then it is for the maximum load

$$\tan\psi = \frac{1}{\sigma}\tan(\tfrac{1}{2}\delta_\gamma)$$

to produce a high efficiency; δ_γ is, as a rule, nearly equal to $\frac{\pi}{2}$.]

For the starting load, $\tan\psi = \frac{p_1 L_2}{r_2}$.

We get, on this supposition, for the normal load

$$\gamma' \cot\phi = \frac{1-\sigma}{2\sqrt{\sigma}}$$

and

$$\frac{z \text{ norm.}}{z \text{ maxim.}} = \frac{2\sqrt{\sigma}}{1+\sigma}.$$

In the following table these values are put together:—

$\sigma =$	0·1	0·2	0·25	0·3	0·35	0·4
$\frac{z \text{ norm.}}{z \text{ maxim.}} =$	0·56	0·75	0·80	0·84	0·88	0·90
$\gamma' \cot\phi =$	1·42	0·895	0·75	0·64	0·55	0·475
i.e., for γ' = 0·9 respectively for γ' = 0·8						
$\cos\phi =$	0·85	0·71	0·64	0·58	0·52	0·47
$\cos\phi =$	0·87	0·75	0·70	0·62	0·57	0·51

Since the efficiency is always smaller than γ', we see that a motor with a waste field $\sigma > 0·1$ already works under bad conditions, because either ϕ is too great or γ' too small. (In regard to this, the so-called one-phase motors are somewhat more profitable.)

We will now, by the aid of these formulæ, calculate a polyphase motor, which will produce normally 10,000 watts at an E.M.F. of 200 volts (eff.) and 50 periods. Thus,

$$W_2 = 10{,}000.$$

Experience teaches that by using machines of this type an efficiency of

$$\gamma = 0·83$$

and a coefficient of waste field

$$\sigma = 0·2$$

may be expected. The absorbed energy is thus

$$W_1 = \frac{W_2}{\gamma} = 12{,}000.$$

The motor may be constructed with two poles. The velocity is then

$$p_1 = 2\pi \,.\, 50 = 314.$$

In reality, we should choose about six poles for this; the method of calculation is, however, the same.

We assume now $\gamma' = 0·9$

if we allow 2 per cent. for hysteresis and friction, and 5 per cent. for slipping, thus:—

$$\frac{p_2}{p_1} = 0·95.$$

The former table shows now that for $\gamma' = 0·9$ and $\sigma = 0·2$,

$$\cos\phi = 0·71.$$

We now get the current

$$I_1 = \frac{\frac{1}{3} W_1}{E_1 \cos\phi} = 28·2 \text{ amperes (eff.)},$$

and the resistance

$$r_1 = \frac{E_1}{I_1}\cos\phi\,(1-\gamma') = 0{,}505\ \Omega.$$

Now we have

$$\gamma' = \frac{1}{1 + \left(\frac{r_1}{p_1 L_1}\right)\frac{1+\tan^2\psi}{(1-\sigma)\tan\psi}};$$

thus, in our example, as $\tan\psi = \frac{1}{\sqrt{\sigma}}$,

$$\frac{p_1 L_1}{r_1} = \frac{1+\sigma}{(1-\sigma)\sqrt{\sigma}} \cdot \frac{\gamma'}{1-\gamma'} = 30·3,$$

$$L_1 = 0·048 \,.\, 10^9.$$

We get, further, from Fig. 1

$$w_1 N_1 = L_1 I_1 \frac{\cos\psi}{\cos\delta},$$

or, as we here have

$$\tan\psi = \frac{1}{\sqrt{\sigma}} \text{ and } \tan\delta = \sqrt{\sigma}$$

$$w_1 N_1 = L_1 I_1 \sqrt{\sigma} = 0{,}615 \,.\, 10^8.$$

We had, of course, been able to find this value direct from the formula

$$p_1 w_1 N_1 = E_1 \frac{\sin\phi}{\cos(\psi - \delta)}.$$

We get a controller for the calculation in the expression

$$p_1 w_1 N_1 = E,$$

as this is only allowed to differ from E_1 a few per cent. In fact

$$p_1 w_1 = N_1 = 193.$$

The last formulæ have only a partial practical value, as it may be impossible to determine with sufficient accuracy the dimensions of the iron frame from the expressions L_1, r and $w_1 N_1$ in connection with a supposed permitted induction (about 4,000 to 8,000). This occurs still more in the construction of the armature. We, however, can always get a datum about the relation $L_1 : L_2$.

From

$$\tan\psi = \frac{(p_1 - p_2) L_2}{r_2}$$

we have

$$\frac{p_1 L_2}{r_2} = \frac{1}{\sqrt{\sigma}} \cdot \frac{p_1}{(p_1 - p_2)} = 44·7.$$

This is, however, to be considered as an entirely approximate value; as if the slipping, for instance, changes only 1 per cent., then the changing of $\frac{p_1 L_2}{r_2}$ already reaches 20 per cent.

We get a better datum if we consider the torque at starting. This may be one-fifth of the maximum, or (as the normal torque is 0·75 of the maximum) equal to 0·27 of the normal.

Thus it is for starting,

$$\sin 2\delta = 0·2,$$

$$2\delta = 168°$$

(2δ must, of course, lie in the second quadrant),

$$\delta = 84°,$$

$$\frac{p_1 L_2}{r_2} = \tan\psi = \frac{1}{\sigma}\tan\delta = 44·6.$$

As this differs only 6 per cent. from the former calculated value, this consideration is in agreement with the above. If we had arrived at a more serious difference, we should have been obliged to calculate the motor afresh, for a slipping, corresponding to the new value.

For controlling, the expressions for the motor at maximum load are now to be determined.

Digitized by Google

The results obtained thus far are as follows :—

$$W_1 \max = 16{,}500 \text{ watts},$$
$$W_2 \max = 12{,}000 \quad ,,$$
$$I_1 = 43{\cdot}7 \text{ amp.},$$
$$\gamma' = 0{\cdot}825,$$
$$\gamma = 0{\cdot}725,$$
$$\frac{p_2}{p_1} = 0{\cdot}88,$$
$$\cos\phi = 0{\cdot}63.$$

Besides, we get the current at starting

$$I_1 = 63{\cdot}5 \text{ amp},$$

and $\cos\phi = 0{\cdot}25.$

Thus, the absorbed energy at starting

$$W_1 = 9{,}500 \text{ watts}.$$

By this example I hope to have proved the usefulness of the formulæ.

ELECTRIC WELDING IN BOILER REPAIRS.

Speaking in the discussion of a Paper on "The Application of the Electric Arc to Machinery and Boiler Repairs," which was read a short time ago at the North-East Coast Institution of Engineers and Shipbuilders, by Mr. Henry Foster, Mr. Mountain gave some interesting and useful particulars of this branch of electrical industry. The Bernardos process, he considered, was handicapped by the heavy royalty charged by the firm now holding the patents, but he stated that this firm were now offering very much more favourable conditions. From his own experience he had found for welding, or in other words, melting up defects in steel castings, and also for repairing forgings, &c., that it was impossible to do good work with a current of less than 300 amperes, and to cope with whatever work might crop up in a steel foundry he considered that the dynamo should be capable of giving 500 amperes at the very least. He was quite sure if dynamos of this size were used instead of the machines for 100 or 150 amperes, which were put down in some of the steelworks in Sheffield and elsewhere, that they would not hear of the defects in the heating which were so frequent. If a small machine giving a current of only, say, 150 amperes, were used, it was impossible to get sufficient heating effect to more than just locally heat the spot where the current was applied; but having a larger current the heat was spread all round the defect, with the result that a solid weld or melt was obtained. In Sheffield he saw an attempt being made at a works, to whom his firm had supplied a welding plant, to weld up the defects in a stern frame with their old plant, which gave 100 amperes, and they might just as well have applied a match as attempted welding satisfactorily with the arc they obtained from the machine. He attempted some time since to weld up boiler flues prior to flanging, and they had a great difficulty in getting the steel to stand the flanging, as it was apparently to some extent burnt; and he gave a statement of some actual tests made upon welded wrought-iron boilers for greenhouses and for domestic purposes. The object in conducting these tests was to be able to ascertain whether the process was likely to supersede hand welding and the table would be interesting inasmuch as it gave pretty conclusively the length of steel which could be welded at a time, together with the time occupied in doing it.

Result of Tests made on June 11, 1892, in welding two Steel Boilers; thickness of steel, ⅜in.

Volts at battery.	Volts at arc.	Current in amperes.	Time of each heat.	Length heated in inches.
			Min.	
130	...	370	2	2
115	...	400	1½	3
120	...	350	1½	3
115	...	350	1¼	2½
113	75	350	1½	3
115	85	350	1½	3
118	65	250	1¼	2
122	85	300	1¼	2
122	85	350	1½	3
122	75	250	1½	last weld

Total length welded, 100in. in 85min., 1in. in 51sec.

Iron 5/16 thick.

116 ... 75 ... 300 ... 45sec. ... 2½

These tests proved pretty conclusively that to weld a steel plate ⅜in. thick required a current of not less than 300 to 350 amperes, whereas prior to the experiments being made it was considered that a current of 100 amperes could be employed.

He thought that some distinction should be made between what might be called electric melting and electric welding. To melt, it was only necessary to have an electromotive force of about 75 volts at the dynamo terminals, and of course a resistance must be placed in circuit to steady the arc; but to weld—that is to say, to join together two pieces of rolled or hammered steel or iron—it was necessary to have an electromotive force of 115 to 120 volts, and to have a very long arc, which could be used in the same way as a blow pipe, the arc being rapidly moved over the surface of the plate, so that it was not allowed to impinge for any length of time on one spot and melt the metal. He had found this to be necessary in connection with the plant which he supplied for electric welding of barrels, and the results had been very satisfactory. From his own experience he could most unhesitatingly state that if electric welding plants were made large enough, that is to say, that the current per arc was not less than 350 to 400 amperes, very excellent work could be done, and there was no doubt that the defects welded up in steel castings or in forgings repaired in this manner were a thoroughly good job; but it was nearly certain that when electrical plants were put down too small for the work a proper adhesion was not obtained between the casting and the piece of steel melted into it, and they then heard of the bad work that had caused this process to be condemned to a great extent by the Admiralty, &c.

THE JONAGE CANAL ELECTRIC SUPPLY WORKS.*

This undertaking was declared officially to be of public utility in the year 1893. A concession was granted for the carrying out of the works to the Société Lyonnaise des Forces motrices du Rhône, and the realisation of the enterprise had for its object the distribution in the city of Lyons and its suburbs of a force of 20,000 H.P. This powerful motive force was obtained at Cusset-Villeurbaune by drawing upon the resources of the Rhône. At the Exhibition of Lyons visitors had the opportunity of inspecting a plan in relief of the Jonage Canal, and numerous designs and drawings of the different works in connection with the whole scheme. It was M. I. Raclet, an engineer well known in Lyons, and the administrator of La Société Lyonnaise, who planned out the general lines and distinctive features of this important work. By the cut or deviation of a part of the Rhône at Jons, not only is the navigation improved, but a fall is provided near the Grand-Camp, which is capable of supplying to the industry of Lyons a minimum force 12,000 H.P. Many attempts had been previously made to establish canals of irrigation in connection with the Rhône on the up-stream boundaries of Lyons, but opposition founded, rightly or wrongly, upon the injury to the navigation, had always been too strong for them and their promoters. But the Jonage scheme, instead of injuring the navigation, greatly improves it for a distance of at least 10 miles, and maintains that portion of the river in a navigable condition the whole year round, even when the water is at its lowest. In an industrial point of view the great water power of the Rhône has been—similarly to the neglect of our own rivers—very little used in France, but in Switzerland, the town of Geneva, with a population of only 70,000, has very materially utilised a deviation or small branch of the same river in obtaining a fall affording a force of 2,500 H.P. The total length of the new Jonage cut is 11½ miles, and comprises three distinct parts. The first, or supply canal, takes off from the left bank of the Rhône opposite Jons. At this point in its course the river has a slight bend, and the levels of the bed of the river and of the bed of the canal have been so adjusted that all silting up will take place in the direction of the river channel and not in that of the canal. The discharge or escape canal has a total length of a couple of miles, and the width of both the supply and the discharge canal is nearly 200ft. About half way along the canal a compensating reservoir, containing a million and a-half tons of water, has been constructed. It possesses the especial advantage of always maintaining the water of the canal at a fixed level, so that if at any time the turbines threatened to lower the water level of the canal, a fresh supply would immediately flow in from the reservoir, and compensate for any slight temporary deficiency.

Among the more important works which characterise this enterprise now in progress, may be included the dam which regulates the discharge of the canal. At low water the minimum volume amounts to 22,500 gallons per second, which can be augmented to 33,750 gallons, when the supply from the Rhône equals 135,000 gallons. The dam consists essentially of a protective wall, having a total length of 456ft. The height of the wall is 33ft., and it is 8ft. wide at the top, which is carried up to a level of 3ft. above high water. In the dam itself circular openings are constructed, which are fitted with sluices of a circular section for the purpose of regulating the delivery. The apparatus for working the sluices is placed on the top of the wall. Attached to the wall of the dam is a lock, which at high water provides for a difference of level of

* Abstract from the *Engineer*.

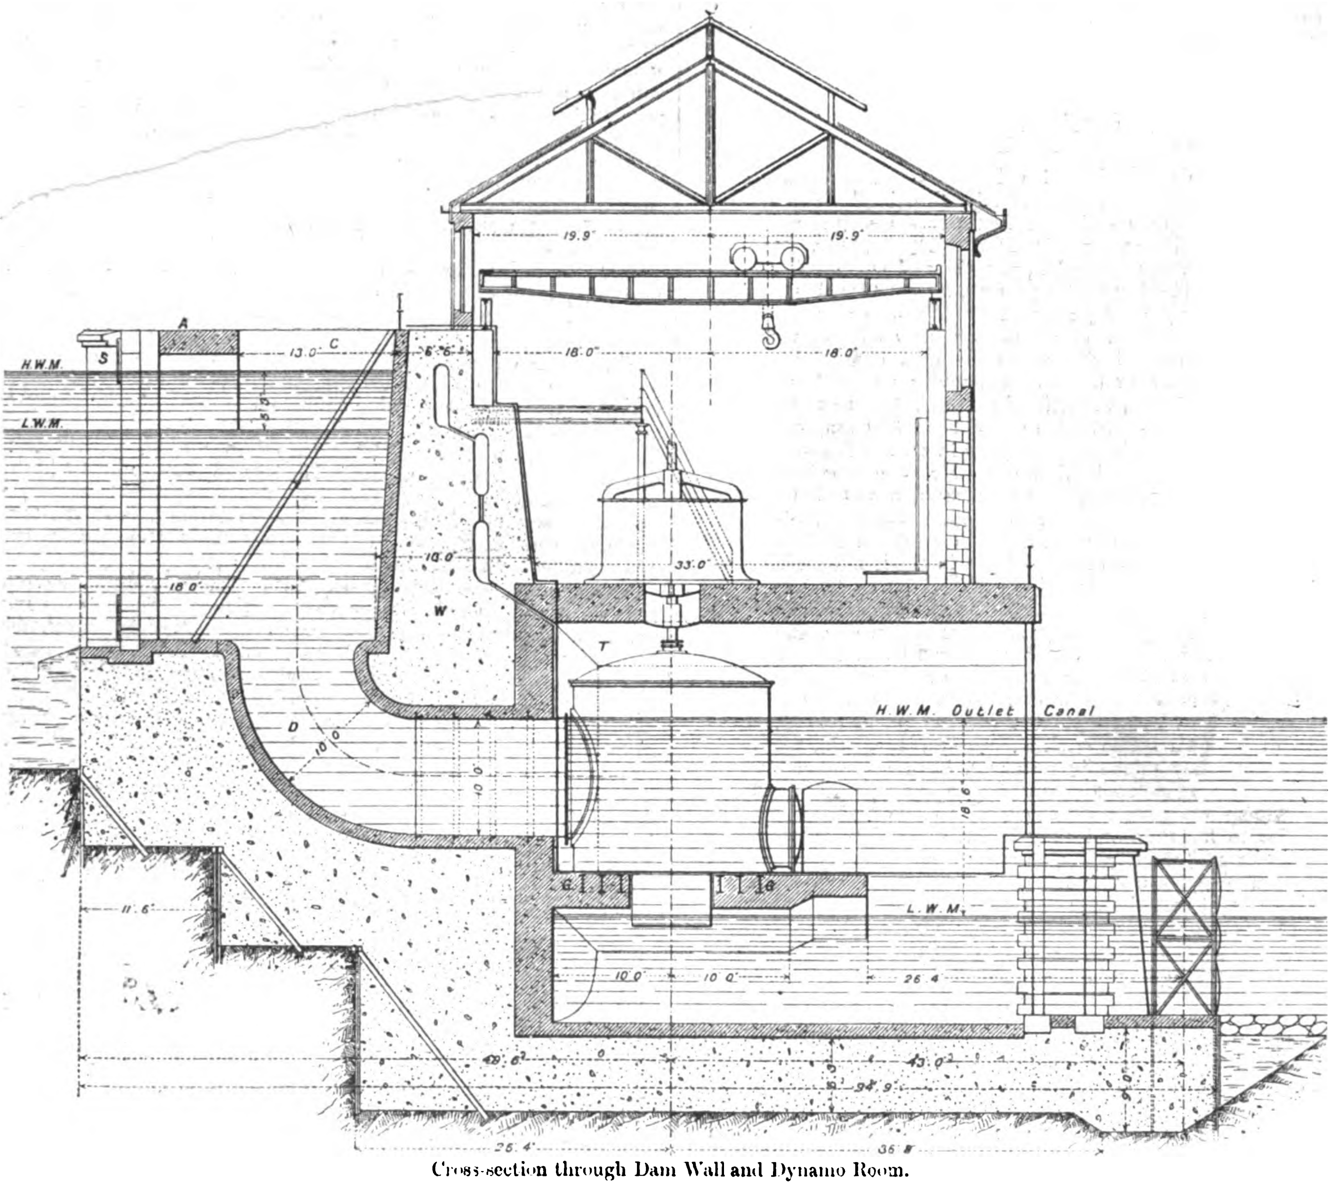
13ft. between the up and down stream faces of the work under notice.

The contract for the works was divided into two sections, one being allotted to MM. Vigner et Roux, and the other to MM. Audhert, Alméras et Jubin. On both sections the operations are carried on with the greatest activity. Dredgers and excavators are hard at work, and a couple of branch lines connect the site with the railway to Lyons, and bring the materials on the ground. Under ordinarily favourable conditions, the contractors expect to complete their engagements in the early months of 1897.

Another work in connection with this undertaking is of equal importance with that already described. It consists of a dam wall, the installation of dynamos, turbines, and the arrangements for collecting the water power, transmitting and utilising it. The installation provides for the employment of 20 units of 1,000 H.P. each. It consists chiefly of a retaining wall, which collects the water which passes into the turbine chambers. This wall abuts against the building wherein the turbines and dynamos are placed, as represented in the figure by W. In it are built the collecting or receiving chambers or recesses C. This figure is a cross-section through both the dam wall and dynamo building. The form of the water chambers in plan is semi-elliptical, and the face slightly battered. These chambers are separated from one another by solid projections or buttresses, 10ft. in thickness, and terminating in the face of the wall by cutwaters or starlings. From cutwater to cutwater is thrown a series of arches, A, built of cement béton, 6ft. 6in. in width and 1ft. 8in. in thickness. Besides helping to strengthen the wall these arches serve to provide a footbridge along the whole length of the dam. In front of these arches chases are cut in the ashlar work to receive the gate or door frames. A solid foundation 40ft. in width has been provided for the wall, and in it are constructed conduits D of bent form. They have a diameter of 10ft. internally, and serve to convey the water, which they receive through a horizontal inlet from the receiving chambers C into the turbine chambers T by a vertical outlet as shown in the figure. The turbine chambers are arched, and are each 18ft. in width and 34ft. in extreme height, and are separated by partition walls 8ft. 4in. thick. Between these partition walls spring the arches which support the turbines, and to render them perfectly secure they are further strengthened by iron girders laid in the body of the masonry and marked G.

Above the turbine chambers is erected the building in which the dynamos are situated, represented in cross-section in the figure. It has a width of 33ft. at floor level, and a total length of 528ft. The dynamos and turbines are adjusted in position in such a manner that the shaft of each separate turbine is connected with and works only its corresponding dynamo. Upon the left bank of the canal are the repairing shops, which are connected with the installation buildings, as are also the houses for the accommodation of the staff and workmen. All the arches, partition walls of the turbine chambers, the backing of the wall and the lining of the conduits are built with cement concrete. Cut stone has been used in both the up-stream and down-stream façade of the machinery building, and dressed ashlar for the grooves or recesses in the buttresses and starlings. In the wall itself on the up stream side of the houses ordinary masonry is employed.



Cross-section through Dam Wall and Dynamo Room.

On the right bank of the canal, close to the installation works, there is a double lock similar in design and construction to that already described, and of the same dimensions. By means of this lock a difference of water level in the supply and outlet canals of 29ft. 6in. is obtained at high water, and of 37ft. at low water. The intake of the bent conduit pipe in the receiving chambers is placed at a level of 17ft. 9in. below that of low water in the upper or supply canal, and the total height of the whole building in which the machinery is housed is 94ft. from the bottom of the foundation trenches to the bridge. The director of the works is M. A. Gotteland, Engineer-in-chief of the Ponts et Chaussées.

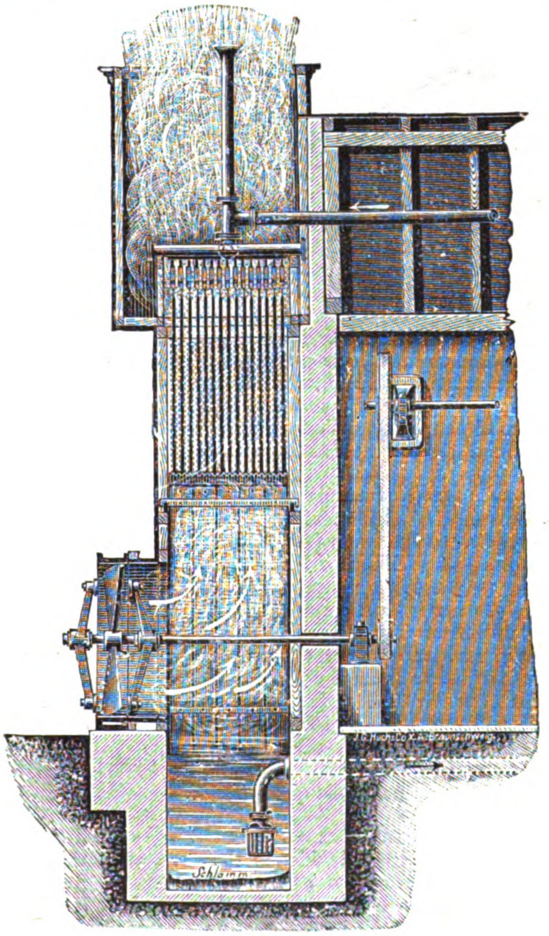
A CONDENSING WATER COOLER.

Klein's cooler for cooling condensing water in a very cheap way is a new apparatus introduced into this country by Mr. E. Larsen. As will be seen in the accompanying illustration, the apparatus consists of a number of wooden plates hanging side by side; and when the water is pumped to the top of the apparatus it will by a very simple arrangement flow slowly down over the extensive surface of the plates and, by the forced or natural draught of air through the apparatus, be cooled not only to the temperature of the air, but, because of a slight evaporation during the process, even as much as 20deg. below this temperature. It will thus be seen that by help of these coolers it is possible to use the same condensing water over and over again. The condenser vacuum can be kept on 25-27in., and the coolers can be worked as well for jet condensers as for surface condensers. Of course, a higher vacuum could be



obtained, but this would not be in good proportion to the cost. Some results from actual working may be of interest, and are given below :—

—	Deg.	Deg.	Deg.
Temperature of air	86	68	46
„ heated water	122	113	107
„ cooled water	77	71	63

It will be understood that this is not the lowest possible degree of cooling in these cases, but it is sufficiently low cooling for condensing purposes. The apparatus makes it possible (the same water always being used) to use any amount of condensing water without increasing the water bill very materially. To show results obtained for low cooling the following are results taken from actual working :—

—	Deg.	Deg.	Deg.
Temperature of air	86	68	46
„ hot water	71	68	60
„ cooled water	59	53	39

Where room is scarce the coolers can be worked with a fan attachment, in which case they take up much smaller space for the same effect than with natural circulation. These coolers have been constructed up to very large dimensions, and the largest working is cooling water from steam engine of 3,000 H.P. At one place on the Continent, where the apparatus is at work, for some time the weekly consumption of water was, it is said, reduced from 1,125,000 gallons to 80,000 gallons, equal to a saving of not less than 1,045,000 gallons per week, and at 6d. per 1,000 gallons this would be equal the £26 weekly.

THREE-PHASE PLANT AT WINOOSKI, VT.*

The Westinghouse three-phase power plant which has been installed for the Vermont Electric Company, Winooski, Vt., for supplying the city of Burlington with electric power, presents many points of interest. The electrical equipment of the power house consists of a Westinghouse generator, rated at 46 amperes at 2,500 volts, running at 450 revolutions per minute, and having a periodicity of 7,200 alternations. The machine over-compounds 10 per cent. at full load. It has 16 poles, with drum-wound slotted armature, and triangle construction for three-phase work. It can be belted direct from a turbine, or from a countershaft, which is in turn driven either by a turbine or steam engine. The exciter is driven from the shaft of the generator.

The transmission line, which is $2\frac{1}{2}$ miles long, consists of No. 0 weather-proof insulated wire. There is also, covering the principal business part of the city, a secondary network of No. 0 wire. The primaries are run on white glass insulators; the secondaries on green glass.

The secondary mains are fed by two banks of transformers in parallel, each bank consisting of two $18\frac{3}{4}$-kilowatt transformers installed in a brick vault. One vault, out of doors, has a removable tin-covered roof, and is provided with a trap door from which all the fuses may be reached. There are fuses on both the primary and secondary side of this vault. The second vault, which is located in the basement, is similar to the first, except that it has the primary fuses on a pole outside of the building. Both vaults are perfectly ventilated, and each has space for a third transformer when the load shall require it.

The motors are three-phase, with "cage"-wound revolving secondary and distributed primary windings. They are driving printing presses, elevators, and various manufacturing machinery. The service is excellent, and the demand for power is rapidly increasing. A large number of small industries in Winooski rely entirely on the electric power supply, and more than 100 H.P. in small motors is already connected to the set of secondary mains. Many motors in distant parts of the city have individual transformers. At present the transformation is effected by two instead of three transformers in a bank. Each motor has a fuse cut-out, a three-jaw switch, and a Shallenberger recording wattmeter. The local company and consumers have arranged to instal a meter at each motor, even when several motors are used by the same customer. It is proposed to equip another set of secondary mains in different districts of the city before long.

THE BROOK-GREEN INCANDESCENT LAMP WORKS.

We have recently had an opportunity of visiting the works of the Incandescent Electric Lamp Company, at Brook-green, London, W., where the "Robertson" glow lamp is manufactured at a rate, it is said, of from 3,000 to 4,000 per day. The Company took the works over in 1893, and commenced to erect the extensive plant necessary to maintain the present output, and at the same time to allow a considerable margin for a probable increase. The vacuum and compressed air services comprise many miles of tubing and accessories; and the installation generally, and the education of the hands, occupied a considerable time before the works could be said to be productive. This latter work was rendered necessary by the fact that the Company determined to employ British labour, and, as the construction of the "Robertson" lamp is peculiar to itself, a course of training was essential. Whatever experience in lamp making was possessed by some of the hands was useless, since the industry has practically been at a standstill in England since the establishment of the monopoly in 1888.

The factory is situated in the north-west corner of Brook-green, W., and consists of a large four-storied block, with special lighting arrangements; and, where the more risky operations are carried on, the floors and ceilings have been rendered fireproof. Immediately in front of the building there is a large courtyard and a roadway from Brook-green, at the entrance of which are the stores, offices, and a caretaker's residence. The whole of the

* Abstract from the *Electrical Engineer*, of New York.

Digitized by Google

steam and electric generating plant, furnaces, engines, accumulators, carpenters' shop, and supplementary store-room are situated in the basement of the building, from which run the ramifications of the various installations. The electric services are led up to the switch room, which is on the first floor, in the centre of the works. From this point distributing wires are laid to the various departments, and, owing to the continual changing over and adjustment required, an attendant is always on duty, who is in telephonic communication with the engine room and the various other departments. Systems of roughing vacuum, fine vacuum, and air pressure for the blowpipes, &c., are also distributed throughout the workshops, the final or finishing vacuum being made *in situ* by a set of mercurial pumps.

The "Robertson" lamp is the invention of Mr. C. J. Robertson, who is the general manager of the works. Mr. Robertson possesses a unique experience in the practical manufacture of incandescent lamps, having commenced in the Lane-Fox department of the Anglo-American Brush Company, in charge of the testing room. Since that period he has assiduously followed the subject in a practical manner, and has studied on the Continent at some of the best works. The lamp which is the outcome of of this long and varied experience at home and abroad is different in structure, but not in appearance, from other lamps by other makers. The filament is prepared originally in a liquid form from a carbon-containing solution, and is then squirted through orifices under high pressure. The filament, after baking, possesses a brilliant surface, and will scratch glass. It is mounted in the grooves of the platinum conductors by what is known as the "burning-in" process, which consists in the deposition of carbon by electricity from an atmosphere or fluid containing carbon, the junction being heated by the passage of a current. The bulbs of the Robertson lamp are made of special crystal glass, and are blown in a mould to ensure each being exactly alike.

We were particularly struck with the spacious and comfortable accommodation which is afforded the employés at these works, especially in regard to the cleanliness and good ventilation of the workshops. We understand that upwards of 130 hands are regularly employed here, and in almost all the departments the work is undertaken largely by girls.

DEPENDENCE OF THE PHOTOELECTRIC CURRENT UPON THE AZIMUTH AND THE ANGLE OF INCIDENCE OF THE LIGHT.*

BY DR. J. ELSTER AND H. GEITEL.

After it had become evident that the intensity of the electric current started by illuminating the cathode in a rarefied gas depends upon the orientation of the plane of polarisation of the light with respect to the cathode surface,† we endeavoured to determine the particular conditions of this phenomenon. In this determination we followed the plan, indicated in the last Paper, of changing the angle of incidence as well as the azimuth of the polarised light.

The cathode employed was the sodium-potassium alloy used before, enclosed in a spherical exhausted glass vessel; the anode of platinum wire was fixed opposite. The vessels were 50mm. in diameter, and the size was chosen in such a manner that the surface of the alloy could be regarded as practically a plane surface in the middle. Perfect purity of the liquid metallic mirror is essential; an intense beam of light must not be reflected at all diffusively by the point of incidence; this point must remain perfectly invisible to the eye, which does not look along the reflected ray. The source of current employed was a battery of 100 to 400 zinc-sal-ammoniac-carbon elements with a total E.M.F. of 420 volts. The light was supplied by a small disc of zirconium rendered white-hot by an oxy-coalgas blowpipe flame. This was firmly clamped in the box of a magic lantern. The rays were collected by a condenser, made parallel by a second lens, and emerged into the darkened room. A beam of any smaller diameter could be picked out by means of a screen. The lantern was firmly connected with the lens and screen, and could be turned in a vertical plane without disturbing the arrangement of the parts, so that the ray could be given angles of 90° to 40° with the normal of incidence. Smaller angles of incidence were produced by reflection of the horizontal rays by a silver mirror movable about a horizontal axis. It was necessary to ensure that the ray of light always impinged upon the same point, viz., the centre of the cathode surface lying just under the anode point. In this case it is evident that the ray must cut the two walls of the spherical glass globe at equal heights before and after reflection. At these points the image of the slot on the glass (this was usually rectangular, with the longer side horizontal) was clearly recognisable, and the cell could be easily shifted, so that this image was at equal heights above the surface of the liquid metal on both sides. One of the cells, specially employed for verifications, we could just half fill with the liquid metal. When it was arranged in the manner indicated for the incident beam, the latter had to pass through its centre, and would, therefore, cut the glass surface perpendicularly at every point; hence the light incident upon the cell retained the same intensity for all azimuths of the plane of polarisation.

The current through the cell was measured by a scale-and-mirror galvanometer, taking care that the lamp serving to illuminate the scale was so distant as not to influence the cell.

If the beam of light, after passing through a Nicol prism, impinges upon the cathode surface at any angle exceeding zero, a periodically-varying current intensity is obtained on turning the prism, as in our previous experiments. The maxima are obtained when the principal section of the Nicol coincides with the plane of incidence, *i.e.*, when the plane of polarisation is perpendicular to the plane of incidence. The minima are obtained in a position normal to this. Designating the current intensity obtained in the first position by A, in the second position by B, and the angle through which the prism has been turned from the first position by a, the observed current intensity for every value of a may be expressed, within the limits of observational error, by the formula

$$J = A \cos^2 a + B \sin^2 a.$$

The angles of incidence below 40° were obtained, as described, by reflection from a silver mirror, the Nicol prism being introduced between mirror and cell. The method is in this case less accurate owing to a slight elliptical polarisation of the light reflected from the mirror. A rotation of the Nicol would therefore in itself produce a change of intensity in the transmitted light, and hence a corresponding change in the current intensity. We found, however, by photometric measurements, that this source of error has little influence in comparison with the inevitable variations of the zircon light. To eliminate these variations, the first position was returned to after each series of measurements, and only such series were retained as did not show a decided change in the light intensity.

According to our previous experiments the intensity of the electric current is, under similar conditions, proportional to the luminosity, *i.e.*, to the square of the amplitude. Hence the above formula simply implies that this ratio is different for light polarised in a plane perpendicular and parallel to the plane of incidence respectively. Let a be the amplitude of the polarised light, whose plane of vibration (not of polarisation) makes the angle a with the plane of incidence, then the amplitudes in the plane of incidence and normal to it are $a \cos a$ and $a \sin a$ respectively, and the intensities $a^2 \cos^2 a$ and $a^2 \sin^2 a$. If x is the ratio for the first, y for the second position, the total current intensity is

$$J = a^2 x \cos^2 a + a^2 y \sin^2 a,$$

and the ratio $\frac{x}{y}$ is given by the quotient $\frac{A}{B}$.

In general, the values of $A = a^2 x$ and $B = a^2 y$ are different; only with a vanishing angle of incidence they are, of course, identical. The former rapidly increases at first with increasing angle of incidence, until the latter attains about 60°, after which it decreases. B steadily decreases with an increasing angle of incidence, so that at an angle between 60° and 65° the ratio A : B becomes about 50 : 1.

The accurate determination of the angle for which the maximum current is generated by light polarised perpendicularly to the plane of incidence, is attended with great difficulties, chiefly due to variations in the intensity of the light. Hence the values found for this angle vary between 58° and 66°.

We consider it very probable that the higher photoelectric efficiency of the light polarised in a plane perpendicular to the plane of incidence is connected with the fact discovered by Herr Quincke,* that such light penetrates with much greater intensity in metallic layers than that polarised parallel to the plane of incidence.

If we regard a beam of natural light as composed of two beams polarised at right angles to each other of half the total intensity, it follows that, with the decidedly stronger photoelectric effect of the component normal to the plane of incidence, natural light must also show a maximum of current intensity at an angle of about 60°. This conclusion is confirmed by experiment.

It is natural to suppose that this angle of incidence near 60° is also the angle of polarisation of the sodium-potassium alloy for the electrically active, especially the blue rays. We have endeavoured to apply the method used by Knoblauch in his investigations concerning the elliptic polarisation of heat rays to this photoelectric determination. We allowed light polarised at an azimuth of 45° to fall upon the sodium-potassium surface, and to impinge vertically upon the solid sodium cathode of a photoelectric cell after reflec-

* Sitzungsberichte der Akad. der Wissenschaften, Berlin, XI., p. 209, 1895.

Digitized by Google

tion, and after it had passed through a second Nicol prism. This latter cell, therefore, only served for the measurement of the luminosities transmitted through the second Nicol, and took the place of the thermo-element used in the corresponding experiment with heat rays. From the luminosities found for the various azimuths of the second Nicol, the axes and the position of the ellipsis of vibration of the light reflected by the sodium-potassium surface could be determined by Knoblauch's method. The angle of polarisation could then be recognised by the fact of the ratio of the axes most closely approaching unity, while the direction of the major axis is normal, and of the minor axis parallel to the plane of incidence. The experiment proved that these characteristics appeared at an angle of about 65°, but it must be noted that this is also only a rough approximation. There seems, however, to be no contradiction to the supposition that the maximum of photoelectric current occurs with light polarised normally to the plane of incidence when the beam impinges upon the cathode at the angle of polarisation.

The results of this investigation may be summed up as follows :— If a is the azimuth of the polarised ray, counted from the position in which the plane of polarisation is perpendicular to the angle of incidence, and where, therefore, the electric displacements take place in the plane of incidence ; and if A and B are the intensities of the photoelectric current for $a=0$ and $a=90°$ respectively, the current intensity may be generally represented by the formula—

$$J = A\cos^2 a + B\sin^2 a.$$

A and B depend upon the angle of incidence. Except for the angle of incidence zero (for which A = B), A is always larger than B, and grows with the angle of incidence, until the latter, at about 60°, approaches the angle of polarisation, perhaps becomes identical with it, after which it decreases. B always diminishes with increasing angle of incidence, and appears to approach zero at skirting incidence.

With natural light there is also a maximum of photoelectric current with an angle of incidence about 60°.

All these results refer to the natural free surface of the sodium-potassium alloy, consisting of equivalent proportions of both, which is liquid at ordinary temperatures.

LEGAL INTELLIGENCE.

Kirsopp v. Hunter and Jack.

At the Linlithgow Sheriff Court the record has been closed in an action brought by Messrs. Hunter and Jack, electrical engineers, of St. Vincent-street, Glasgow, against Mr. Henry Kirsopp, of Bathgate, for £36. 4s. 7d., as balance for fitting up an electric light installation and supplying certain fittings incidental thereto in defender's premises. The defender raised a counter action for £34. 7s. 3d. in respect of loss and damages sustained through the breaking of a bracket on which one of the electric lamps was suspended, and pleads that in February, 1894, the pursuers contracted to complete an electric light installation in his premises at Bathgate, to be fitted up and left working to the satisfaction of the pursuer. In April, 1894, the defenders asked permission to put up, at their own expense, two small arc lamps outside pursuer's shop. This permission was given, and two Richardson arc lamps were put up, these being suspended from cast-iron brackets fitted into the wall. Some time after the pursuers asked the defender to take over the arc lamps, offering them at cost price. This was agreed to on the understanding that the lamps should be made to work satisfactorily. The lamps did not prove satisfactory, the light given being intermittent, and after several complaints the defenders agreed to replace them by two arc lamps of a different make. The Richardson lamps were taken away in October, 1894. On December 1st the defenders put—suspended from the same brackets—two new arc lamps of a different make, and very much heavier than the former lamps. In January last, when current was switched on, one of the cast-iron brackets from which the lamps were suspended broke, with the result that the lamp fell until caught by the wire carrying the current. The accident was due, it was alleged, to the carelessness of the defenders or to their foreman who superintended the installation, and for whose fault they are liable. The bracket was quite insufficient to bear the weight of the heavier lamp, and this should have been known to the pursuers. At the time of the damage injury was inflicted upon three persons who were looking into the shop windows, and the pursuers denied liability. Mr. Kirsopp paid £30 in settlement of the damages advanced by the injured persons, at the same time notifying Messrs. Hunter and Jack that he held them liable. This settlement was, it was contended by Mr. Kirsopp, a reasonable compromise of the claim for damages, and the pursuers were accordingly bound to repay the sum of £30 and also the sum of £4. 7s. 3d., the cost of replacing the plate glass window broken by the fall of the lamp, and Mr. Kirsopp retained the balance of the installation account pending the settlement of the claim.

Messrs. Hunter and Jack, in reply to the counterclaim, state that in order to contribute to the success of the inaugural ceremony of switching on the electric light and to increase the spectacular effect, offered to loan the two lamps, and that offer was accepted. The lamps were fitted up temporarily, and the cast-iron brackets were supplied by Mr. Kirsopp. Subsequently Mr. Kirsopp offered to purchase the lamps, and they accepted his offer. Subsequently they exchanged the said lamps for two others—known as "Solar" arc lamps—and these were suspended to Mr. Kirsopp's brackets. Having supplied the lamps they had nothing to do with them after, and no guaranty or warranty was given to Mr. Kirsopp. The brackets were lengthened by Mr. Kirsopp without consultation with them, and were subsequently removed to another point by Mr. Kirsopp without notice to them. The brackets were therefore, they plead, not part of their contract.

Fell v. Whittaker.

In the Ambleside County Court, Westmorland, last week, before Judge Steavenson, Messrs. R. H. Fell and Son sued Mr. Edward Whittaker, of Windermere, for the sum of £5. 6s. 9d. for the repair of damage caused by the breaking of a glass globe used in the plaintiffs' electric lighting system. A glass globe placed on the top of one of the lamp-posts between Windermere and Bowness was broken by an employé of the defendant. No notice had been given to the plaintiffs of the breakage, and their person in charge of that section of the installation had turned on the current at the usual time. After doing so, he found there was something wrong, and ultimately discovered the broken globe. Owing to the breakage of the glass, the rain was admitted, and prevented the current passing the lamp, with the result that the increased current had damaged several other lamps between it and the switch house. The defendant wrote the plaintiffs asking the amount of damage done. It was contended that the items put in the particulars were the direct consequence of the breaking of the globe, and that the plaintiffs were entitled to damages.

Mr. TILLY, for the defendant, submitted that the plaintiffs were without parliamentary powers, and really had no business to place the lamps in the position where the accident occurred. Before an action could be brought for the damage they must, he contended, prove they had a right to be there.

His HONOUR held that it was a serious thing if, by accidentally breaking a glass globe, a man was liable to pay £5. 6s. 9d., and asked why the plaintiffs could not have the lamps inspected immediately prior to turning on the current. For the plaintiffs it was contended that they had the necessary rights. They had utilised the old gas lamp-posts, and had an agreement with the Local Authority for the supply of power.

His HONOUR said there was no evidence produced that the lamps were lawfully there, and the objection taken by the defendant was right.

Judgment for the defendant.

Bocquet v. Frank Suter and Co.

In the Chancery Division, before Mr. Justice Romer, last week, the plaintiff in this action sued the defendants for carrying on processes known as "dipping" and "lacquering," from which fumes of a noxious and poisonous character were given off, and claiming an injunction to restrain the defendants from a continuance or repetition of the damage to her premises from the fumes, and also damages in respect of the nuisance complained of. It was explained that the defendants occupied premises immediately below those of the plaintiff.

Mr. Justice ROMER said a nuisance was caused to the plaintiff by the nitric acid fumes, and the defendants must stop that nuisance either by giving up the "dipping" process altogether, or taking further precautions. An injunction restraining the nuisance referred to, the defendants to pay the costs of the action, was granted.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

SPECIAL NOTICE.—The 1895 (thirteenth) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. In addition to the old well-known features of the book, which are brought up to date, a quantity of new and useful matter has been added, rendering the book more than ever indispensable to the Electrical, Engineering, and Allied Trades. Price, 7s. 6d., post free 8s. 3d., abroad 9s.

*The following New Books and Editions of "*THE ELECTRICIAN*" SERIES can be obtained of the Booksellers or direct from the Publishing Offices :—*

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett (*now ready*). Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

Digitized by Google

A Large-Sheet Table, giving full particulars of the Electricity Supply Stations throughout the Kingdom, can now be supplied mounted on stout board, with cord for hanging. Price: Varnished, 3s. 6d.; Unvarnished, 3s. —each post free. A Map showing positions of Supply Stations throughout the country is mounted on the back of the Table, and a Coloured Map of Metropolitan Electric Lighting Areas and a large sheet of Electricity Supply Statistics are also mounted on some copies, the price of which complete, post free, is 5s.

"Electro-Chemistry."—This useful work, by Dr. G. Gore, is still on sale, the price being 2s., post free.

"The Electrician."—A special notice concerning certain changes in the price, &c., of this journal will be found on page 262.

Tenders Invited.—The Electric Lighting Committee of the Corporation of St. Helens (Lancs.) invite tenders for the supply and erection of boiler and engine-house plant, switchboard and instruments, underground work (including cables, boxes, culverts, &c.), transformers and fittings, meters, and overhead crane for their electric lighting station. Tenders are to be sent in to Mr. W. J. Jeeves, Town Clerk, Town Hall, St. Helens, not later than Tuesday, July 2nd.

——— The Electric Light Committee of the Bedford Corporation invite tenders for the supply and erection of water-tube boilers, engines, and alternators. Tenders to Mr. T. S. Porter, Town Hall, Bedford, by Tuesday next, the 25th inst.

——— The Urban District Council of Clevedon require tenders for the public lighting of their district every night in the year from sunset to midnight. Tenders are to be for one, two, or three years, and must be sent in to Mr. H. C. Fry, Clerk of the Council, Clevedon, by July 1st.

——— The Corporation of Blackburn invite tenders for the wiring of the Town Hall. Tenders must be sent in by July 13th.

——— The District Committee of the Lanark County Council invite tenders for the electric lighting of the new hospital at Motherwell. Tenders must be sent in to Mr. J. F. Mackenzie, County-buildings, Hamilton, by July 1st.

——— The Belgian State Railway authorities invite tenders for the supply and erection of dynamos, switchboards, conductors, posts, lamps, &c., for the electric lighting of the railway station, carriage and waggon shops, and the locomotive shed at Schaerbeek-Nord, Brussels. Tenders must be addressed to the Administration des Chemins de Fer de l'Etat Belge, the Bourse, Brussels.

——— Tenders are invited until the 6th prox. by the General Direction of French Posts and Telegraphs for the supply of two lots of paper-insulated electric cables. Tenders must be sent in to the Direction Générale des Postes et des Telegraphes, 103, Rue de Grenelle, Paris.

Tenders Accepted.—In our issue of May 31st particulars were given of several tenders accepted by the Hanley Town Council for plant and apparatus for electric lighting extensions. In addition to the contract secured by Messrs. W. H. Allen, Son and Co. for surface-condensing apparatus at £755, and for two Lancashire boilers and fittings by Mr. E. Danks, of Oldbury, at £1,178, tenders have been accepted from the British Insulated Wire Company for high and low-tension cables for £1,393. 8s. 4d., from the Brush Electrical Engineering Company for transformers with high and low-tension switches for £632. 2s., from Messrs. S. Z. de Ferranti for switchboard, &c., at £252. 10s., and from the Stanton Iron Company for 2in. cast-iron pipes at £4. 12s. 6d. per ton. The Council's decision as to the tenders for arc lamps and posts was deferred to the next meeting.

——— The Brighton Town Council, on the recommendation of the Electric Lighting Committee, have finally accepted the tender of Messrs. Hart, Son, Peard and Co. (Limited), of Birmingham and London, for the supply and delivery of 80 cast-iron and drawn-steel bracket posts for arc lamps for £2,600, of which notice was given in our issue of May 17th.

——— The Tunbridge Wells Town Council have accepted the tender of Messrs. Laing, Wharton and Down, for wiring and fitting up the municipal buildings for the electric light.

——— The Ayr Police Commissioners have accepted the tender of the Callender Company for electric cables for the extensions authorised at a recent meeting of the Commissioners, and which was referred to in our last issue.

Sales by Auction.—In July, Messrs. Fairbrother, Ellis, Clark and Co. will dispose of the patent rights and the goodwill of the business of the Wenham Company (Limited) at Upper Ogle-street, Fitzroy-square, London, W. The lease of the extensive factory and premises, with engines, boilers and fixed plant, will also be offered for sale early in July.

——— Mr. Wooller Jennings has been instructed by Mr. James Duff, the Receiver and Manager of Andrews and Preece (Limited), to sell by auction, at the Borough Mills, Manchester-road, Bradford, on Wednesday, July 3rd, at 11 o'clock, the whole of the valuable plant of engineers' tools and effects, stock-in-trade, &c. Detailed catalogues can be obtained seven days before sale from Mr. Jennings, 66, Thornton-road, Bradford. Some further particulars appear in our advertisement columns.

Appointment Vacant.—The Governors of the Northern Polytechnic invite applications for the post of principal. After the 25th March next the stipend will be at the rate of £500 per annum, and from September 29th next to March 25th at the rate of £300 per annum. Some further particulars will be found in our advertisement columns, and applications must be sent in to Mr. E. Griffiths, secretary, St. Mary's Vestry Hall, Islington, N., before July 15th, on forms which, together with all further information, can be obtained at the Vestry Hall.

Appointment.—The Electric Lighting Committee of the Tunbridge Wells Town Council recommend that Mr. H. L. P. Boot, of Dublin, be appointed resident engineer at the Corporation's electricity works.

——— Mr. T. Hesketh, who is at present engaged by the Blackpool Corporation at their electricity works, has been appointed assistant electrician at Madrid by the Electricity Supply Company for Spain.

Removal.—On and after the 24th inst. Messrs. Clayton and Shuttleworth will remove their London offices and showrooms from 78, Lombard-street, E.C., to 95, Queen Victoria-street, E.C., where motors for electric lighting, pumping, sawing, &c., will be on show. These will include portable and fixed steam engines and patent oil and gas engines (in motion).

——— The County of London and Brush Provincial Electric Lighting Company (Limited) have removed from 49, Queen Victoria-street, E.C., to Moorgate-court, Moorgate-place, London, E.C.

Dissolution of Partnership.—Messrs. F. and A. Wright, who have hitherto carried on business under the style of Alexander Wright and Co., as electrical apparatus manufacturers, at 19 and 21, Old Queen-street, and Millbank-street, Westminster, London, S.W., have dissolved partnership. Debts by Mr. F. Wright, who continues.

Personal.—Mr. A. E. Evans, who has for same years past been connected with the International Electric Company, has severed his connection with that firm, and has started in business as accountant and auditor at London-road, Romford, Essex.

Bankruptcies.—In the failure of J. T. Todman, electrician, a composition offer has been submitted by the debtor, which is to be discussed at a meeting shortly to be called.

Liquidation.—On May 9th it was resolved that the Johannesburg Lighting Company (Limited) be wound up voluntarily, and Mr. J. Taffs, 54, St. Mary-axe, London, E.C., was appointed liquidator.

——— A summary of the liquidator's accounts is issued in respect of the winding-up of the London Metallurgical Company (Limited), from which it would appear that a balance of £737. 9s. 1d. is in the liquidator's hands for disbursement.

——— A summary of the liquidator's accounts in Poole and White (Limited) is issued showing a balance of £520. 19s. 11d., after payment of Board of Trade and court fees, incidental outlays, &c.

Madras Electric Tramways Company (Limited).—On the calling of the petition of the Commercial and Land Mortgage Bank for the winding-up of this Company, it was stated that the debt had been paid, and leave to withdraw the petition was sanctioned by Mr. Justice Romer.

Exports of Telegraph Wire and Apparatus.—The value of exports of telegraph wire and apparatus connected therewith from this country during May only reached £26,942, as compared with £90,077 in May last year. The returns for the first five months of the year amounted to £126,688, against £542,095 in the corresponding period of 1894.

Pearson's Automatic Fire Indicator Company (Limited).—This Company has entered into an agreement with E. Mann, electrical engineer (referred to as the vendor) for the transfer to the Company of the vendor's rights in the invention of R. Pearson for a thermometric circuit closer used for a fire alarm, and the right to the patent which has been applied for in connection with the same, pursuant to the Provisional Protection No. 5,650 (1894), and the right to take up and apply for patents for the said invention in any of the British colonies and dependencies and in foreign countries. The consideration for the transfer is fixed at £2,000, payable £1,000 in cash and £1,000 by the allotment of 1,000 £1 fully-paid shares in the Company.

The "Hunningscone" Microphone Transmitter (Deckert Patent, No. 21,565).—We have received the following from the General Electric Company (Limited):—

"As it has come to our knowledge that certain manufacturers of microphone transmitters are adopting the name of our transmitter, known as the 'Hunningscone,' and are advertising their own wares under this title, with the result that some of our customers have been thereby imposed upon, we beg to offer the following explanation:—We are the

Digitized by Google

originators of the name 'Hunningscone' as a name for Hunning's transmitter, and that name was suggested by the fact that the internal construction of our transmitter necessitated the use of a number of cones or pyramids, arranged in a peculiar manner, to which is due (in conjunction with other details) the excellent effects obtained. This transmitter is manufactured to the Deckert patent, of which we possess the sole rights, and is the same as now used in large quantities by the General Post Office on their long lines, including the trunk lines recently opened between London, Glasgow and Dublin, and is also universally adopted by the National Telephone Company. Intending purchasers, therefore, would do well to be quite sure that they are obtaining the genuine article, manufactured to the Deckert patent specification otherwise they are not obtaining the original Hunningscone, but something which must necessarily be inferior or the manufacturers would not be pushed to such straits as to purloin a title for it. At the same time it speaks well for our transmitter that trade competitors should as a guarantee of excellence advertise their supplies under titles which have appeared in our catalogue for the last three years."

Argentina.—The *Review of the River Plate* says that electric lighting is making rapid strides throughout the country, and it will not be long before all the principal cities have adopted the light. Esperanza, in the Province of Santa Fé, is now lighted, and Quilmes is soon to be lighted, by electricity. Concordia is talking about adopting it, and several other municipalities are contemplating its adoption. The lighting of the important towns of Rosario and La Plata is given as a proof of complete success.

Association of Municipal and County Engineers.—The annual meeting of this Association takes place at Halifax on the 27th, 28th and 29th inst. The electricity works are to be visited on the 29th.

Beckenham (Kent).—At the last meeting of the Urban District Council a letter was read from the Crystal Palace District Electric Supply Company notifying a reduction of the Company's charges for electric current.

Bedford.—Major Tulloch, R.E., held a Local Government Board inquiry last week into the application of the Town Council for sanction to borrow £27,000 for electric lighting extensions. Opposition to the loan was offered by Mr. W. J. Jessop on the ground that the electric lighting was being carried on at a loss. The Mayor stated that the installation was most successful, and was supported in this statement by many leading members of the Corporation. With regard to Mr. Jessop's opposition, it was contended that the figures given by that gentlemen were altogether erroneous, and the opposition personal and against the interests of the ratepayers. The local gas company was unrepresented at the inquiry.

Board of Trade Revised Regulations.—The Edinburgh Town Council have appointed Mr. Mackenzie and Sir James Russell to lay the Council's views before the Board of Trade as to the regulations and conditions proposed to be made by that body for the public safety in connection with electric light installations.

Bolton.—In the electrical engineer's report presented to the Gas Committee of the Corporation last week it was stated that 67 consumers were taking current equivalent to 5,200 8 c p. incandescents. The whole of the contracts have been let for the extensions recently approved, and it was anticipated that the new plant would be ready for work by September next.

Bray.—The Town Commissioners, at their last meeting, considered a letter from Mr. S. G. Fraser on the subject of constructing an electric tramway from the railway station at Bray to Bray Head, and thence through the Putland property to the summit of the hill. Mr. Fraser points out that the poles for the overhead conductors could be utilised for the lighting of the route by electricity. In Mr. Fraser's opinion, the ascent of Bray Head by an electric tramway presents no serious engineering difficulties. At the same meeting a letter was read from the Earl of Meath, generously offering land in the route of the proposed tramline, and this offer and Mr. Fraser's letter were referred to a committee specially appointed to consider the whole subject.

Cape Town.—At a recent meeting of the Town Council of Cape Town the question of the electric lighting of the city was discussed, and it was stated by the Mayor that the original estimate of £75,000 had not been exceeded. It was decided to considerably increase the number of public lamps by a further 50 additional arcs, and it was also decided to put an arc lamp outside every place of worship in the city. Complaint was made that some of the street lighting was ineffective, but it was pointed out that a few initial difficulties had been met with which had been overcome by the contractors. An attempt to worry the officials responsible for the electric lighting of the city was unsuccessful.

Derby.—The Market Hall has recently been completely fitted for the electric light by Messrs. John Davis and Son, of All Saints' Works, Derby, and Newgate-street, London. The switching on ceremony took place last week. There are six 20-ampere arcs fitted for lighting the interior of the hall, and the approaches are also lighted by arc lamps. The stalls and shops are provided with incandescents, of which about 400 are fitted throughout the buildings. Special care has been given to the switchboard arrangements and safety devices, and by a simple arrangement of the meters the consumption of current can be taken for any of the various sections at a glance. Gas is, we understand, to be entirely superseded by the electric light.

Dundee.—The annual meeting of the Gas Committee of the Town Council was held on Wednesday to receive the accounts for the past year and the estimates for the ensuing year. Treasurer Ritchie stated that the revenue was £80,042. 10s. 4d. The expenditure, including the deficiency on the electric lighting department, reached £80,173. 11s. 2d., a deficiency of £131. 0s. 10d. This was due to the serious fall in the price of their gas residual products. Next year they anticipated to bring out a balance on the right side in connection with the electrical department, the estimated revenue being £4,400, while the estimated expenditure was £4,386. It was resolved that no change be made in the charges for electric current.

Edinburgh.—The Town Council have adopted the recommendation of the Electric Lighting Committee (mentioned in our last issue) to extend the mains to the Regent, Carlton, and Royal Terraces, South Back Canongate, George-square, and the south side of the city, at an estimated cost of about £5,000. Mr. Cranston asked if the committee had received the necessary guarantee, and Mr. Mackenzie said that from the people in the terraces they had more than the necessary guarantee, and in Clerk-street and George-square they had the same. The Committee considered the electric light was a success.

Electric Traction in America.—The Manhattan Elevated Railway Company has, it is stated, decided to substitute electricity for steam as the motive power on its road.

Electric Traction in France.—It is proposed to construct a tramway between Neris and Montencon, and a short railway line from Montaign to Moissac, Tarn-et-Garonne, the motive-power in both cases to be electric.

Fire.—An outbreak of fire occurred on Monday last at the premises of Messrs. New and Mayne, electrical engineers, 9, New Bridge-street, Westminster, S.W.

Fort William.—A meeting of gentlemen interested in the proposal to light this burgh by electricity was held on Tuesday last, Mr. R. Yorke, electrical engineer, of West Regent-street, Glasgow, attended, and gave particulars of the proposed scheme, which is receiving much local support, and a company is being formed to carry out the work. The promoters have been presented with the land through which the water from the River Nevis is to be taken, and negotiations are in progress for the acquisition of further land for erecting a turbine house.

The Gas Institute.—At the meeting at Edinburgh, last week, several Papers were read in which the effect of the introduction of the electric light on gas undertakings was discussed. Mr. W. Newbigging, of Manchester, claimed that in no single instance had the introduction of the electric light been detrimental to gas companies. Mr. F. H. Medhurst dealt with the question of the bye-uses of electricity, and Mr. Frank Wright gave, as an instance of the economy of the electric light, the case of the Army and Navy Stores, the managers of which had substituted the electric light for 8,000 incandescent gaslights. He found from practical experience that gas at 2s. 6d. per 1,000ft., used in a flat-flamed burner, was 25 per cent. dearer than electricity at 4d. per unit.

Guildford.—The Board of Trade have written to the Town Council asking for their observations upon a letter the Board have received from the Guildford Electric Supply Company, the undertakers under the Guildford Electric Lighting Order (1894). The letter stated that, although the Company was not in a position at present to prove compliance with the provisions of section 7 of the Order, progress was being made, and the Board of Trade were asked to grant an extension of six months to carry out the provisions of the section. After a short discussion the clerk was instructed to reply to the effect that the Council had no observations to make on the subject.

Hackney (London, N.E.).—At the last meeting of the Vestry the Electric Light Committee were empowered to obtain, at a cost not exceeding £200, the opinion of an expert and collect other evidence and particulars in relation to a combined electric lighting and dust disposal scheme for this parish. It was suggested that the local authorities of Stoke Newington and South Hornsey should be invited to arrange for the electric lighting of that portion of the High-street which lies in their respective parishes.

Hanley.—A special meeting of the Town Council was held on Tuesday last, at which a deputation from the North Staffordshire Tramways Company attended to lay before the Council the Company's views as to electric traction in the district. It was pointed out that the Company had under consideration the adoption of the overhead system of electric tramways, and the consent of the local authority was desired, as if reasonable conditions could be obtained

Digitized by Google

the necessarily considerable amount of capital required would be available. The Company's scheme would involve the entire re-equipment of the line. The Directors, having duly considered the advantages of electric traction, were preparing a comprehensive scheme for extensions from Trent Vale to Longton-road, Stoke, Newcastle to Hanley, Longport to Burslem, Golden Hill and Tunstall to Burslem, and Silverthorne to Burslem. These lines would act as feeders to the main line, and enable the whole system to be worked at a more moderate rate than if the main line only were worked electrically. After full discussion in Committee the Council adopted a resolution approving of the general views of the scheme. The recent application of the Council for powers to borrow £5,000 for electric lighting purposes has received the assent of the Local Government Board.

Lord Kelvin.—The *Pall Mall Magazine* for July contains a handsomely illustrated Paper by Mr. Arthur Warren descriptive of the career of Lord Kelvin, portraits of whom and of Lady Kelvin accompany the text. The illustrations include a view of "Netherhall," Lord Kelvin's country seat, of the testing rooms at White's in Cambridge-street, Glasgow, and of Lord Kelvin's lecture room at Glasgow University. The magazine is beautifully printed and illustrated throughout.

Lambeth (London, S.W.).—The Vestry have again considered the offer of the County of London Company to take over conditionally the Vestry's Provisional Order; and it was finally agreed to refer the matter to the Electric Lighting Committee, two members from each of the standing committees being appointed to act with the Electric Lighting Committee in this matter.

Leeds.—The Yorkshire House-to-House Company have notified their customers of a further reduction in the charge for electric current as from July 1st. The maximum gross charge will be 6d. per unit, while consumers of 1,500 units per quarter will be charged 5¾d. per unit, and consumers of 3,000 units 5½d. per unit. A liberal scale of discounts is also announced, under which the minimum net price is under 4½d. per unit, whilst the greater price payable by any consumer is just under 5¾d. per unit. For heating, cooking and motive power the Company are supplying current at 3d. per unit. The use of electricity for these purposes is steadily extending in Leeds. The number of equivalent 8 c.p. lamps now connected to the mains is about 28,000, compared with 11,500 twelve months ago.

Longton (Staffs.).—At the meeting of the General Purposes Committee of the Town Council last week the Town Clerk reported that a communication had been received from the Board of Trade with reference to the application of the Corporation for sanction to use mechanical power for traction purposes (which had hitherto been refused) on portions of the tramway constructed in the borough in 1881. The Board of Trade now stated that, having regard to the street improvements which had been made and were in contemplation, and to the desirability of extending the tramway system beyond the disused lines, favourable consideration would be given to an application for a Provisional Order authorising such lines afresh and sanctioning the use of steam or other mechanical power thereon. A motion to apply for a Provisional Order was adopted. A letter was read from the Secretary of the North Staffordshire Tramway Company (Limited), stating that the Company had had under consideration the subject of adopting some improved form of traction, and had come to the conclusion that the only method suitable for the district was that of the overhead electric system, and asking for the consent of the Council to the general principle. A deputation was appointed to discuss the matter with the Directors of the Company and report to the Committee.

Middlesboro'.—At last week's meeting of the Town Council, on the proposal to adopt the minutes of the Electric Lighting Committee, a resolution declaring "that it was the opinion of the Sub-Committee specially appointed that it would be in the true interests of the borough to proceed forthwith with the electric lighting scheme at a cost of not less than £25,000" was discussed. This resolution was the outcome of a decision arrived at by the Council about 12 months ago that the Committee should visit several of the principal electric lighting stations throughout the country with the object of obtaining information from various sources. The Committee came to the conclusion that the electric light would be profitable, that it was everywhere preferred to gas, and that it would be advisable that the town's installation should be immediately put in hand. Mr. Alderman Bell, however, advised that the matter should be discussed and dealt with less ambitiously; he approved of the electric light, but thought it would better to commence at a cost of from £10,000 to £15,000, and he moved a resolution to this effect, which, after some discussion, was carried.

Monifieth (Forfar).—The Town Commissioners are considering the question of the lighting of this district. Three schemes, viz.: (1) that of providing an electric lighting installation; (2) the erection of gasworks within the burgh; (3) the obtaining of a gas supply from Broughty Ferry, have been submitted, and a public meeting is to be called for the purpose of obtaining the views of the inhabitants on the question.

Ootacamund (India).—The scheme promoted by the Oriental Electric Light Company, of Bangalore, for lighting Ootacamund by electricity has (says the *Pioneer*) met with great success. The whole of the Government House, including the Military Secretary's and Private Secretary's bungalows, are to be lighted by incandescent lamps, as well as the Government House and Banqueting Hall, the Guindy Park at Madras, and the Government House at Ooty.

Rhyl.—The District Council have informed Messrs. Dickinson and Co., of Birmingham, engineers for the proposed electric tramway at Rhyl, that they will give them every assistance. An interview is to be arranged with the firm, who have invited the Council to send a deputation to the Midlands to inspect the various systems at work there.

Smoke Nuisance.—At the Westminster (London, S.W.) Police Court on Wednesday, Mr. W. R. Renshaw, of the Queen Anne's Mansions Lighting and Heating Works, St. James's Park, was summoned by the Westminster Vestry for permitting the issue of dense black smoke from a chimney so as to cause a nuisance. Defendant pleaded in extenuation that the smoke from this large chimney was no more than the aggregate from smaller chimneys of houses accommodating fewer families than Queen Anne's Mansions. The magistrate (Mr. De Rutzen) said that this amounted practically to a claim that the Queen Anne's Mansions were entitled to a volume of smoke proportionate to the number of tenants, but as these mansions constituted the biggest block of residential buildings in London the result would be the poisoning of the surrounding locality, and therefore the argument would not stand. A fine of £5 was imposed, with five guineas costs.

South America.—Telephone communication has been re-established between Rio de Janeiro and Nictheroy.

Southampton.—The Harbour Board on Tuesday last decided to erect three additional electric cranes, and to erect a supply station on their own property in place of taking current from the local company. Mr. J. G. W. Aldridge, of 9, Victoria-street, Westminster, London, S.W., consulting electrical engineer to the Board, has been instructed to prepare the necessary plans and specifications.

Southport.—In reference to a Note which appeared in our last issue, we find our report was inaccurate as to the reduction in the price of gas. No reduction has been made in consequence of the introduction of the electric light. The Town Council has now approved the adoption of the Brighton method of charging for electric current.

The Southwark Bridge Explosions.—Before Judge Emden, at Lambeth (London), on Tuesday last, a case of considerable importance to the public was tried, arising out of the explosions that occurred in February last on Southwark Bridge. The plaintiff, James Price, was crossing the bridge about noon on the day mentioned when four explosions took place at different points, the pavement being blown into the air, several persons sustaining injuries. This was a test case, and the claims of other persons depended upon its result. Major Cardew, R.E., who held an inquiry into the matter, was called, and said he attributed the explosions to an accumulation of gas in the electric mains. This was, however, controverted on behalf of the gas company, who attributed the fracture to the excessive frost. The Judge considered that negligence had been established—first in that the defendants has not discovered the fracture by the smell of the escaped gas, and also in their not seeing that the pipes were left properly supported after other persons to their knowledge had been excavating and working around them. Judgment was given for the plaintiff, with £12 damages, and costs on the higher scale, but with leave to appeal.

St. Pancras.—The Vestry have postponed the election of a chief electrical engineer for a fortnight. The final selection is to be made from Messrs. S. W. Baynes (Bradford), H. R. J. Burstall (London), and B. Deakin (London).

Swansea.—The report of the Electric Lighting Committee which is to be shortly presented to the Corporation will contain a recommendation that from £50,000 to £60,000 be borrowed to carry out electric lighting and refuse destruction schemes.

Synagogue Lighting.—The new synagogue at Cardiff, which is built to the plans of Messrs. Joseph and Corbett, is to be lighted throughout by electricity.

The "Strike" at Ponders End.—In reply to a question from Sir Charles Dilke, in reference to the strike of a number of the workmen of the Edison and Swan Company at Ponder's End, Sir U. K. Shuttleworth, in the House of Commons last week, stated that the Company were supplying incandescent lamps under an Admiralty contract. He had no knowledge as to the cause of the strike, except such as he had obtained through the newspapers and the Electrical Trades' Union, the officials of which complained that the wages paid by the Company were contrary to the resolution of the

Digitized by Google

House of Commons. It was, however, necessary that the Company should be heard in the matter, and the Admiralty had asked for an explanation. It is almost too much to call this a strike. It is merely a passing incident, the seriousness of which has been much exaggerated.

The Telegraph in Central Africa.—The steamer "Isle of Dursey" has left Glasgow Harbour with 250 miles of telegraph material on board, weighing over 400 tons, for use in the extension of the African Trans-Continental Company's line from Blantyre. Southward from Blantyre the line has been practically completed, with the exception of a short stretch through Portuguese territory which intervenes in the district of the Zambesi. This portion will shortly be completed, when telegrams will be transmissible from Britain to Blantyre without interruption. The projected extension to the north, for which the material is taken by the "Isle of Dursey," will proceed from Blantyre by Lake Nyassa to Karonga, and thence to Abercorn, at the southern extremity of Lake Tanganyika, from which the line will pass along the western side of the waterway. The African Lakes Corporation of Glasgow have undertaken to deliver it at Chikwawa, on the Upper Shire, in British Central Africa. The telegraph posts are lightly made of steel, wooden poles being quickly destroyed by the white ants which infest the district.

Telephonic Communication for Fire Brigade Stations.—At the last meeting of the County Council, on the recommendation of the Fire Brigade Committee, it was agreed to connect the Bishopsgate fire-engine station and the fire-escape and horse-cart stations in Eastcheap and Finsbury by telephone.

Tiverton.—Last week the Mayor presided over a meeting convened for the purpose of considering the question of establishing a telephone service in the town. The Chairman said the National Company were prepared to put Tiverton in communication with the outer world if the town could guarantee 20 subscribers at an annual rent of £8 for five years. After a short discussion a committee was formed to make further inquiry and report to a future meeting.

Tramways Institute.—The annual general meeting of the Tramways Institute of Great Britain and Ireland will be held at the Holborn Restaurant, London, W.C., on Thursday next, the 27th inst., at 11 a.m. Included in the business is the reading of the following Papers:—"Traction and Lighting by the International Electric Storage Accumulators," by Mr. A. G. New; "Thwaites and Cawley's System of Electric Haulage," by Mr. G. Cawley, &c.

Warehouse Lighting.—The Midland Railway Company's extensive range of warehouses at Liverpool, now in course of erection, and which are estimated to cost, with the site, a quarter of a million sterling, are to be illuminated by the electric light, the plant consisting of three Davey Paxman two-cylinder engines, each driving a Thomson-Houston dynamo, and two smaller engines driving Edison-Hopkinson machines. A hydraulic plant is also to be installed, and this, with the electric lighting plant, is in charge of Mr. S. L. Smart, the Company's resident engineer. Mr. Chas. Trubshaw, the Company's architect, has prepared the plans and designs, the contractors being Messrs. W. Brown and Son, of Salford, who have, it is stated, executed work for the Midland Company in different parts of the country to the amount of about five millions sterling.

West Ham.—At the last meeting of the Town Council the recommendation of the Highways and Parks Committee that 12 leading electrical firms be invited to submit estimates for an installation of the electric light for the compulsory area, and that the Committee be empowered to draw up the conditions of tendering and report to the Council thereon, was adopted.

Works Lighting.—Considerable improvements have recently been made in the new plate mill at the Butterley Company's Ironworks, Codnor Park, including the addition of the electric light, consisting of seven 2,000 c.p. arcs and some incandescents. A Robey engine forms a portion of the plant.

COMPANIES' MEETINGS AND REPORTS.

Electric and General Investment Company (Limited).

The following report of the Directors of this Company for the year ended May 31st last will be submitted to the sixth ordinary general meeting of shareholders to be held at Winchester House, Old Broad-street, E.C., on Tuesday, July 2nd, at 3 p.m.:—

The profit and loss account shows a gross profit on the transactions of the year of £8,470. 17s. 1d., and after deducting all standing charges and the interim dividend already paid on the Ordinary shares, there remains a net balance available for distribution of £5,330. 13s. The Directors now recommend the payment, out of the profits for the past year, of a further dividend upon the capital paid up on the Ordinary shares at the rate of 30 per cent. per annum for the past six months, and a dividend on the Founders' shares of £20 per share for the year. This will leave a balance of £330. 13s., which the Directors recommend should be added in equal moieties to the reserve funds of the holders of the Ordinary and Founders' shares.

The trustees for the Founders' Shares Reserve Fund propose to distribute to the holders of such shares a sum of £15. 16s. per share out of the proceeds of investments sold and dividends received, making, with the before-mentioned dividend, a total distribution of £35. 16s. on each Founders' share.

The Directors who retire this year are Lord Cloncurry and Mr. Braithwaite. The latter offers himself for re-election, but Lord Cloncurry permanently retires, on account of his continued residence in Ireland. The auditor, Mr. Rait, seeks re-election.

NEW COMPANIES, STATUTORY RETURNS, &c

BEAMAN AND DEAS SYNDICATE (LIMITED).—This Company was registered on June 17th with a capital of £30,000, in £50 shares, to acquire from S. J. Beaman and J. Deas, engineers, of Warrington, Lancs., certain patent rights in connection with "improvements in destructor furnaces," and to carry on the business of contractors, boiler makers, wire drawers, engine builders, and manufacturers of and dealers in electric, magnetic, telephonic, and other apparatus. The first Directors are S. J. Beaman, J. Deas, T. Tunstall, J. L. Tunstall and W. Griffiths.

CORK ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—This Company was registered on June 15th in Dublin, with a capital of £1,000, in £1 shares, to carry on the business of an electric light, heat, and power supply company, to carry out contracts for the lighting by electricity of towns, villages, public and private buildings, &c., and to carry on the business of electricians, mechanical and electrical engineers, suppliers of electricity, and manufacturers of and dealers in motors, generators, converters, meters, lamps, batteries, and all apparatus and materials used in connection with the generation, accumulation, supply, distribution, and utilisation of electricity. The subscribers, with one share each, are: M. D. Daly, J.P.; E. Hall, J. Morrough, J. Dwyer, J.P.; J. Peardon, W. McGrath, H. Dale, J.P.; J. Pike, J. G. McCarthy, W. H. Hill, A. C. Reilly, J. H. Scott, E. J. Julian and R. A. Atkins, all of Cork.

CRAMP MANGANESE BRONZE COMPANY OF GREAT BRITAIN (LTD.).—This Company was registered on June 14th with a capital of £50,000, in 25,000 Preference and 25,000 Deferred shares of £1 each, to carry on the business of manufacturers or workers of and dealers in bronze and other metals or metallic alloys, metallurgists, civil, electrical, marine and mechanical engineers.

ELECTRIC ORGAN COMPANY (LIMITED).—This Company was registered on June 15th with a capital of £110,000, in 55,000 £6 per cent. cumulative £1 Preference shares, and a like number of Ordinary shares of similar value, to carry into effect five agreements made between the Hope-Jones Electric Organ Company (Limited), Robert Hope-Jones and others, to apply electric and pneumatic action to organs and other musical instruments, and to carry on the business of builders and manufacturers of organs and musical instruments, electricians, and manufacturers of and dealers in electrical, pneumatic and other apparatus. The subscribers, with one share each, are: T. Threlfall, Robert Hope-Jones, H. Crewdson Howard, A. W. Speed, A. Foxworthy, R. Hope-Jones and H. R. Terry. The first Directors are: J. E. Austin, A. W. M. Bosville, R. Hope-Jones, T. Threlfall and J. M. White.

INDIA-RUBBER, GUTTA-PERCHA AND TELEGRAPH WORKS COMPANY (LIMITED).—The annual return to February 28th was filed on the 11th ult. The nominal capital is £812,000, in £10 shares, of which 50,000 have been subscribed for and allotted, and upon each of these the full amount has been called and paid.

INDO-EUROPEAN TELEGRAPH COMPANY (LIMITED).—The annual return to May 13th has been filed. The Company's capital is £450,000, in 18,000 £25 shares. Of these 17,000 have been taken up, and the full amount has been called and paid.

INTERNATIONAL ELECTRIC STORAGE (LIMITED).—This Company, which has left its registered office, has failed to file its statutory returns, and its name, we learn, is to be struck off the register of joint stock companies unless it complies with the provisions of the Companies Acts.

KENNEDY STORAGE BATTERY COMPANY (LIMITED)—The annual return to December 31, 1894, has been filed. The whole nominal capital of £100,000, in £1 shares, has been taken up, and issued as fully paid. The Directors have not yet been able to obtain the transfer of the Company's patent, but they desire to retain the registration.

LONDON PLATINO-BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The annual return to May 20th has been filed. The nominal capital is £400,000, in £10 shares. Of these 37,548 have been subscribed for and allotted, and the full amount called and paid thereon.

RAILWAY ELECTRIC READING LAMP COMPANY (LIMITED).—The annual return to May 10th has been filed. Only seven shares have been subscribed for out of a nominal capital of £100,000, in £5 shares, and nothing has been called.

CITY NOTES.

AFRICAN DIRECT TELEGRAPH COMPANY (LIMITED).—The coupons on this Company's Four per Cent. Mortgage Debentures, due on July 1st next, will be paid on and after that day at Parr's Banking Company and the Alliance Bank, Bartholomew-lane, London, E.C. Coupons to be left three clear days for examination. The debenture register will be closed from the 24th to the 29th inst. inclusive.

ACME AND IMMISCH ELECTRIC WORKS (LIMITED).—A private meeting of the members of this Company was held at the works, Ferdinand-street, Chalk Farm-road, London, N.W., on Wednesday last, to which the Press were not admitted.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—The coupons on this Company's second issue of Five per Cent. Debentures, due the 30th inst., are payable on and after the 29th inst. at Parr's Banking Company and the Alliance Bank (Limited), Bartholomew-lane, E.C. Coupons to be left three clear days for examination.

CALLS DUE.—An instalment of £2 per share on the first issue of 10,000 Six per Cent. Cumulative Preference shares of the County of London and Brush Provincial Electric Lighting Company (Limited) becomes due on the 29th inst.

CHELSEA ELECTRICITY SUPPLY COMPANY (LIMITED).—A confirmatory meeting to approve certain modifications in the Articles of Association of this Company was held at Draycott-place, Cadogan-gardens, London, S.W., on Wednesday last.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended June 16th were £862, as against £831 in the corresponding week of 1894, being an increase of £31. The total receipts for the half-year amount to £22,299, against £21,755 for the corresponding period of 1894, an increase of £544.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—The transfer books of the debenture stock of this Company will be closed the 24th to the 30th inst., inclusive, for the preparation of interest warrants.

CROMPTON AND CO. (LIMITED).—In the Chancery Division, on Monday, Mr. Justice Romer sanctioned a petition for the reduction of the capital of this Company by a sum of £20,000, the reduction to be effected by the cancellation of 4,000 Ordinary fully paid up shares, that amount having been lost or being unrepresented by available assets.

GREAT NORTHERN TELEGRAPH COMPANY.—Coupons fallings due on July 1st on the shares of this Company will be paid by Messrs. C. J. Hambro and Co., 70, Old Broad-street, London, E.C. Coupons have to be left three clear days for examination.

W. T. HENLEY'S TELEGRAPH WORKS COMPANY (LIMITED).—This Company have declared an interim dividend of 6s. per share, free of income tax, on the Ordinary shares of this Company, payable on August 1st next.

INDO-EUROPEAN TELEGRAPH COMPANY (LIMITED).—This Company is prepared to receive, at its offices, 18, Old Broad-street, on and after July 1st, applications for the sixth series of coupons, to be issued to holders of share warrants to bearer in this country. Application must be made on printed forms obtainable at the Company's offices.

LIVERPOOL ELECTRIC SUPPLY COMPANY (LIMITED).—An extraordinary general meeting of this Company is to be held on the 22nd inst. for the purpose of approving the following resolutions:—"1. That an agreement, dated May 28, 1895, entered into between the Company and the Mayor, Aldermen and citizens of the City of Liverpool, for the sale of the undertaking of the Company to the Corporation, be approved, subject to such alterations as Parliament may see fit to make therein. 2. That the Company apply to Parliament in the present session for an Act to make all necessary and useful provisions for effectuating such sale, for the distribution of the price thereof and the assets of the Company, and for the eventual winding-up and dissolution of the Company, and that the Directors be instructed to take all necessary steps for obtaining such Act. 3. To determine the provision to be made in such Act or otherwise for the appropriation and distribution of the reserve and renewal fund of the Company and the payments to be made to the Directors and any officers and servants of the Company in recognition of their services. 4. That the Bill for the Act now submitted to the meeting be approved subject to such additions, alterations and variations as Parliament may think fit to make therein." If these resolutions are legally approved, a confirmatory meeting will be promptly called.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 16th inst. amounted to £1,268. The amount for the corresponding week last year was £882; increase, £386.

MANCHESTER SUBURBAN ELECTRIC SUPPLY (LIMITED).—It is stated that arrangements are now completed in connection with the above Company. The share capital is to be £25,000, in 3,000 Six per Cent. shares and 22,000 Ordinary of £1 each, half of which are offered for subscription. The registered offices are 8, South King-street, Manchester, and Mr. J. K. Lawton is secretary *pro tem.*

PACIFIC AND EUROPEAN TELEGRAPH COMPANY (LIMITED).—The coupons on this Company's Four per Cent. Guarantee Debentures, due the 30th inst., are payable on and after the 29th inst. at Parr's Banking Company and the Alliance Bank (Limited), Bartholomew-lane, E.C. Coupons to be left three clear days for examination.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended June 14th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,389.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the half-month ended June 15th are £2,085, as compared with £2,181 in the corresponding period of 1894. The February receipts, estimated at £4,746, realised £4,808.

WOODHOUSE AND RAWSON UNITED (LIMITED).—The Five and a-Half per Cent. Debenture-holders in this concern met by adjournment, before Mr. C. J. Stewart (Official Receiver and liquidator), at the Carey-street offices of the Board of Trade, to consider the proposal to proceed against the Directors and other officials with a view to recovering certain moneys for which they are thought to be liable. Mr. Stewart said that although the whole of the Ten per Cent. Debenture-holders and a majority of the Six per Cent. Debenture-holders had on the last occasion voted against the institution of proceedings, it had to be borne in mind that substantial dividends would, no doubt, be paid to those two classes of creditors, who consequently disliked the idea of entering into litigation and risking the assets which were to be available for the costs. The present meeting would probably take a different view, as there was no prospect of any dividend whatever being paid to them. The business of the meeting was to consider whether proceedings should be taken against the Directors and other officials of the Company with a view to the recovery of moneys, and whether an arrangement could be made with the other classes of the debenture-holders under which some benefit would accrue to the holders of the Five and a-Half per Cent. Debentures. A resolution in favour of the proposed proceedings was negatived by a substantial majority.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 893. [No. 9. Vol. xxxv.] FRIDAY, JUNE 28, 1895. PRICE SIXPENCE.

NOTES.

THE year 1895 seems destined to be written in letters of fire in the annals of electric lighting in London. Early in February, as our readers will remember, there was a serious fire at the Kensington Court station of the Kensington and Knightsbridge Electric Lighting Company, and on Monday evening last the Metropolitan Electric Supply Company's station in Sardinia-street was practically destroyed by fire. The flames burst out with great suddenness in the upper floors about a quarter past 6 o'clock in the evening and the fire spread with the utmost rapidity, notwithstanding the streams of water from the hydrants fitted to the premises. The interruption of the supply of the district served by the station was, however, only of short duration, thanks to the energy and good will of the staff. By 8:30 most of the theatres and other important buildings in the neighbourhood of the Strand were lighted as usual from the Metropolitan Company's remaining stations and by to-day it is anticipated that current will be available to everyone as usual. No lives were lost and no secondary accident, beyond the bursting of a steam-pipe, was caused by the conflagration. The catastrophe could scarcely have happened at a more awkward time, and the Company must be congratulated on so quickly getting a supply to its more important customers. It is to be hoped that these two disasters will bear fruit in more elaborate structural and mechanical precautions against fire. The cause of the fire is still unknown.

AFTER nearly four years of incubation the Central London Railway scheme has been brought to the notice of the investing public, who would appear to have formed a higher opinion of the prospects of this line than they did of those of the Great Northern and City Railway in February last. A contract has been entered into with the Electric Traction Company (Limited) for the acquisition of land and the construction and equipment of the railway for the sum of £3,244,000, of which £2,544,000 is to be in cash and £700,000 in Four per Cent. Debenture Stock. The line is to be opened for traffic by December 31, 1898.

WITH the experience which has been gained from the construction and working of the City and South London Railway, the Central London Railway should present no unsolved problems either to the civil, the mechanical, or the electrical engineer, and in view of the much larger traffic and smoother load-curve, the line should also prove a more decided financial success than the pioneer concern. Indeed, the only unknown quantity in this undertaking is the Electric Traction Company (Limited), which at present consists of the usual seven signatories, none of whom are known to fame. It is to be hoped that the intervention of this concern does not portend anything in the shape of financial finesse. The construction and equipment of the line is, it would appear, to cost something like £500,000 a mile; the figure for the City and South London Railway is less than £300,000. It is not very obvious why there should be this enormous difference. An increase of 15 per cent. in the diameter of the tubes cannot surely be responsible for an increase of some 75 per cent. in the cost of construction and equipment.

A SOMEWHAT sensational statement was put forward a few days ago by a daily contemporary to the effect that when all the five Post Office telephone circuits between Leeds and London are in simultaneous operation the induction is so serious that the remedial measures which will have to be taken will greatly delay the opening of the lines to the public. It is quite true, we believe, that there is some cross-talk when all the circuits are being used, but it can scarcely be characterised as serious, and the proposed remedy, as we stated in our issue of June 14th, is merely to cross the mutually interfering circuits at long intervals, crossing having so far proved quite effectual.

EVEN if it possessed no practical advantages over the mechanical analyser, or were distinctly inferior to it as an engineering instrument, the graphical method of developing periodic complex functions in a Fourier's series, which is discussed by Prof. PERRY in an article this week, would at any rate have the advantage of being of higher educational value. Prof. PERRY, if we understand him rightly, thinks that this graphical method of CLIFFORD's might actually be ranked among practical engineering instruments and processes. It would, at any rate, speak well of the mathematical tastes and abilities of the profession were it to become so; and we are quite ready to admit that the modern engineer is far more scientific than the engineer of yesterday. But, with the glorious intricacies of Prof. PERRY's diagram befor us, we hesitate to believe that this elaboration of curves is likely to find any very general use in the engineer's office.

Digitized by Google

We do not overlook the fact that, in a time competition with a harmonic analyser, the graphical method came in a very good second; but this achievement presupposes an expert at work on either side, and the average man is, we venture to think, more likely to become expert with an analyser than with Fourier's series and all its works. Educationally, however, Prof. PERRY's graphical treatment of an idea originally due to Prof. CLIFFORD is exceedingly valuable; though even grinding away at a mechanical analyser is an employment not altogether without educational value to some minds.

THE notes which we print elsewhere on some experiments upon the attraction between a solenoid and a cone-shaped iron core are of interest as indicating one way of producing a mechanical movement of some considerable power that shall have a motion proportional, over a limited range, to the current passing through the apparatus. Doubtless there is scope, in many mechanical applications, for electromagnetic mechanism of this order. Not much has been done in this line since the researches of BRUGER, which, however, were directed to a different end. We would throw out the suggestion to those interested in mechanisms of this kind that something might be done toward the attainment of a closer proportionality by the application of a graphic construction to connect the shape of the core with the width of gap in the magnetic circuit and the saturation of the core, so as to make the travel for a given controlling force (such as gravity) proportional to the ampere-turns of exciting current. Mr. McMAHON's experiments seem to show that no part of the travelling core ought to be cylindrical.

IN our "Correspondence" columns this week will be found a long letter from Messrs. HOUSTON and KENNELLY anent some editorial criticisms with regard to the nomenclature and symbols adopted by them in their valuable "Contribution to the Theory of Demagnetisation," which appeared in our issue of May 31st. As to "block" letters *versus* "black" letters for magnetic quantities, we can only repeat what we have said before—namely, that the table of symbols referred to by Messrs. HOUSTON and KENNELLY was practically the work of a single individual, and was merely *recommended* by the Congress. To possess any international validity and force such a sweeping reform should be the outcome of the careful consideration of experts, and not the work of a single hand blessed by the hurried recommendation of an overworked Congress. Until some such properly considered, properly authorised edict is promulgated, everyone who adopts any of the variegated symbols contained in the recommended table does so because he individually prefers them, not because he must do so under pain of being classed as a scientific free lance.

As regards our correspondents' remarks about the use of the word "gauss," we still hold the view that the "misconception" is with those who regard magnetising force (**H**), and magnetic flux (**B**) as "essentially the same physical quantity." It is, of course, true that in what is known as the electromagnetic system of units the dimensions of **B** and **H** are identical. But this is only because the dimensions of μ, the permeability, are ignored, just as, in the corresponding electrostatic system, the dimensions of K, the specific inductive capacity, are omitted. It is quite arbitrary to neglect the dimensions of μ and K, and look upon them as mere numbers. In the electromagnetic theory **B** and **H** have to be regarded as distinct physical quantities with different dimensions, for it is impossible any longer to neglect the physical nature of μ and K. Our correspondents' remarks about the measurement of these quantities only show that magnetic flux (**B**) can be measured, for they estimate **H** from the flux of induction it produces. This process is quite legitimate, but the quantity primarily measured is **B** and not **H**. If our only way of measuring voltage was by the current it produced in conductors, we should use such a method, as indeed we do in most cases; but that would not alter the fact than an electromagnetic voltmeter acts primarily from current, not from volts; nor would it make it legitimate to regard a volt and an ampere as the same kind of quantity.

Cable Interruptions.—There are no cable interruptions to report this week.

City and South London Railway.—As a train on the City and South Lond on Electric Railway from Stockwell was entering the Oval station shortly before 10 o'clock on Saturday morning last, the last coach left the metals and caught fire. The line was blocked for some time. No one was injured.

Argon.—At a recent meeting of the Académie des Sciences M. Berthelot announced that he had succeeded in making argon combine with bisulphide of carbon under the action of the electric discharge. M. Berthelot subsequently recovered the argon that had combined with the bisulphide of carbon.

Electric Lighting of the Side Streets of the City.—At the last meeting of the City Commissioners of Sewers the suggestions of the electrical inspector, Mr. Voysey, referred to in our issue of June 14th, were adopted, and the Streets Committee were requested to consider the desirability of experimenting also with incandescent gas lamps.

Strand Electric Lighting Order.—On Wednesday last Lord Camperdown's Committee on the Strand Electric Lighting Order heard further evidence as to the relative merits of the methods employed by the Charing Cross and the Metropolitan Companies, the latter being supported by Lord Kelvin and Mr. Ferranti. The Committee passed the Order.

A Water Power Bridge.—According to an American technical journal a plan is on foot in Buffalo to erect a bridge across the Niagara River, and beneath it to place a number of undershot water wheels, which would be used to drive dynamos which would furnish light and power to the city. It may be remembered that Old London Bridge had water wheels arranged in this manner.

Personal.—The staff of the Indo-European Telegraph Company have presented Mr. W. Andrews, the Managing Director of the Company, with a handsome silver casket, in celebration of his completion of 25 years' control of the management. In making this announcement, *The Times* compliments Mr. Andrews and the Indo-European Company on the distinguished services rendered by them to Indian communications, and especially upon the accuracy and punctuality with which the leading journal's Indian correspondence over the Company's system has been accomplished.

Road Traction.—On page 249 of our last issue we alluded to a Bill, which Mr. Shaw Lefevre had brought in, to amend the law with respect to the use of locomotives on highways. As we then stated, the Bill contains only one clause, and its object is to facilitate electric and similar road traction by exempting carriages so propelled from the regulations of the

Digitized by Google

Locomotives Act. A copy of this Bill has now been published, and it may be interesting to state that the weight of the vehicles which are to be exempted from the application of the Locomotives Acts of 1861 and 1878 must be less than two tons.

Accident on the Chicago Elevated Railway.—"It is to be regretted," says the *Western Electrician* of Chicago, "that a fatal accident, due to the electric current, has already occurred on the electrically operated metropolitan elevated road in Chicago. On Monday, June 10th, a workman employed on the structure started to climb to the top. In doing so he grasped one of the conducting rails, and as his body was in contact with the metal structure he received the heavy operating current through his body at the pressure of 500 volts. He was unable to release himself, but fellow workmen finally pulled him away and removed him to a place of safety, where he died in ten minutes."

Aluminium-Copper Telegraph Wires.—Tests have recently been made of some aluminium-copper wires intended for use in connection with the Monteil Trans-African Expedition. The percentage of the alloy composing these wires is 40 per cent. aluminium and 60 per cent. copper. The resistance of a kilometre of these wires having 1mm. cross-section is found to be 31·1 ohms for soft and 33·29 ohms for hard-drawn wire, the resistance of an ordinary copper wire of the same dimensions being 16·45 ohms. The tensile strength of wires of this alloy, 2·3mm. in diameter, was found to be, on an average, 28 kilogrammes per square millimetre (17·78 tons per square inch).

Electric Lighting at Berlin.—In the annual report of the Berlin Town Council on the administration of the municipal gasworks some interesting figures are given in regard to electric lighting in Berlin. There are in all 185 street arc lamps, 71 of which are alight all night, the remainder only burning up to midnight. For private purposes there are 9,932 arc lamps, 200,474 glow lamps, and 667 motors and apparatus. Of these, 4,259 arc and 79,212 glow lamps are supplied by isolated plants, of which 251 are driven by steam and 97 by gas engines. Current for the remainder is supplied by the Berlin Electricity Works. The increase of the lamp connections over those connected at the end of the previous year (1893) was 16·23 per cent.

Royal Society Government Grant.—Of the sum of £4,000 annually voted by Parliament to the Royal Society, an appropriation has been made which includes several grants for electrical and allied researches. Among these we notice the following:—£25 to Messrs. J. Holm and J. R. Erskine-Murray, for experimental investigations on contact electricity of conductors; £50 to Prof. G. M. Minchin, for the measurement of the electromotive forces developed in certain photo-electric cells by the light of the moon, planets and stars; £150 to Prof. O. J. Lodge, for assistance in experiments intended to elucidate the connection between ether and ordinary matter; £162. 10s. to Mr. R. Threlfall, for preparation of pure selenium and exact determination of its electrical properties.

Electro-magnets and Hot-Wire Devices.—Referring to a recent discussion on the relative advantages of electro-magnets and hot-wire devices which took place in the columns of the *Electrical Engineer* of New York, Mr. W. M. Stine observes that "it should be borne in mind that a heated wire acts in a sense like a spring which may be expanded and contracted by the heating power of an electrical current. On the other hand, an electro-magnet acts in many cases as an ether stress spring, and, being practically massless, must always be greatly superior to a material spring. The faults of the electro-magnet are hysteresis, residual magnetism, &c.; of the hot wire, sluggishness, drift, variation of constants, &c. The hot wire acts by virtue of the C^2R loss in it, and primarily absorbs power; the electro-magnet acts in proportion to its ampere-turns, and only incidentally absorbs power. Though the hot wire is in general an inferior device when compared with an electro-magnet, there are cases in which it can be used to advantage."

Damage by Lightning.—At Crewe, on Wednesday afternoon, lightning struck a chimney in the railway works, and the chimney fell. Chimney-stacks in Alton and Lockett-streets were also smashed. Considerable damage was done in the district.—At Normanton two miners returning from their employment were killed by a flash of lightning.—At Hammersknott Park, the site of the Royal Agricultural Society's Show, five people seeking shelter under an ash tree situated a short distance from the members' pavilion, were struck by lightning, and two were killed.—During a heavy thunderstorm which passed over Wisbech and district on Wednesday, last week, one of the lighthouses at Sutton Bridge was struck by lightning and almost completely wrecked. There is a hole nearly 6ft. wide in the top of the lighthouse, and the walls of the building are cracked in all directions.—An American barque, loaded with petroleum, and on a voyage from Philadelphia for Havana, when off the Bahamas, on the night of May 21st, was struck by lightning. One of the oil tanks exploded and set fire to the ship. The captain and some of the crew perished; only six survived.

The Efficiency of Heaters.—The German Hygienic Association, says the *Gas World*, offers a prize of £225 for a research essay on the heat given out by heaters. The programme is "The heat given out in heating installations by heaters in their various forms and modes of use is to be ascertained. The investigations are to be described in detail in respect to the arrangement of the heaters, the nature of the heating agents, and the observations made; and they are to be illustrated by drawings. The heating values obtained are to be stated in units of heat given off per hour per unit of surface. In the case of heat given out to air, the investigations must be conducted with currents of air at speeds as different as possible. The heaters are to be described in detail as regards form and measurement, and the relation of their heating efficiency to their weight is also be ascertained." Essays to be written in German, with a motto and sealed envelope, and sent to Prof. Konrad Hartmann, Charlottenburg, Fasanenstrasse 18, before July 1, 1896. The essay will remain the property of the successful competitor, but he must publish it within six months, and give the prize offerers 300 copies gratuitously. The prize may be divided or withheld.

The Brighton-Rottingdean Seashore Electric Railway.—At the last meeting of the Brighton Town Council a letter, dated May 24th, from Mr. Magnus Volk was brought before the notice of the Council by a Committee. The letter stated that the Brighton and Rottingdean Seashore Electric Tramroad Company found that the power required to drive the car through the water could only be ascertained by actual experiment, and were advised that the best means of ascertaining this would be to drive the car in the first instance by means of a small surface-condensing steam engine of the marine type, which the Company undertook would neither emit steam nor smoke. The contractors were prepared to give an undertaking to remove the steam engine within six months at the very outside, and would be quite willing that permission should be given only on condition that neither smoke nor steam were emitted. The Borough Engineer and Surveyor handed in a lengthy report on the subject, stating amongst other things that to his mind it was very questionable whether the use of steam engines, even temporarily, was authorised by the Company's Act of Parliament. After a lengthy debate the Brighton Town Council decided by 28 votes to 3 to confirm the Committee's recommendation and to refuse the permission asked for.

An Electric Lighting Act for India.—In a recent issue the *Times of India* gives a *précis* of the statement of objects and reasons appended to the Bill to facilitate and regulate the supply of electricity for lighting and other purposes in Calcutta. The Government has at present no power to grant a licence or provisional order for the supply of electricity. The Indian Telegraph Act, 1885, under which licences have been granted to telephone companies, deals only with appliances for making communications by means of electricity. Act No. XIII. of 1887 is an Act to provide for the protection of person and property from the risks incident to the supply and use of electricity; but it does not provide for the grant of licences. Nor does it provide for many other matters which are essential for the protection of contractors from undue interference or restraint, and the public from excessive charges and undue

Digitized by Google

preference. These matters cannot be satisfactorily arranged without legislation. The object of the present Bill is to enable the Government of Bengal to grant licences for the supply of electric lighting within any part of Calcutta. The Bill closely follows the Electric Act of 1882 (44 and 45 Vic., Cap. 56); but as it is intended to empower the Local Government to grant licences only, every reference to "provisional orders" and "special Acts" has been omitted. The Local Government is substituted for the Board of Trade throughout. The definition of Calcutta is taken from the Calcutta Municipal Act of 1884; but power is given in the Bill for extending its provisions to the Howrah Municipality. The necessary powers for breaking up streets, &c., for the purpose of supplying electricity within the area specified in the licence have been adopted for the most part from the Gas Works Clauses Act of 1871.

Kew Observatory.—An account of the past year's work of the Kew Committee of the Royal Society is given in a recent number of the *Proceedings* of the Royal Society. The grounds of the observatory have been augmented by about five acres; and, at the expense of the Chairman, Mr. F. Galton, a substantial paling has been erected round the premises in the Old Deer Park, Richmond. The ordinary departments of the observatory have been carried on in the usual manner, and with little or no interruption. Advantage was taken of the great frost in January to dismount and overhaul the electrograph; and this same instrument had, in August, an enforced holiday of nearly three weeks, owing to the accidental breakage of a suspension thread. Prior to starting on the Jackson-Harmsworth North Polar Expedition, Mr. Armitage received at the observatory a short course of instruction in the use of magnetic instruments, and some instruments from Kew were taken upon that expedition. In the department of thermometer testing, arrangement is, as announced at the last meeting of the Physical Society, about to be made for platinum thermometers to be tested and calibrated. There is a considerable increase in the number of instruments tested, the total being 20,936, as against 20,197 for the previous year. Of this total, however, no less than 15,593 were clinical thermometers; while the number of standard thermometers tested was 74, as against 88 for the previous year. In each case the calendar year is referred to. A useful department of work is the transmission of reliable photographic paper to various physical and other observatories throughout the world. It is interesting to notice that an institution of the scientific character of the Kew Observatory is self-supporting, by virtue of the revenue arising from fees for tests, &c., to the extent of £1,943, out of a total revenue of £4,173.

Thomson Carbon Brush for Low Potential Machines.—While carbon brushes have proved eminently successful for high potential machines, says the *Electrical Engineer* of New York in a recent issue, they have not been shown to be so satisfactory for the ordinary low potentials of 110 volts and under. This, of course, is largely due to the heat generated in the carbons by the heavy currents and the additional pressure required to get a good contact. One of the methods of overcoming this difficulty, employed in the past, has been to mix with the carbon a more or less conducting material. Recently, however, Prof. Elihu Thomson has devised another method. Instead of employing a solid block, use is made of a number of small rods of carbon plated with a thin film of copper. These rods are assembled in the form required and of the required size so as to give the desired thickness, length and width of the brush, and the copper plated carbon pieces are united by soldering, that is, by "sweating in" solder between them in a sufficient number of places to hold them together. The carbon surface applied to the commutator is broken away into facets, and the current which is taken from the commutator through the carbon faces is at once delivered to the metal which unites the various carbon pieces and is conducted through the body of the brush by the metal chiefly. The metal is so thin that the moment it touches the commutator at any point, the extra conductivity causes it to shunt enough current to disintegrate it at once, so that at all times the carbon surfaces take the wear and the metal is eaten away a short distance as rapidly as the carbon is presented. This method of construction also permits of the conductivity of the brush being varied to suit the current to be taken up, and the potential of the dynamo will determine the amount of the metal which is to be used relatively to the carbon; that is, by plating the pieces more heavily the conductivity can be raised between limits, and by putting the merest film of metal on the carbon pieces it can be lowered.

Obituary.—We regret to record the death, on the 23rd inst., at Copenhagen, of Col. O. V. Hoskiaer, who was born in that city on June 25, 1829. After having passed the Danish Military High School and the lower military grades, he served in the Dano-German War in 1864, at the defence of the fortress of Fredericia. After the war he served as a captain—afterwards colonel—of the Royal Engineers, and was, in 1867, appointed chief of the Telegraph Corps, remaining in the army until 1890, when he retired. For several years Col. Hoskiaer was *aide-de-camp* to the King of Denmark, and on different occasions he acted in a similar position to various royal visitors at the Danish Court. With his extensive technical knowledge, his energy, and his linguistic attainments, he naturally took an active and leading part in several industrial undertakings in his country, and was a prominent member of several technical and learned associations, among these being the Technical Society of Copenhagen, of which he was President. With the Great Northern Telegraph Company he was connected almost from its formation. During the manufacture and laying of the Company's cables in China and Japan he was their controlling engineer, and acted in a similar capacity on several subsequent occasions, afterwards joining the Board of Directors of the Company. His kindness, affability, and never-failing courtesy won for him many friends, not only in his own country, but also abroad, and especially here in England, where he was a frequent visitor. Col. Hoskiaer is the author of several works in Danish, and in this country his "Guide for the Electric Testing of Telegraph Cables," which has passed through three editions, is well known, and has a wide circulation.

The Spectrum of Carbon from the Electric Furnace.—In a recent communication to the Académie des Sciences, M. Deslandres stated that M. Moissan recently pointed out that the carbons which he uses for his electric furnace are purified by the passage through them of the large currents employed. As it is very difficult to purify carbon by the chemical way, M. Deslandres emphasizes the importance and interest of this property of the electric furnace, especially to spectroscopists who often use pure carbon in qualitative analysis. It was on this account that M. Deslandres paid special attention to the statement of M. Moissan, and carried out an investigation to verify its correctness. M. Moissan placed at M. Deslandres' disposal two carbon electrodes, a positive and a negative, 20cm. long and 5cm. thick, which he had made use of in some electric furnace experiments. M. Deslandres took from each electrode small pieces of carbon at distances of 15, 10, 5 and 1cm. from the arc. He found that the pieces which were taken from the electrode at some distance from the arc showed the ordinary impurities of carbon, namely, alkaline metals, together with copper, iron and silicium. When, however, he came to examine the pieces which had been taken close up to the arc, the bands denoting impurity finally disappeared, with the exception of the calcium bands, which, although very much reduced, always remained visible, a fact which M. Deslandres attributes to the lime wall of the furnace, which is probably partly volatilised when large currents are used. M. Deslandres attributes this purification of carbon to a purely physical cause, the impurities being much more volatile than carbon, and being therefore vapourised before it. The purest carbon was obtained from the mushrooms which form on the negative, and with one of these mushrooms M. Deslandres obtained a spectrum which contains fewer impurity bands than any of the spectra hitherto published. It would be interesting to know whether other substances than carbon could be freed of their more volatile impurities by this process; *e.g.*, whether platinum or gold might be refined in small quantities by this means more readily than by any other.

PERIODIC FUNCTIONS DEVELOPED IN FOURIER SERIES.—THE GRAPHICAL METHOD.

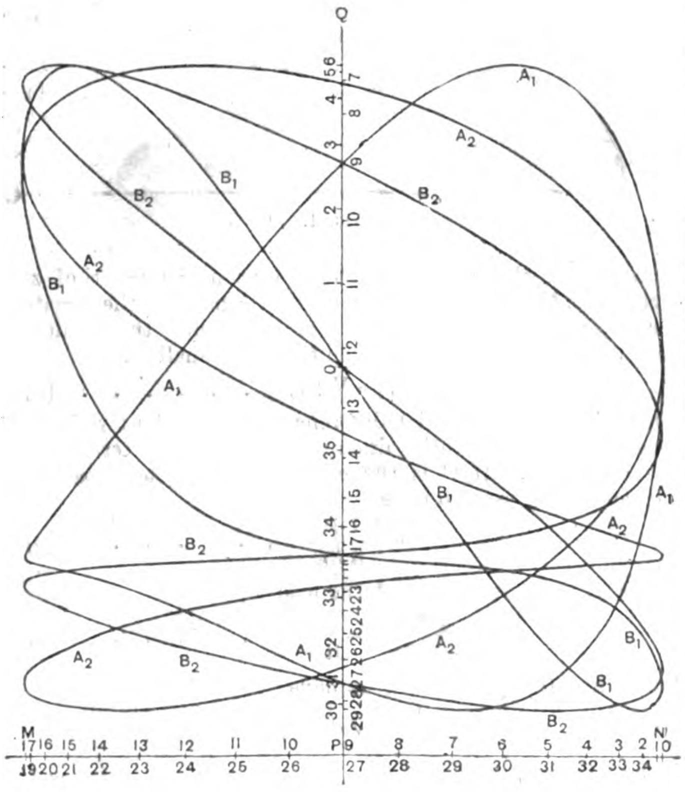
BY PROF. JOHN PERRY, F.R.S.

More than a year ago I described, at a meeting of the Physical Society, how my students at Finsbury were accustomed to utilise Prof. Clifford's idea as to the Fourier development. Since then I have several times been obliged to describe in detail the actual process employed. It is so simple and so quick and so accurate that I think it ought to become a regular exercise in engineering classes. The amount of accuracy is dependent simply upon the scale on which the drawing is made.

To illustrate the method, I give an example worked out by Mr. J. P. Fox last year. The periodic time was divided into 36 equal parts, and at each of these instants the value of the function was given. These instants are numbered 0, 1, 2, 3, &c. . . . 35. Calling the function $f(t)$ we have

$$f(t) = A_0 + A_1 \sin kt + B_1 \cos kt + A_2 \sin 2kt + B_2 \cos 2kt + \&c. \quad (1)$$

where k stands for $2\pi/T$, T being the periodic time. Mr. Fox did not find it necessary to draw the actual curve for $f(t)$.



To find A_0 it was only necessary to add up all the 36 given ordinates and divide by 36. It would have been a little more accurate to have found A_0, the average ordinate, by Simpson's rule or by actually plotting and finding the average height by the planimeter method. I see that Mr. Fox has not stated the value of A_0. Most English planimeters are graduated for square inches, so I will take it that the given ordinates are represented by so many inches. It is quite easy to multiply them by any number, and the answers found may be divided by this number.

To find A_1. The distance M N is the diameter of a circle (not shown on the figure) whose circumference is 36in. This circumference is divided into 36 equal parts. The points of division are marked 0, 1, 2, 3 . . . 35. Perpendiculars are drawn from each point to the diameter 0, 18. The feet of these perpendiculars are indicated by the corresponding figures, and this is how the straight line M N is marked out. Perpendiculars (I shall call them verticals) are raised from these points.

At any convenient place a straight line P Q is drawn at right angles to M N. In the figure it happens to be drawn from the middle of M N. The points 0, 1, 2, &c., marked on P Q are at distances from P which represent the given values of our function at the times 0, 1, 2, &c.

Project horizontally from 0 in P Q, and vertically from 0 in M N, and find the point of intersection. This is a point in the curve A_1. Project horizontally and vertically from the points 2, then 3, and so on, and in this way find 36 points in the curve A_1. Draw this curve in pencil. Carry the point of a planimeter from the 0 point, 1 point, 2 point, &c., to 0 again. Divide the area so found by 18, and the answer is the required value of A_1. It is to be generally understood that, although some areas are really negative and some positive, if the planimeter point be always carried round in the direction of increasing numbers the observer has no thinking to do—he has not to consider whether a particular loop is positive or negative.

To find B_1. As we have 36 intervals of time, and 9 is the quarter of 36 :—

Project horizontally from the points in the line P Q..	0	1	2	3	4	&c.
To meet verticals from the points in the line M N	9	10	11	12	13	&c.

Observe that in the line M N the point 0 may be called 36, the point 1 may be called 37, and so on.

The area of the curve B_1, which is found by joining the points of intersection, divided by 18, gives the value of B_1.

To find A_2 :—

Project horizontally from the points in P Q	0	1	2	3	4	&c.
To meet verticals from the points in the line M N	0	2	4	6	8	&c.

We thus find points in the curve A_2. The area of this curve divided by 36 gives the value of A_2.

To find B_2 :—

Project horizontally from the points in P Q	0	1	2	3	4	&c.
To meet verticals from the points in M N..	9	11	13	15	17	&c.

We thus find points in the curve B_2. The area of this curve divided by 36 gives the value of B_2.

Mr. Fox was told that these were the only terms, but if there had been more terms wanted—

To find A_3 :—

Project horizontally from the points in P Q	0	1	2	3	4	&c.
To meet verticals from the points in M N.	0	3	6	9	12	&c.

Divide the area of the resulting curve by 54 to find A_3.

To find B_3:—

Project horizontally from the points in P Q..	0	1	2	3	4	&c.
To meet verticals from the points in M N...	9	12	15	18	21	&c.

Divide the area of the resulting curve by 54 to find B_3.

Observe that if the circumference of the circle of which M N is a diameter is l inches, the successive divisors of the above areas are :—for A_1 and B_1, $\frac{1}{2} l$; for A_2 and B_2, l ; for A_n and B_n, $\frac{n}{2} l$.

The points in M N used to find A_n are numbered 0, n, $2n$, $3n$, &c. ; and for B_n they are $\frac{c}{4}$, $\frac{c}{4} + n$, $\frac{c}{4} + 2n$, $\frac{c}{4} + 3n$, &c. where c is the number of given ordinates. In our example c was 36.

When the coefficients up to A_6 and B_6 are wanted it is advisable to let c be at least 60.

Digitized by Google

If instead of the form (1) we wish to have the expansion in the form $f(t) = A_0 + a_1 \sin (k t + e_1) + a_2 \sin (k t + e_2) + \&c.$, it is only necessary to remember that $a_1 = \sqrt{A_1^2 + B_1^2}$ and $\tan \epsilon_1 = \frac{B_1}{A_1}$.

The above example was worked out by Mr. Fox in a time competition between him and another student who was practised in using a mechanical analyser.

Mr. Fox found $f(t) = A_0 + 4{\cdot}690 \sin \frac{2\pi}{T} t + 1{\cdot}744 \cos \frac{2\pi}{T} t + 1{\cdot}940 \sin \frac{4\pi}{T} t - 0{\cdot}328 \cos \frac{4\pi}{T} t$ in one hour and a-half from the time when he opened the envelope containing the 36 numerical values of the function. In another quarter of an hour he obtained the equivalent form,

$$f(t) = A_0 + 5{\cdot}003 \sin \left(\frac{2\pi}{T} t + 20^\circ{\cdot}38\right) + 1{\cdot}97 \sin \left(\frac{4\pi}{T} t - 9^\circ{\cdot}9\right).$$

The numbers given to the two competitors were calculated from

$$f(t) = A_0 + 5 \sin \left(\frac{2\pi}{T} t + 20^\circ\right) + 2 \sin \left(\frac{4\pi}{T} t - 10^\circ\right),$$

but I forget what was the particular value of A_0 used. The curves were inked in afterwards. It may be of use to the student if I give the areas found for the four curves. A_1 was 84·42 sq. in., B_1 was 31·41, A_2 was 69·88, and B_2 was $-11{\cdot}80$.

WAVE FORM SYNTHESIS.

BY JAMES MARK BARR, STANLEY BEETON, C. PERCY TAYLOR.

(*Concluded from page 260*).

SYNTHESIS OF WAVES.

It is obvious that the *experimental* method of attacking the subject with wave forms of predetermined shapes has every advantage. There are really two fields for work in alternate-current wave form synthesis: the one which takes up the subject classically and deals with the details of the theory of "injector waves," and the other which has to do with the immediate practical effects of a few typical shapes produced by trial methods and applied experimentally aside from any theoretical principles of wave synthesis. The first field is very broad, and requires for its development much time and detailed experiment. It would be necessary to work with a great number of wave forms, varying between wide limits of shape and differing consecutively among themselves by small variations of contour. We propose to confine ourselves in the present Papers to the second field of wave form synthesis, and aside from the experimental results with several particular wave shapes (which are to follow), we shall not go further than merely suggesting certain lines of classical study and experiment. However, certain rudimentary points in the theory of synthetic waves have inevitably presented themselves, and several essential principles of operation in the production of desired wave shapes have been roughly developed.

The results given below have been obtained in the laboratories of the Central Technical College and as stated, our preliminary results were got by the use of a Gramme dynamo and a two-part injector commutator. This first commutator was made of two parts, so that we could inject the resistance, inductance or capacity once in every half-wave, the armature giving one period per revolution.

Fig. 1 is a simple diagram of the arrangement.

The brushes b_1 b_2, which are set with any angle θ between them, bear upon the injector commutator J keyed to the dynamo shaft. When the slot between the two parts coincides with the line A B, then the electromotive force wave of the armature crosses the zero line. The angle ϕ between A B and the brush b_1 determines the *epoch* (as measured from the position of zero electromotive force) at which the resistance, inductance or capacity—connected across terminals T_1, T_2—is thrown into the armature circuit. The angle θ determines the duration of the effect. This we call the *interval*. A sufficient number of variations were produced by resistance and capacity, and we found it disadvantageous to use inductance on account of sparking at the injector.

It is possible to predict the potential difference wave resulting from the use of the "injector" with a known resistance or capacity to be taken at terminals of a given load, but the mathematical expressions for such predetermination are rather cumbersome. For *resistance* injection with non-inductive loads we have a graph consisting of two parts. Assuming the machine to give a sine wave expressed by $V = V_0 \sin p t$, the resultant graph coincides with this while the resistance is short-circuited. When resistance is in circuit we have $V = \frac{R}{R+r} V_0 \sin p t$ as the expression for the graph during the interval, where R is resistance of load and r is the injected resistance.

For capacity injected with non-inductive load the case is more complicated. Again, assuming the dynamo to give $V_1 = V_0 \sin pt$, the resultant graph again coincides with the curve given by the latter expression while the condenser is short-circuited.

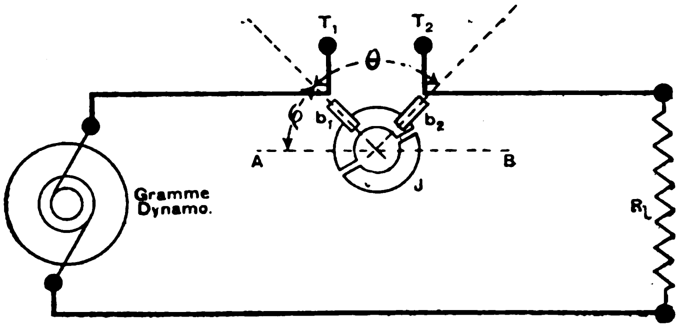


FIG. 1.

Let t_1 be the *epoch* as measured from the point of zero dynamo E.M.F. at which the condenser comes into the armature circuit, and let t be any point of time while the condenser remains in circuit. Then at the time t we shall have

$$V_1 = V + v, \quad \ldots\ldots \quad (a)$$

where V is the potential difference between the terminals of load and v the potential difference between the terminals of the condenser. If C is the current, and K the capacity of the condenser, we also have

$$v = \frac{1}{K}\int_{t_1}^{t} C\,dt, \quad \ldots\ldots \quad (b)$$

and if R is the resistance of the load

$$C = \frac{V}{R}. \quad \ldots\ldots \quad (c)$$

Combining (a), (b), and (c), we have

$$V + \frac{1}{RK}\int_{t_1}^{t} V\,dt = V_0 \sin p t.$$

Differentiating,

$$\frac{dV}{dt} + \frac{V}{RK} = p V_0 \cos p t.$$

The solution of this differential equation is

$$V = V_0 \frac{p R K}{1 + p^2 R^2 K^2} (\cos p t - p R K \sin p t) + A e^{-\frac{t}{RK}}.$$

The value of the arbitrary constant A is determined by putting $V = V_0 \sin p t_1$ when $t = t_1$. This gives

$$A = V_0 e^{\frac{t_1}{RK}} \left[\sin p t_1 \left(1 + \frac{p^2 R^2 K^2}{1 + p^2 R^2 K^2}\right) - \frac{p R K \cos p t_1}{1 + p^2 R^2 K^2}\right].$$

Thus we have as our final solution

$$V = \frac{V_0}{1 + p^2 R^2 K^2} \Big\{ p R K (\cos p t - p R K \sin p t) + e^{\frac{t_1 - t}{RK}} [(1 + 2 p^2 R^2 K^2) \sin p t_1 - p R K \cos p t_1] \Big\},$$

this being the equation to the curve while the condenser remains in circuit. We have worked out approximate graphic

Digitized by Google

methods for predicting wave shapes; but we have not the space to give them in the present article.

For practical testing with these waves it is necessary to have a higher frequency than could be obtained from the two-pole Gramme, and we therefore made use of a Ferranti dynamo, at a frequency of 100 ∿.

As this machine gave eight periods per revolution, it was necessary to make an injector commutator (hereafter called the injector) of 16 parts, in order that we might have, as with the Gramme, one "injector effect" on each half-wave.

But by using more than one pair of brushes (b_1, b_2 in Fig. 1) one is able to have any number of "injector effects" on each half wave. Our final working arrangement is shown in Fig. 2. When the brushes b_1, b_2 are short-circuited as represented, the dynamo circuit includes a simple non-inductive load R_l, and a dynamometer D, the inductance of which is negligible. Across the terminals T_1, T_2 we place a resistance, R_j, or capacity,

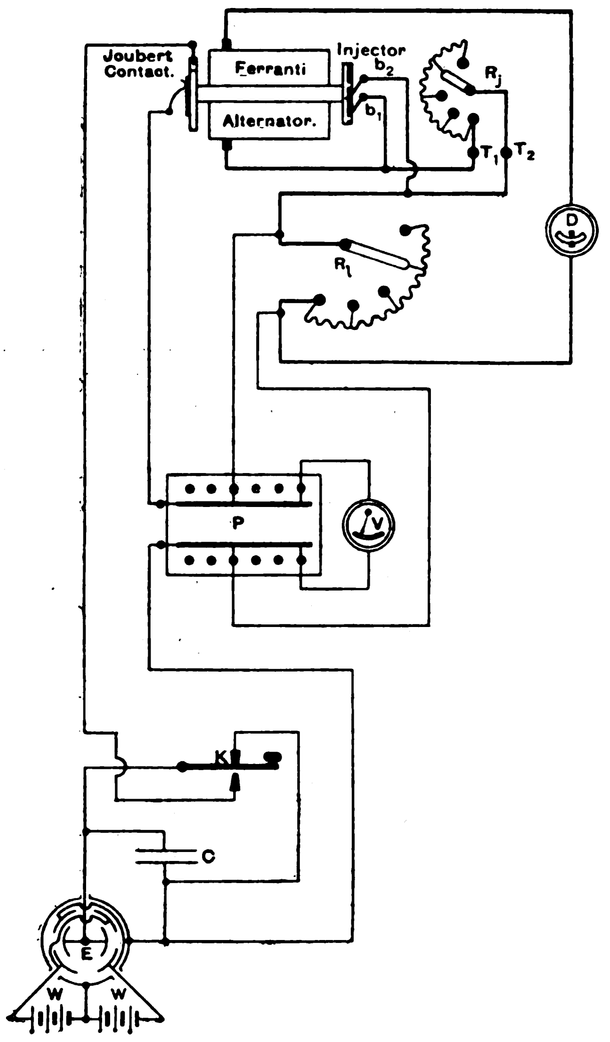

Fig. 2.

and this is thrown into the armature circuit during the interval when the brushes b_1 and b_2 bear upon separate segments of the "injector." The root-mean-square, of the amperes are read at D, and the the R.M.S. volts at the terminals of load are read at V, the voltmeter being connected through mercury contacts mounted on a paraffin block P as represented.

Two voltmeters were used at V (a Cardew and an Ayrton and Mather electrostatic instrument) in order to have check readings.

The readings of the instantaneous volts at terminals of load, from which we plotted our wave forms, were taken at E with an Ayrton and Mather quarter cylinder electrometer connected up as shown, and arranged to be intermittently connected across load by the usual form of Joubert rotating contact on the shaft of the alternator.

It may be of interest to call attention to the method adopted in connecting up the electrometer. If the development of both needle and quadrants is rectangular, we have :—

$$\text{Deflection} = k\,(a-b)\left(N - \frac{a+b}{2}\right), \quad . \quad . \quad . \quad (1)$$

where

N = potential of needle above case,
a = „ one pair of quarter cylinders,
b = „ the other „ „ „

and k is a constant depending upon the size of the needle and quadrants, their distance apart, and the control (torsional). In

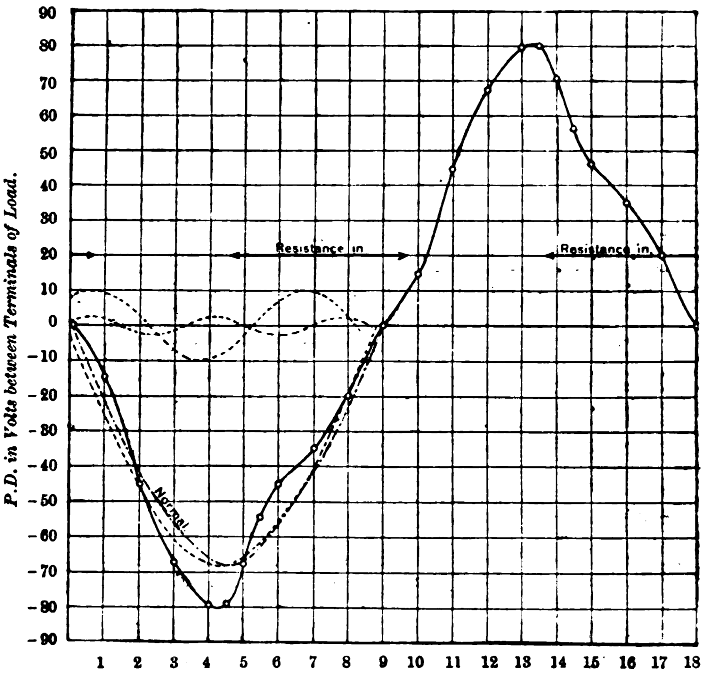

Fig. 3.—R.M.S. volts, 50. Resistance injected, 5 ohms. Load resistance (non-inductive), 6·86 ohms. Ferranti dynamo, 100 ∿ per second. Harmonics dotted.

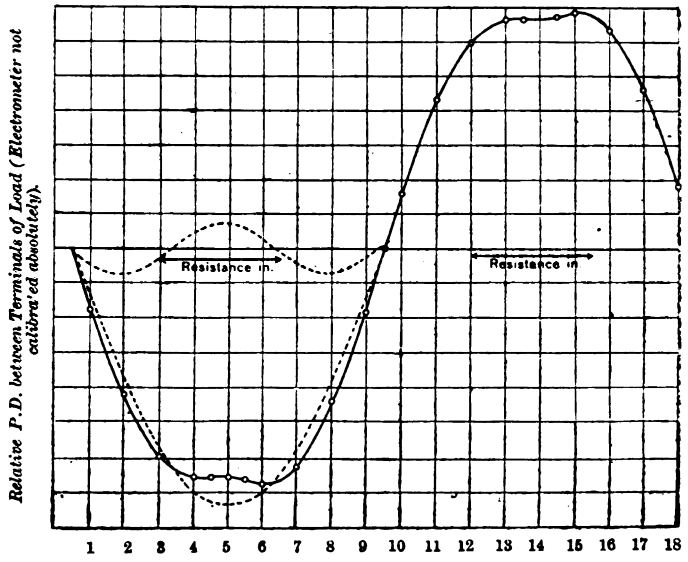

Fig. 4.—R.M.S. volts, 32. Resistance injected. 2 ohms. Load resistance, (non-inductive), 3·17 ohms. Gramme dynamo, 20 ∿ per second. Harmonics dotted. Normal coincident with fundamental harmonic.

the usual heterostatic method the needle is given a separate charge, *i.e.*, N is fixed, and the potential difference to be measured is that between a and b.

In these experiments a method due to Mr. Mather is used. We make $a = -b$ by connecting up the electrometer as described below, and so get rid of the $\frac{a+b}{2}$ in equation (1). We then have

$$\text{Deflection} = k\,(a-b)\,N, \quad . \quad . \quad . \quad . \quad (2)$$

Digitized by Google

so that the instrument has a straight line law. This is a great advantage for the readings of potential difference wave forms, because the low readings are got to the same degree of accuracy as the higher ones.

The connections used to obtain the above result are shown Fig. 2. The two pairs of quarter cylinders were charged by

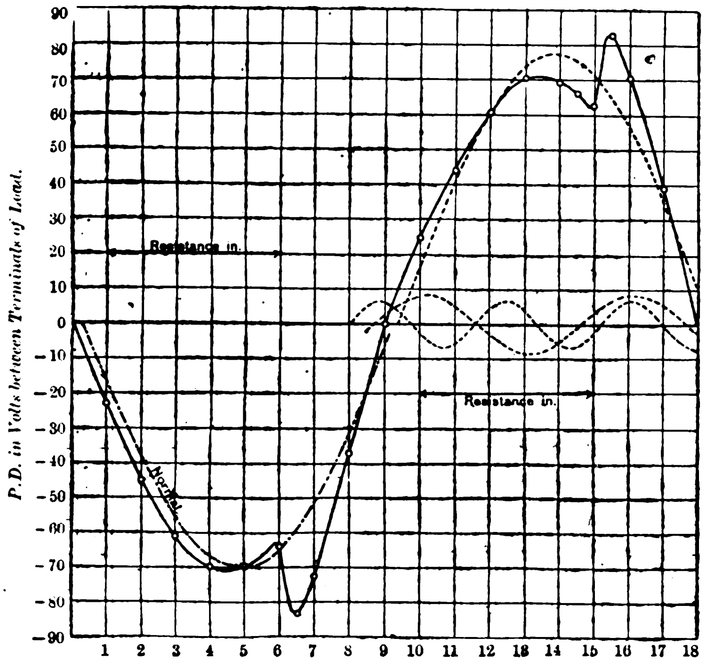

Fig. 5.—Resistance injected, 5 ohms. Load resistance (non-inductive), 6·86 ohms. Ferranti Dynamo, 100 ∿ per second. Harmonics dotted.

means of water cells, and the middle point of the set was joined to the case in order to get $a = -b$. Another advantage of this method is that equation (2) gives greater sensibility than (1) with the same auxiliary charge, because N is necessarily greater than $\left(N - \frac{a+b}{2}\right)$.

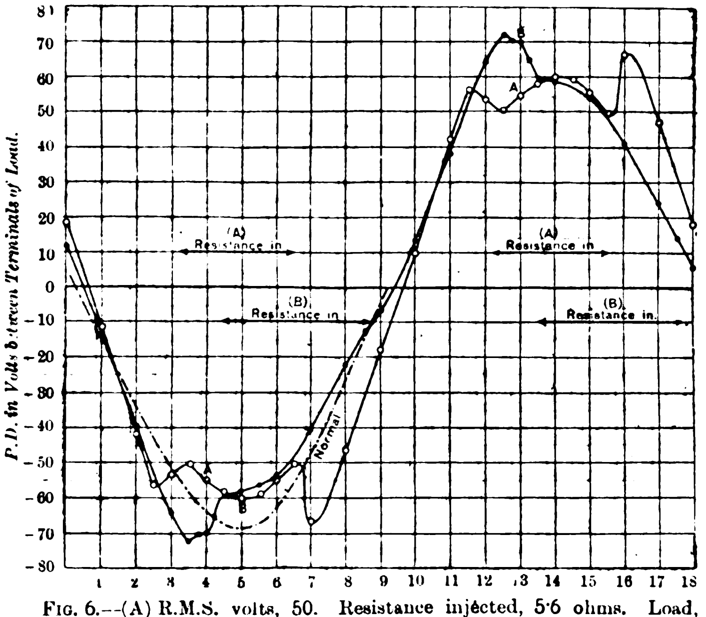

Fig. 6.—(A) R.M.S. volts, 50. Resistance injected, 5·6 ohms. Load, 8·43 ohms in parallel with primary of transformer taking about 1 ampere magnetising current. (B) R.M.S. volts, 50. Injected resistance, 5·60 ohms. Load, 11·43 ohms in parallel with transformer as above. Ferranti dynamo, 100 ∿ per second.

The wave forms of potential difference obtained with the arrangement shown in Fig. 2, are given below, together with the first two shapes (Figs. 4 and 7) got with the Gramme machine.

The dotted curves on these and the other figures are the more important harmonic components into which we have resolved the experimental curves by means of the analyser mentioned in the first part of this article. The normal potential difference wave of the machine is also shown and marked as such in each figure.

As mentioned above one really deals in this method, for resistance injected, with two graphs—the normal wave form of the dynamo as running without injector, and the normal graph on the load as it would be were the resistance at the injector con-

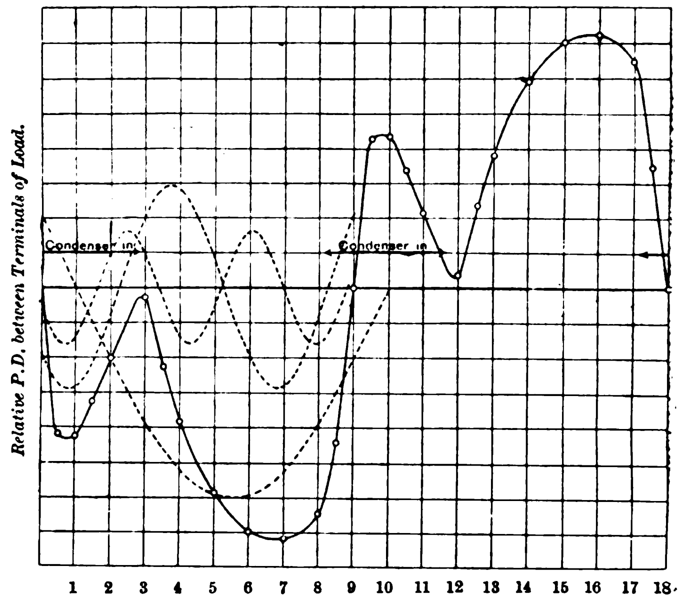

Fig. 7.—R.M.S. volts, 30. Injected capacity, 220 microfarads. Load resistance (non-inductive), 3·17 ohms. Gramme dynamo, 20 ∿ per second.

tinuously in the circuit. We have found that, as would be expected, the wave form resulting from the use of the injector has as its limiting contours the two virtual graphs just referred to. Thus the resultant potential difference or current waves, when there is no inductance in the circuit, change instantly from one of the virtual graphs to the other, according to the epochs and intervals of the injector. When inductance is present we have to remember the law of current rush, and

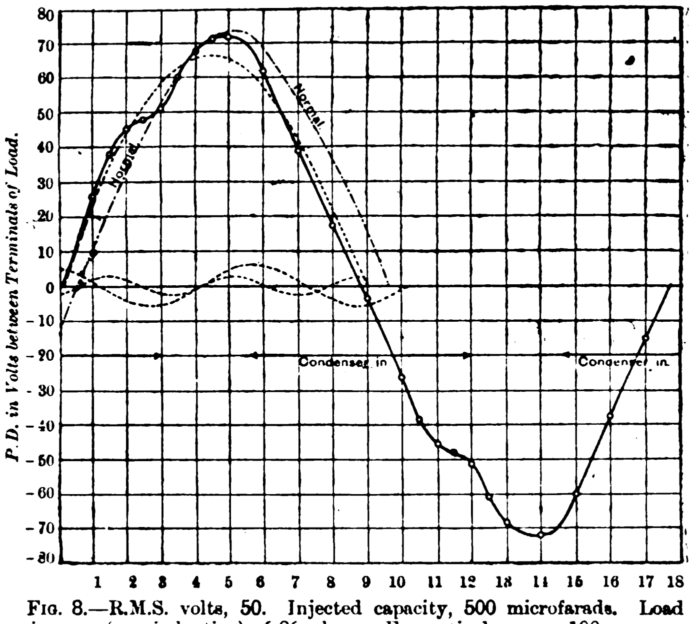

Fig. 8.—R.M.S. volts, 50. Injected capacity, 500 microfarads. Load resistance (non-inductive), 6·86 ohms. Ferranti dynamo, 100 ∿ per second. Harmonics dotted.

we observe in such cases that there is an assymptotic rush from one graph to the other. Figs. 5 and 6 well illustrate these points. In Fig. 5, from contacts 6 to 10 and 15 to 1, the graph is a portion of a sine curve which would have a maximum ordinate of over 100 volts, and during the interval (contacts

Digitized by Google

Nos. 1 to 6 and 10 to 15) the graph is part of a sine wave having a maximum ordinate of 71 volts. The root-mean-square value of this wave is rather higher than 50 volts, but in all of our actual tests with irregular forms we keep all waves at the uniform value of 50 R.M.S. volts.

In Fig. 6 (A) we show a wave produced by injection of resistance in the middle of the half-period, as indicated in the figure. In this case we had considerable inductance in the circuit (the primary of a 1·5-kilowatt Mordey transformer), and the effect is shown in the irregularity of the peaks. In Fig. 6 (B) we show a wave of the same order as Fig. 5, and this wave also was taken at the transformer terminals. It is interesting to note that this wave, which approximates to the characteristic shape of the Westinghouse (Stanley) alternate-current arc dynamo, likewise exhibits at the peaks the curious dip or point of inflection to be observed with the Stanley machine. Fearing that these dips were due to false readings, we repeated our observations many times at the peak values, but we found that the inflection was always present.

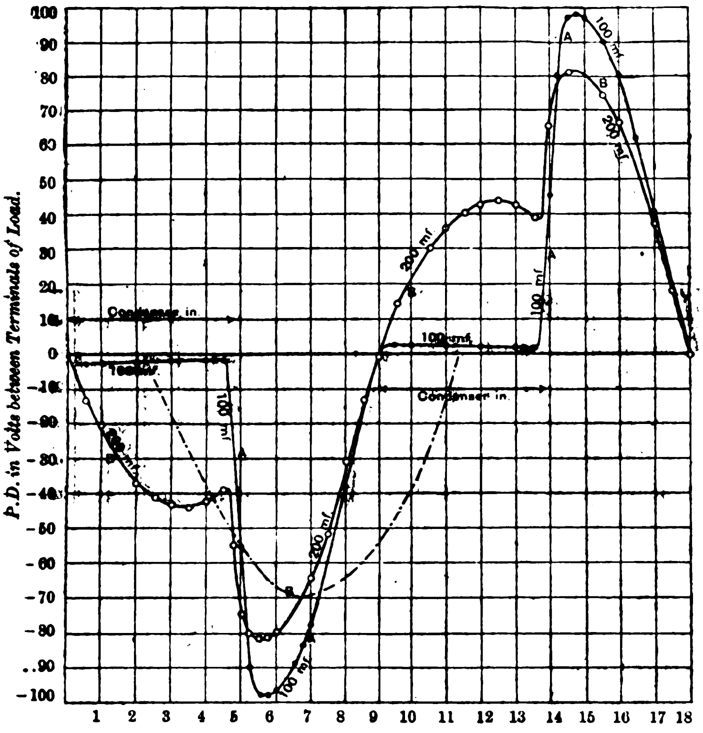

FIG. 9.—Waves of equal R.M.S. volts, showing variation of effect with change of capacity injected for same interval and at same epoch. (A) 100 microfarads injected. (B) 200 microfarads injected. R.M.S. volts, 50. Load resistance (non-inductive), 6·86 ohms. Ferranti dynamo, 100 ∿ per second.

Fig. 4 shows another wave, with the injection at the middle of the half period. Due to uncertain contact and sparking, the resistance came on and went out gradually; and, besides this, the Gramme armature had appreciable self-induction. Hence the rush from one virtual graph to the other is not as marked as in Fig. 6 (A). Fig. 3 shows the effect of injecting resistance during an interval which extends on both sides of the zero point of the potential difference. This gives a wave high in the middle of the half-period. With such waves the rush from one virtual graph to the other is not so easily discerned as in the case of injection at the middle of half-period. Another point to be observed in connection with resistance injection is that if we remove resistance from the circuit at a point near the zero of the wave, there is not much change to be observed in the resultant graph in the neighbourhood of this point. Resistance injection is very useful for obtaining peaked waves, but unless we make several successive injections in each half-period it is difficult to obtain flat-topped waves. Thus far, we have dealt chiefly with peaked forms, as flat-topped waves are most easily produced by using a revolving contact maker which periodically reverses a constant potential difference. This arrangement gives us a rectangular wave, and we shall publish the results of tests with this shape in a later article. However, as will be shown below, it is possible to produce flat-topped waves from a sine shape by the use of condensers.

The effect of injected capacity on the graph is due to the gradual rising of the potential difference between the terminals of the condenser as the charge increases, thus causing a lowering of the curve of potential difference between the ends of the load; but after the curve crosses the zero line, the potential difference between the terminals of the condenser is added to that between the terminals of the dynamo This addition gradually lessens in effect as the charge goes down. This is clearly illustrated in Fig. 8, but it is to be noted in this case that the condenser was short-circuited before the charge was much reduced. In Fig. 9 we show the alteration of effects for different injected capacities for the same epoch and interval. It is seen that if we have an infinitely large capacity its injection has no effect, and the machine wave remains normal. As the other limit, if we have a zero capacity the graph follows the zero line during the interval. In the 100 microfarad curve (Fig. 9) the capacity is so small that the potential difference at the condenser terminals remains practically equal to that of the dynamo during the whole interval, whence the resultant potential difference is

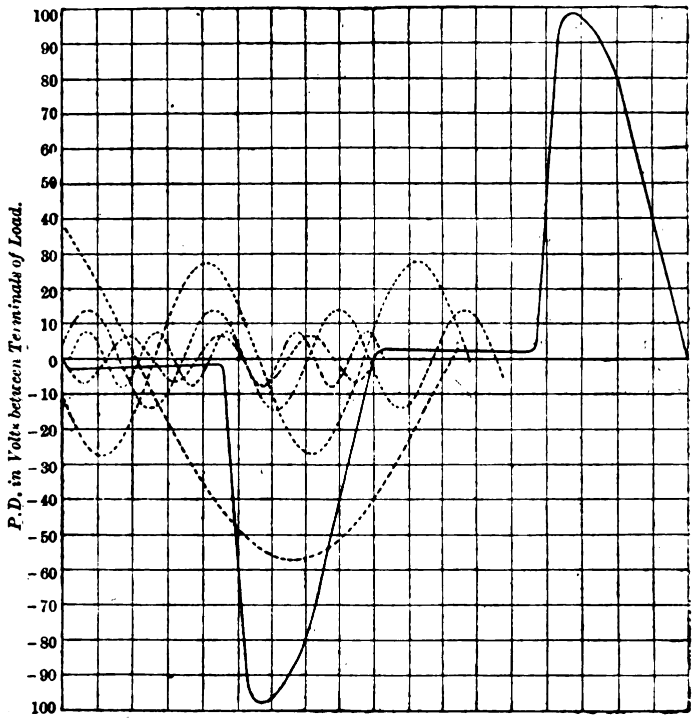

FIG. 10.—Showing harmonic analysis of curve A, Fig. 9.

almost nought. With the 200 microfarads injected we should have had the same result if the load resistance had been reduced in the same proportion as the capacity was increased. But this resistance was kept the same, and hence the condenser charge, and the potential difference at its terminals, did not increase so rapidly as the dynamo potential difference. Thus the graph is higher during the interval in this case.

For capacity injection with an inductive load the effect is different, owing to the fact that the current is no longer in phase with the potential difference at the terminals of load. Fig. 12 shows graphs of potential difference and current taken on a 3-kilowatt Mordey transformer (open secondary), with 100 microfarads injected. In this case, since the current does not follow the potential difference wave, but keeps a nearly constant value during a good part of the interval, the charge continues to increase at a rapid rate, whence the condenser potential difference becomes greater than the dynamo potential difference, and therefore the resultant graph crosses the zero line. By making the epoch earlier and the injected capacity greater, thus getting a less rapid lowering of the graph, we obtain a flat-topped wave.

For a number of the curves shown we have given the virtual Fourier harmonics present in the graphs, as they serve to indi-

Digitized by Google

cate the deviations from the fundamental sine wave, and also as they are useful in the consideration of resonant effects and motor problems.

We have read with interest of Dr. Fleming's ingenious method for obtaining the root-mean-square values of plotted wave forms; but we think that as long as an Amsler

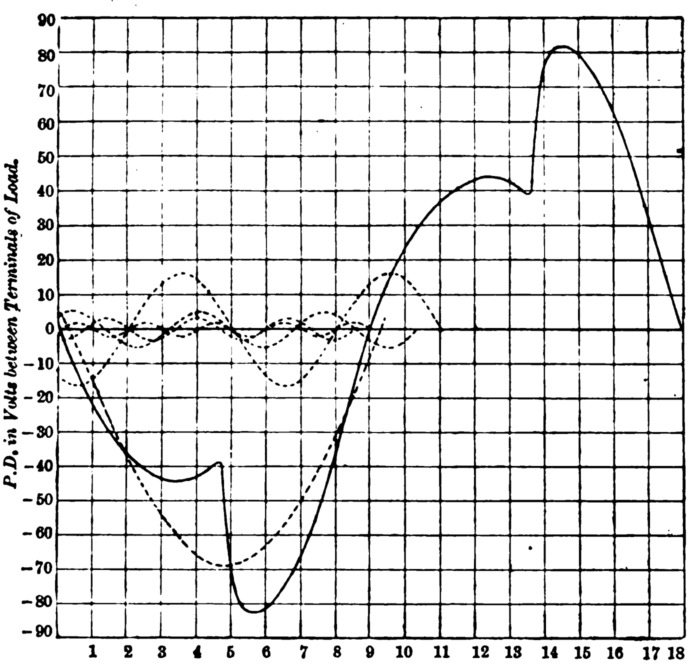

FIG. 11.—Showing harmonic analysis of curve B, Fig. 9.

area planimeter is required in connection with the polar plotting, one might as well use an Amsler first-moment planimeter with the usual rectangular co-ordinate wave form. We have found it most advantageous to retain the distinct advantages of rectangular plotting and to use the latter instru-

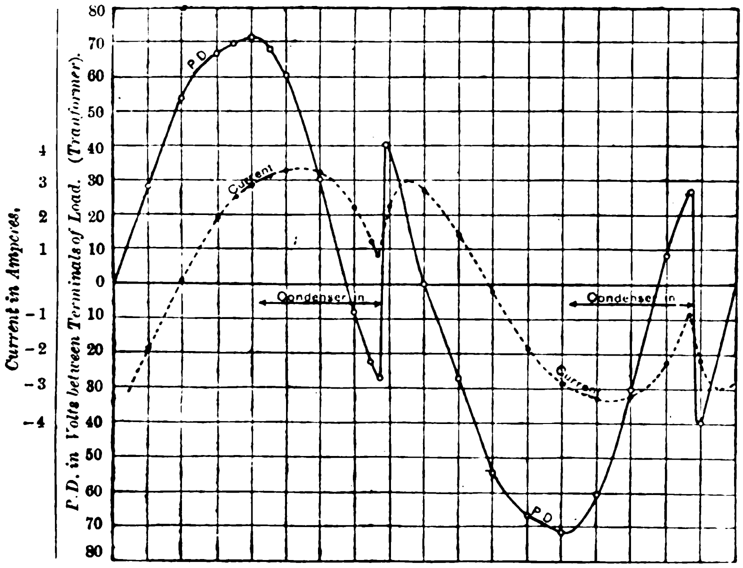

FIG. 12.—R.M.S. volts, 46. Amperes, 2·5. Injected capacity, 100 microfarads. Load, primary of transformer. Ferranti dynamo, 100 ∾ per second.

ment. This instrument, with one tracing over the ordinary curve, gives the value of the integral $\frac{1}{2}\int_0^T y^2\,dt$, the first moment of the ordinates, and $\sqrt{\frac{1}{T}\int_0^T y^2\,dt}$ is the root-mean-square value.

The experimental work has been carried out at the Central Technical College, as mentioned, where, due to the courtesy and kind interest of Prof. Ayrton and Mr. Mather, we have had excellent facilities. We have been especially fortunate in having at our disposal an aggregate condenser capacity of nearly 1,200 microfarads.

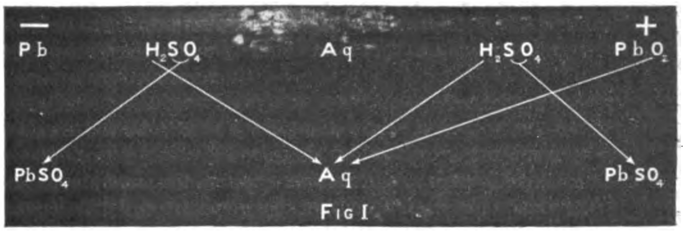
At present we are making some tests on transformers with various wave shapes, and we hope shortly to publish our results.

THE ELECTRO-CHEMICAL REACTIONS IN SECONDARY CELLS.

BY W. R. COOPER, M.A.

In a Paper which appeared towards the close of the past year in Wiedemann's *Annalen*,* the well-known double-sulphating theory of secondary cells received fresh support from Herr F. Streintz, whose views have since aroused adverse criticism from the pen of M. G. Darrieus in a recent number of *L'Electricien*.† We propose to briefly consider the two articles referred to.

Assuming that the energy of the cell is due only to the salts formed at the expense of the sulphuric acid, Herr Streintz represents the electrolytic changes on discharge in the following way :—



In this representation of the reactions no account is taken of the formation of plumbic acid, H_2PbO_3, of hydrogen absorbed by the negative plate, or of the liberation of gases in the free state.

In order to calculate the E.M.F. of the cell from thermochemical data, the electrolytic changes are considered to take place in three successive stages. First, water is decomposed by the liberated SO_4 of the sulphuric acid, the latter being reformed. There is thus an absorption of heat equivalent to that represented by the numerical part of the equation—

$$H_2O = H_2 + O - 68{,}400 \quad . \quad . \quad . \quad . \quad . \quad (1)$$

Oxidation of the negative plate, and reduction of the positive, both to the form of monoxide, result from the liberated oxygen and hydrogen, and there is a consequent evolution of heat according to the equations—

$$\left.\begin{array}{l}\overset{-}{Pb} + O = PbO + 50{,}300 \\ \overset{+}{PbO_2} + H_2 = PbO + H_2O + \alpha\end{array}\right\} \quad . \quad . \quad . \quad . \quad . \quad (2)$$

The quantity α is unknown.

Since the metallic oxides cannot exist in the presence of free acid, there is finally an evolution of heat due to the formation of lead sulphate on both plates, according to the equations—

$$\left.\begin{array}{l}\overset{-}{PbO} + H_2SO_4Aq = PbSO_4 + Aq + 23{,}400 \\ \overset{+}{PbO} + H_2SO_4Aq = PbSO_4 + Aq + 23{,}400\end{array}\right\} \quad . \quad . \quad . \quad (3)$$

The thermo-chemical data employed are those given by Ostwald, expressed in calories.

The total electro-chemical change is, therefore, represented by the equation—

$$\overset{-}{Pb} + 2H_2SO_4Aq + \overset{+}{PbO_2} = 2PbSO_4 + Aq + (\alpha + 28{,}700),$$

and the E.M.F. is represented by an evolution of heat amounting to $(\alpha + 28{,}700)$ units.

The quantity α was indirectly determined by a method which need not here be fully considered. It depends upon the measurement of the heat evolved on the conversion of lead peroxide into lead sulphate by the action of sulphurous acid in the presence of hydrochloric acid. This was carried out in a manner due to Nernst. The result arrived at is vitiated to

* Wiedemann's *Annalen*, October, 1894. † *L'Electricien*, May 18, 1895.

Digitized by Google

some extent by the fact that a part of the lead sulphate formed is converted into acid salts. By means of equations connecting the quantity so obtained with a, and involving known thermo-chemical data, the value of a is deduced to be +58,300 heat units.

Thus the total heat evolved in the electro-chemical changes considered is represented by 87,000 units. Assuming the number of coulombs per gramme of hydrogen to be equal to 96,540, and the joule to be equivalent to 0·239 heat units, then, lead being divalent, 46,150 calories correspond to one volt, and the E.M.F. is given by $\frac{87,000}{46,150} = 1{\cdot}885$ volts.

The E.M.F. of a cell containing very dilute H_2SO_4 (sp. gr. 1·055) was found experimentally to be 1·900 volts, and the temperature coefficient of a similar cell was found to be +0·000140. It would thus appear that the E.M.F. of this cell, due to chemical energy alone, amounts to 1·860 volts, a result which is very close to that already found by calculation. Owing to the many errors that may be introduced in the determination of thermochemical data, Herr Streintz remarks in conclusion that the coincidence of these results may be partly due to a fortunate combination of circumstances, but that the investigation should nevertheless serve to show that the reactions may be represented in a simple manner.

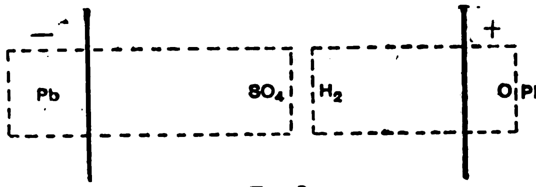


FIG. 2.

M. Darrieus in *L'Electricien* opposes the above theory, and denies the statement *that the metallic oxides cannot exist in the presence of free acid.* The results of experiments are given showing that lead monoxide, remaining for two days in sulphuric acid of various degrees of concentration, was only partly converted into sulphate. Whence it would appear that the double-sulphating theory, as put forward by Messrs. Gladstone and Hibbert and others, is untenable. It has also been observed that the amount of sulphate upon the positive plate is a variable quantity, a result which is easily explained by this limited action of the acid.

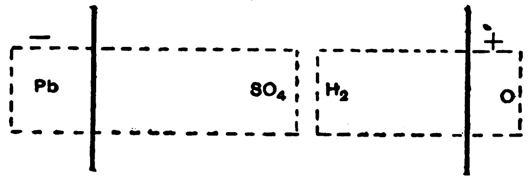

FIG. 3.

That such a theory has arisen is due solely to the desire to apply Thomson's law to the cell at any price, and it is wholly contrary to all laws of electrolysis. In conclusion, M. Darrieus observes that this is altogether unnecessary if only the characteristic properties of the active material on the negative plate be considered.

To us it does not appear that the experimental determination of the amount of lead sulphate formed by the action of sulphuric acid on lead monoxide fulfils the required conditions for a crucial experiment. Unless the litharge were in a fine state of subdivision, it is improbable that the whole would be converted into lead sulphate, because this insoluble compound would form an exterior protective coating upon the particles, thus preventing further action of the acid. But in the electrolytic actions considered we have first the reduction of the lead peroxide by the hydrogen, and it is reasonable to suppose that where such reduction can take place free acid is present, and would also form the sulphate. Owing, however, to the continual formation of water by both reactions, and consequent weakening of the acid, the sulphate formed would be expected to be variable in amount.

There are, however, other reasons for strongly doubting the validity of the double-sulphating theory. The semi-graphical equation which is given by Herr Streintz at the beginning of his Paper can only be regarded as misleading. The first molecule of sulphuric acid may be considered to act in the usual way, as indicated by the diagram (Fig. 2). But how is the action of the second molecule of acid to be represented? The ions H_2 and SO_4 are both required at the same plate.

There is a tendency at the present time to discard the distinction between primary and secondary reactions. This is chiefly due to a confused idea of what constitutes either of these classes. No electrical energy can be given to the circuit by a chemical change without the liberation or separation of an ion. In considering the action of the second molecule of sulphuric acid, we may look upon the PbO as equivalent to two poles of a cell, one of Pb, the other of O. The sulphuric acid is broken up, the SO_4 passing to the Pb to form sulphate, the H_2 passing to the O to form water, according to the diagram (Fig. 3). If the Pb is brought sufficiently near to the O, we have a molecule of PbO. In that circuit there may be electrical energy due to the reaction, but it is a closed circuit contributing nothing to the energy of the cell.

The solution of the difficulty appears rather to lie in considering the true nature of the negative plate. M. Darrieus * has found that if spongy, or reduced, lead be substituted for zinc in a Daniell cell, the E.M.F. is 0·68 volt, whereas the calculated value is only 0·3 volt. He therefore infers, since the action of a Daniell cell is simple, and satisfies Thomson's law, that the negative plate of a secondary cell consists of lead having a different molecular condition, or of an allotropic modification such that its reducing powers are greater than the ordinary lead for which heats of combination have been found. A correction amounting to 0·34 volt should, therefore, be added to the calculated values in such cases. For example, the E.M.F. of a secondary cell, calculated on the assumption that only one molecule of sulphuric acid is concerned, assumes the value 1·6 (as given by M. Darrieus), which is increased by the above correction to 1·94 volts.

It is not improbable that further research in this direction may place the matter on a more satisfactory footing than has hitherto been possible.

NOTES ON SOME EXPERIMENTS WITH ELECTROMAGNETIC MECHANISM.

BY P. V. McMAHON.

In publishing the following notes on some experiments made with electromagnetic apparatus, I do not lay claim to bringing forward anything of great importance or novelty, although some of the apparatus made and experimented with are, so far as I am aware, new. My aim in these researches was to arrive at an electromagnetic apparatus corresponding to an ammeter or voltmeter, but instead of moving a pointer over a scale, a mechanism was required capable of moving over a wide range with considerable force, while responding instantaneously to any variation in the electromotive force or current, as the case might be; further, the distance moved had to be directly proportional to the increase or decrease of ampere-turns. In fact, the apparatus was required to have a wide range, maximum strength and maximum sensitiveness—a combination which is almost impossible, as any person who has experimented in this direction can easily see. I regret to say the experiments have not been altogether satisfactory, but a fair amount of success has been achieved, and in bringing the results forward I hope they may be of some assistance to those working in the same direction. If when the experiments were started the same amount of data had been at hand, in all probability more satisfactory results would have been obtained in less time. The experiments will be given in the order in which they were made, the first being the simple solenoid and core.

The solenoid was 7in. long and $4\frac{1}{3}$in. diameter over flanges, contained 613 turns of No. 12 B.W.G. acc. copper wire, and had a resistance of ·39 ohms.

* *L'Electricien*, 2nd series, Vol. VIII., p. 237.

Digitized by Google

The core in the first experiment was $13\frac{1}{2}$in. long, $\frac{29}{32}$in. diameter, cone-shaped at the point for a distance of 4in. down. In the second set of experiments with this core, which I shall call No. 1, an iron jacket or band enclosed the coil. This jacket was $1\frac{3}{4}$in. wide by $\frac{5}{8}$in. thick, had a hole top and bottom $1\frac{5}{16}$ diameter to allow plenty of clearance for the core, and could easily be slipped into and out of position on the coil.

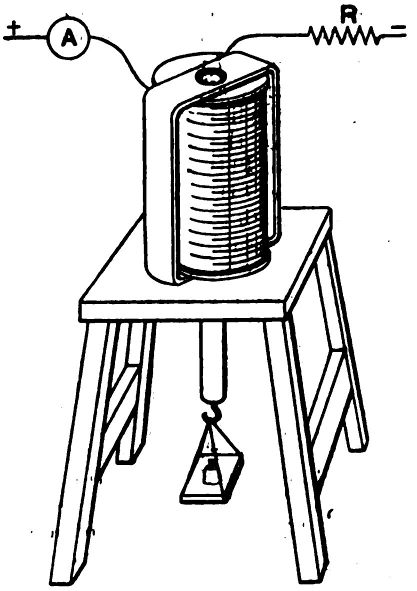

Fig. 1.

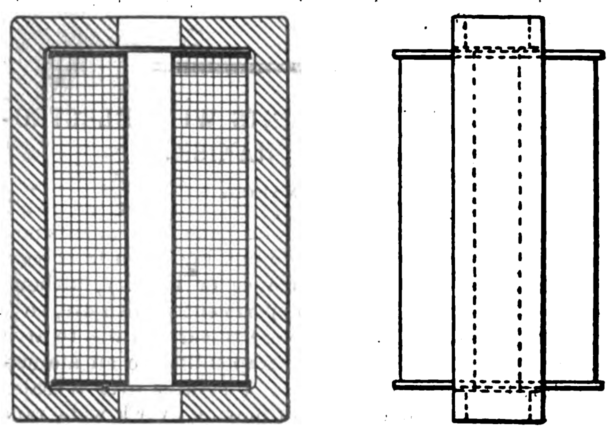
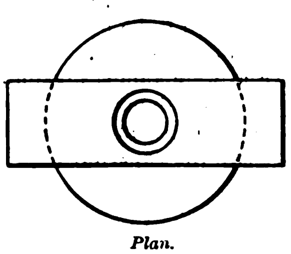
The core and jacket were of best Lowmoor iron, as, in fact, was all iron used in these experiments.

A quarter-size scale drawing is given of solenoid and jacket (Fig. 2) and No. 1 core (Fig. 3). Fig. 1 shows the general arrangement of experiment.

Section through Iron-clad Coil. *Elevation.*





Plan.

Fig. 2.—¼ Full Size.

The curve A gives ampere-turns and travel of core, with scale pan attached weighing 36oz. With 2,630 ampere-turns the point of the core was just flush with the top of the coil. In this position there was balance, and fewer ampere-turns would not support the core. Increasing the current gradually, we obtain points for curve A (Fig. 4), which is nearly a straight line for a range of 2in., and then bends off somewhat like the B-H curve for magnetisation of iron. A variation of 9,870 ampere turns gives a travel of 3·18in., lifting a weight of 36oz., scale pan included (of this weight the core was 31oz.). The core responded to the variation of current almost instantaneously.

Increasing the weight to 47oz. and varying the current as before, we obtain the curve B, with 3,750 ampere turns, and point of core flush with top of coil; balance was obtained as in A. Increasing ampere turns to 12,500, a travel of 2·95in. was obtained, or 2·95in. for a variation of 8,750 ampere turns, and an increase in weight of 23·4 per cent. Compare this curve (B) with B_1, in which the solenoid was ironclad, having same weight to lift; the travel is reduced, and the core point was 1·2in. outside top of coil. With 2,630 ampere turns a less number could not be obtained, as the ammeter readings were not reliable below 5 amperes, and the magnetisation was not increased beyond 9,000 ampere turns, as the core kept sticking to the sides of the solenoid for higher readings. Here for a variation of 6,370 ampere turns the core travelled 1·9in., as against 2·6in. for same variation of ampere turns. In this curve B_1, travel is more nearly proportional to the ampere turns; but the travel is less, and the arrangement is not

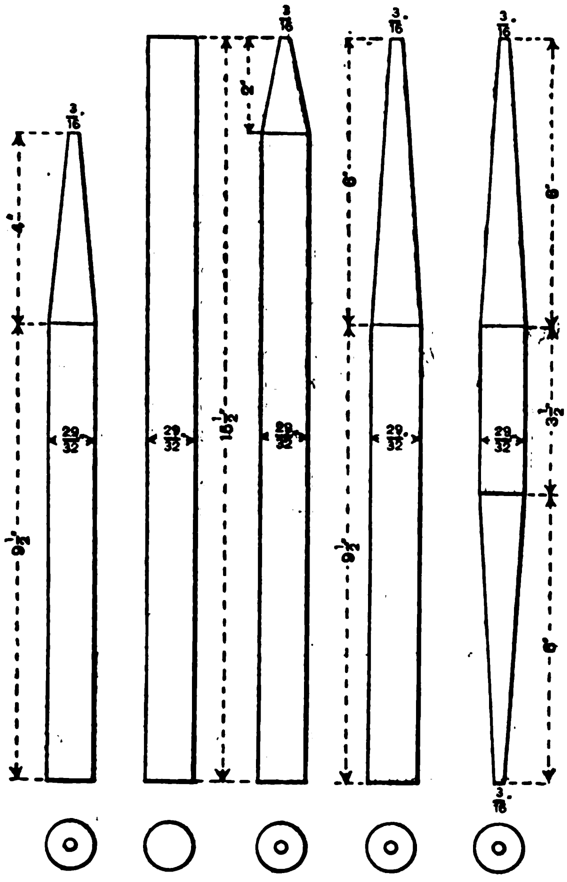


Fig. 3.

nearly as sensitive as in B curve. With the iron jacket, it seems as if the decrease of air gap between the cone-shaped point of the core and iron of jacket caused the core to move more than the action of the core and solenoid proper. In that case the length of the core would not affect the arrangement as long as there was sufficient iron to keep the lower air-gap constant, as shown in Fig. 4A.

Next the weight was increased to 84oz., and the result is shown in curve C with solenoid and core, and in C_1 with iron jacket over solenoid. In C for a variation of 5,500 ampere turns the core travelled 2·25in., and, as can be seen, the relation between the rate of travel and increase of current is fairly pro portional, the curve being nearly a straight line. In this, as in B, the arrangement was sensitive. The iron jacket was now placed around the solenoid and the curve C_1 obtained for the same variation of ampere turns, viz., 5,500, and same weight the travel being 2·4in.; the earlier part of the curve is straighter than in C, but then it becomes more curved towards the end of its

Digitized by Google

travel. The introduction of the iron jacket made the arrangement more sluggish as before, and this sluggishness became more apparent as the exciting power was increased. It can be noticed from the curves that in C_1 the core was 0·2in. outside coil before balance between weight and exciting power was obtained; without jacket this balance was obtained as the point of core was flush with top of coil.

The last experiment with this core (No. 1) the weight was increased to 180oz. Here the travel is much shorter, and it

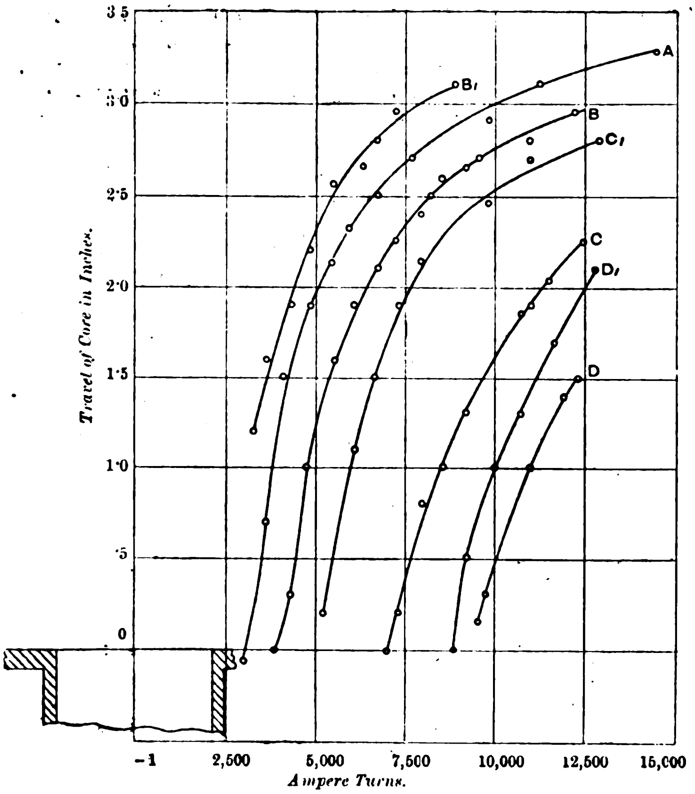

Fig. 4.

required a great deal more ampere-turns to support the weight. In D the travel was only 1·35in., and variation 3,000 ampere turns, the point of the core was ·15in. beyond the solenoid before balance was obtained. With the iron jacket and same weight and between same ampere turns variation the travel was 1·4in., or almost the same as without the jacket; but for a wider range of variation the travel was more. Another point worthy of notice is that the D_1 curve becomes straighter after the point of core is 0·5in. outside coil, and does not bend as in

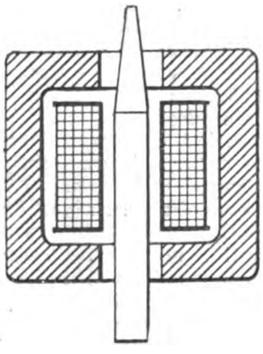

Fig. 4A.

B_1 or C_1. The use of the iron jacket again made the arrangement sluggish.

Tabulating result of the seven experiments with No. 1 core, and comparing results as to maximum travel, maximum sensitiveness and minimum variation of exciting power. A travel of 1·75in., one-fourth the length of the coil is taken as a standard, and for this travel all curves except B_1 and D are fairly straight, *i.e.*, the travel is very near proportional to the increase

Table I.—*Core 13½ long, tapered ¼in. at the top.*

—	Maximum travel.	Maximum ampere turns variation.	S i variation for 1¾in. travel.	Weight. Total.
A	3·15in.	9,870	1,750	36oz.
B	2·95in.	8,750	2,250	47oz.
B_1	1·9in.	6,370	4,750	47oz.
C	2·75in.	5,500	3,500	84oz.
C_1	2·55in.	7,250	2,500	84oz.
D	1·35in.	3,000	—	130oz.
D_1	2·0in.	3,700	3,500	130oz.

or decrease of exciting power between these limits. The curve A is the best: we have the smallest variation of ampere turns, and the arrangement is very sensitive, but in that case only a small weight was attached to the core, and consequently the power is small. In all cases the addition of the iron jacket made the arrangement sluggish, and therefore B_1, C_1 and D_1 can be struck out for want of sensitiveness. Turning our attention to A, B and C, we see that as the load is increased the required variation of exciting power increases in direct proportion, or the ratio of variation to load is practically a constant.

(To be continued.)

THE PERMANENT PROTECTION OF UNDERGROUND PIPES FROM ELECTROLYTIC CORROSION.*

BY HAROLD P. BROWN.

Some electric railway engineers insist that the only thing necessary to protect the pipes is to provide perfect bond wires between the rails, and plenty of feeder wires running from the dynamos to the rails. These are both of vital importance, as at present nearly half the energy generated by the railway dynamos at full load is wasted in merely overcoming the resistance of the conductors leading to and from the motor cars. But, assuming that the bond wires are perfect and the feeder wires ample, it is, of course, true that the current flowing on the pipes would be reduced, but they would still carry a considerable proportion and still suffer corrosion at the points where the current left them.

Referring to Fig. 1, we will suppose that R represents four continuous rails, each having a cross-section of 9 sq. in., or 36in. total. It will be found in nearly any city which meets modern requirements for gas and water service, that, considering the cross-section of metal of the pipes P in the network, under and parallel to the rails in the same and the two adjoining streets, it will amount to about 30 sq. in. The pipes are surrounded by the same moist earth that touches the rails, and they will, therefore, carry from *r r* to *t* 45 per cent. of the current, less the loss caused by the resistance of the earth at *r r* and *t*, and by the resistance of the pipe joints. To reduce this percentage one half would require rail feeder wires of 36 sq. in. cross-section, if iron, or 4 sq. in., if copper wires. Even with this enormous expense the rate of injury to the pipes would be reduced but one half.

Three-Wire System.—Another method of protecting the pipes which has been tried in a few small cities is an adaptation of Mr. Edison's three-wire system. This system is a great success when used for its intended purpose, the distribution of electrical energy for light and for power from stationary motors. Mr. Edison states that the use of this system for railways with bare overhead trolley wires will not protect the pipes for the reasons given below, and that it is extremely dangerous. In this system two sets of dynamos are used, as shown in Fig. 2. There are two trolley wires, T and T′, over each street. The negative pole *e* of the dynamo A is connected to T, while its positive pole *d* is connected to the wire *f* leading to the rails R, and also to *e′*, the negative pole of dynamo B, whose positive leads to T′. The current is supposed to leave dynamo B at *d′*, and pass through trolley wire T′ to one half the number of cars on the road. It divides at *r* between the rail R and the pipe P; returns to rail at *t*, passes through the other half of the cars on the road and returns over trolley wire T to dynamo A. If more of the cars C are running than cars D, the dynamo B would take the heavier load and the pipes would suffer at *t* and *t′*. If dynamo A had the heavier load, the pipes would suffer *t* and *r*. If both loads were balanced the pipes would suffer at *t*, which would be a constantly shifting point. The result would

* From the *Street Railway Review.*

Digitized by Google

be that the entire system of pipes would be corroded in the vicinity of any line of rails; that the total amount of corrosion would be somewhat reduced, but that it would be impossible to tell from electrical measurements on the surface of the street the condition of the pipes. The advocates of this system claim that when the number of cars is perfectly balanced between trolley wires T and T′ the pipes will not be damaged. This is not true, even though such balancing were possible, which it is not. Experience proves that even in an electric lighting station, it is extremely difficult to perfectly balance the lamps between the two dynamos. With trolley wire T over the up track and T′ over the down track, T′ would be overloaded when the heavy travel was down town in the morning, and *vice versâ*. It is, therefore, suggested that the two wires be divided between the two tracks, but there are serious practical difficulties in the way of this. The only advantage of this system would be the saving of copper wire to the railroad company. Its most serious disadvantage is the greatly increased fire risk, owing to the presence over each street of two bare trolley wires with 1,100 volts pressure between them. The ordinary trolley

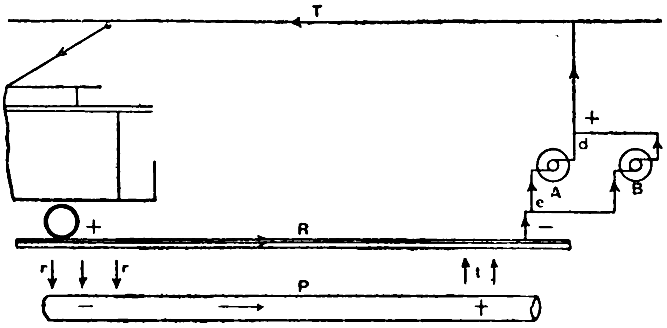

FIG. 1.

system is bad enough and difficult enough to maintain mechanically in position with 550 volts pressure between it and the ground; the double-trolley system is far worse in both respects, as it has two trolley wires which are supported by insulated hangers from the same set of span wires, and which have 550 volts between them. But the three-wire system, with its 1,100 volts between the two wires, is so much more dangerous and difficult to maintain, that the fire risk and serious inconvenience to firemen will cause city authorities and insurance boards to oppose it as soon as its character is understood. Its proper field may perhaps be on suburban roads, and even there the trolley wires, which are alongside of each other, should be of the same potential, the wires being joined to T in one section and to T′ in the next section. The Brooklyn strike was an object lesson of the difficulty in maintaining even a single-trolley wire against line cutters. But with this system a striker, unseen on a house top, could easily throw a weighted wire across both trolley wires, melting them instantly and dropping their ends in the street.

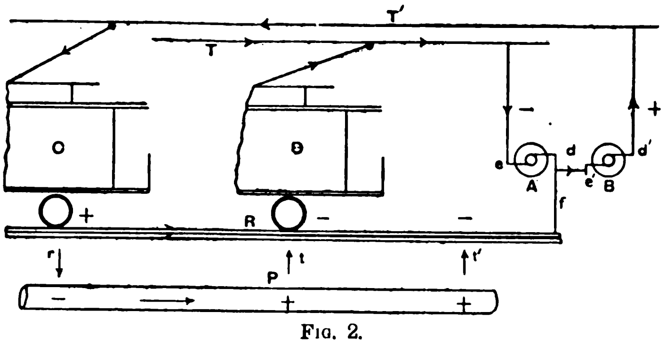

FIG. 2.

Insulated Rail Feeder Wires.—Some few engineers have insisted that running insulated feeder wires to the rails would protect the pipes. This, for the reasons given in the first paragraph, could not be of any help unless the rails also were insulated from the earth.

Pipe Feeder Wires.—Another scheme of pipe protection, frequently advocated in the past year, has two points in its favour, one of which, however, if true, is a serious reflection upon the condition of the road using it, and a rather grim joke upon the engineer advising it. It consists in connecting the negative terminal of the dynamos with a feed wire leading to the points upon the pipes which are positive to the rails. The theory advanced is that this connection will "make the pipes more negative than the rails." This ideal result is utterly impossible unless when broken or rusted bond wires are present in all four rails not far from the station. Referring again to Fig. 1, it is proposed to run a pipe feeder wire from the negative pole *e* of the dynamos to the pipes at *t*, where they are positive to the rails. This wire is supposed to "pump the current out of the pipes" and make them negative to the rail! Assuming, as before, that there are four continuous rails, or their copper equivalent, leading from *t* to the power house, and that, as is generally the case, one-third of the current is returning on the pipes from *r r* to *t*, a pipe feeder wire from the latter point to the station would require a cross-section of 18 sq. in., if iron, or 2 sq. in. if copper to make the pipes at *t* of the same potential as the rails at that point. But to make the pipes sufficiently negative to the rails, to be safe, this cross-section would need to be at least doubled. If, as was reported from one city whose pipes were "protected" in this way, the pipes were really negative to the rails when a connection of this kind was made with a wire of practical size, it is evident that the rail returns from that point were in so bad a condition that nearly 20 per cent. of the total energy was lost in going 1,500ft. from the power house. Protecting the pipes at such a tremendous cost might be worth while if it really did protect them, but it cannot do so for any definite period. The rail bonds are sure to be patched when they get very bad, and within a very short time the contact at *t* between the pipes and their feeder wire will become so poor that the old condition will reappear. Few electricians appreciate the difficulty of making and maintaining a good electrical contact between two different metals, even in a dry room. And still fewer have any idea of the tremendous difficulty in maintaining such a contact underground. For the past four years experiments have been under way at the Edison Laboratory to obtain between underground steel conductors a perfect electrical contact that would not be injured by water, acid, alkali, or mechanical movement. Every practical combination of metals, every method of joining, of excluding moisture, of providing for expansion and contraction, has been tested with heavy currents and then buried for the test of time. The conductors have been machined and scraped to an exact fit, bolted together under heavy pressure, plated with copper, tin or zinc, provided with sheet lead, tinfoil or other soft metal, or various non-oxidisable alloys placed under compression between the surfaces, covered heavily with paint or other water-repelling insulation; or a combination of several of these But time and heavy currents have caused the failure of every device with but a single exception, of which more later. When two different metals are joined in an electric circuit there are three sources of loss that must be encountered; first, the resistance of the metal itself; second, the contact or surface resistance, which can be somewhat reduced by increasing the pressure; and third, the thermo-electric loss. Electricians always calculate upon the first; sometimes give scant attention the second, but entirely ignore the third. Yet with heavy currents the total loss is often three times the amount due to the first alone. The causes and cure of these latter losses are outside the scope of this Paper; but the maintenance of an underground contact between a copper wire and a steel rail, or an iron or a lead pipe, is a problem that requires notice here. However ample the area of the contact between such surfaces; however great the pressure holding them together, and however careful the methods of excluding moisture, there are several agents of destruction constantly at work that are bound to succeed. Even when two iron plates are joined together in the best mechanical way and placed underground, their surfaces are sure to rust; oil or grease of course cannot be used between them. Even a thin film of iron oxide, on either surface, is of high electrical resistance, injures the conductivity of the joint, and permits the entrance of more and more moisture, thus causing further damage. But when a plate of iron and a plate of copper are bolted together and buried, the difficulties of maintaining an electrical contact are greatly increased. The two metals in contact with the moisture of the earth form a galvanic couple whose action corrodes the iron. The different ratios of expansion, due to increase of temperature from weather or current flow, breaks down both the contact and the protecting paint or other covering, letting in water. Therefore, any ordinary mechanical connection between an iron pipe and a copper wire is doomed to early destruction. In one city a pipe clamp is used in which lead is placed between the pipe and the clamp, and the whole insulated with cotton tape and black paint. It requires slight engineering skill to predict the life of painted cotton as a means of excluding water. And as for the lead, which is evidently used to secure a compression contact and save careful fitting of surfaces of pipe and clamp, it invites a still earlier destruction, since lead suffers more severely from electrolytic decomposition than iron or copper. And to further increase the resistance of the joint, the clamp is of iron, and is welded to the copper wire. Thus a pipe, which is already positive to the rails and suffering corrosion, is to be relieved by an insufficient feeder wire, and the current is invited to pass from iron to lead, from lead to iron, and from iron to copper, suffering a heavy loss at every contact, and making three joints where one is too many. With a copper

Digitized by Google

rod $\frac{5}{8}$ths of an inch in diameter and 30in. long, having a contact area of 10 times its cross-section against an iron plate, the surfaces being bright, accurately fitted and held together by very heavy pressure, the electrical loss was $\frac{8}{30}$ths of a volt with 1,200 amperes. In other words, with the best made mechanical joint between iron and copper, the loss was 0·426 E.H.P. Adding the other joints of equal area, iron to lead, and lead to iron, the loss was increased 20 per cent. It is evident that the engineer suggesting this joint has never tested it in heavy service with the proper instruments.

A Successful Method of Pipe Protection.—There are three problems to solve in protecting pipes from electrolytic corrosion:

First. To keep the pipes at least one volt negative to the rails at all points and at all times.

Second. To diminish as much as possible the flow of current on the pipes.

Third. To secure some permanent, inoxidisable contact of low resistance between the pipes and the necessary feeder wires.

In Fig. 3 A represents the main battery of dynamos whose positive poles d are joined to the trolley wire T, and whose negative poles e are connected to the rails R in the ordinary manner. These dynamos are adjusted to maintain the usual 550 volts pressure between d and e. The dynamo B represents at first about one-quarter of the total capacity of the station; but the proportion can be reduced when this plan has been put into service. Its positive pole d', is connected to trolley wire T; but its negative pole e' is connected by suitable feeder wires m to the points t on the pipes which were previously positive to the rails. The pressure of dynamo B is then so adjusted that it gives 5 to 12 volts more than dynamo A; as their positive poles are joined, this difference of pressure asserts itself by maintaining the pipes negative to the rails by 12 volts, less the previous positive charge and the loss incurred in passing the current through the feeder wire m. For instance, at Newark, N.J., the gas and water pipes were 7 volts positive to the rails at a point about 600ft. from one power house, and the service pipes and lead joints were seriously injured. The

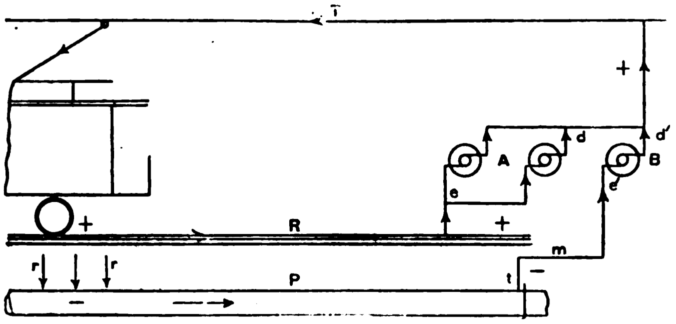

FIG. 3.

average current output of the dynamos was about 1,200 amperes, of which 400 returned by way of the pipes. The dynamos A were run at 550 volts, and by running the dynamos B at 562 volts, the point t on the pipes, which had been seven volts positive to the rails, was maintained at three volts negative, and all further corrosion checked. The closing of the circuit through m and dynamo B caused a drop averaging 60 H.P. in the station load. This was due to removing the resistance of the earth, which was encountered by the current in the pipes P in passing from t to the trolley wire T.

This method, as thus far described, entirely checks electrolysis of the pipes unless it be around some poor joint on same. Such a joint, however, can be easily detected by a low reading voltmeter on the surface of the street, and this action checked by continuing the wire m, diminished in size, to a point beyond the poor joint. It is true that as far as described the tendency of this method is to slightly increase the current flow on the pipes, but this is only the first step in the method. The current reaches the pipes at $r\ r$ near the ends of the railway lines, and here electrical measurements have shown in some cases at Newark that the rails were 15 volts positive to the pipes. This difference, of course, causes a large flow to the pipes, and is produced by poor bonds between the rails and insufficient rail feeders, or by the fact that the network of pipes may lead directly to the power house, while the lines of rails may take a roundabout course. But with proper bonding the difference of pressure between the pipes and rails at $r\ r$ may be brought down from 15 volts to 1 volt by carrying out from the higher pressure dynamo B a continuation of the wire m to the rails at $r\ r$. By this means, and by the proper feeder regulators in the wires m, the rails at r and the pipes at t, whose previous positive potential caused the current flow through the earth, can be made negative, and the current flow on the pipes cut down to a minimum. It was feared by some electricians that in order to keep dynamo B at a definite increase of pressure over the dynamo A, constant shifting of its rheostat would be necessary as the station load varied; or, that the dynamos would not regulate properly. No trouble has been encountered from either source with dynamos of two of the leading manufacturers.

This brings us to the third problem; a permanent, inoxidisable, elastic contact of low resistance between iron pipes and the feeder wires m, or between the meeting ends of steel rails, which contact shall possess an affinity for each metal. Here the writer has been permitted to share in, and to benefit from, the experiments leading in this direction, suggested by Mr. Edison, and carried on for the past four years. A few square inches on the top of the pipe is filed clean of paint or scale, and rubbed with a silvery metal compound, which at once turns any iron rust into pure metallic iron and amalgamates the surface. Metallurgists have long considered impossible a stable iron amalgam, but it nevertheless exists, and is so permanent that neither water nor any acid or alkali which it will encounter under the streets can decompose it or rust the iron surface beneath it. A U-shaped bolt is then slipped under the pipe, and a cast-iron yoke placed over it. The end of feeder wire m has been brazed to a copper saddle, $\frac{1}{8}$th of an inch thick, fitted between top of pipe and bottom of yoke. The centre of the saddle on each side of the wire is cut away to form a receptacle into which, after the copper has been amalgamated, is placed a plastic alloy of electrical origin. The nuts are then tightened up and locked. This alloy gradually hardens and expands, placing the joint under a tremendous pressure, and forming a perfect electrical contact of extremely low resistance, which will not corrode. Moreover, when a joint between iron and copper is thus prepared, all of the contact resistance disappears, and the thermo-electric loss is much reduced. But when this alloy is used between iron or steel surfaces both contact resistance and thermo-electric loss are eliminated. It will give a comparative idea of the efficiency of these contacts to state that, with a copper rod $\frac{5}{8}$ths of an inch in diameter and 30in. long, having an area of ten times its cross-section, in contact with a steel plate, with surfaces accurately fitted together and joined with great pressure, the loss in transmitting amperes was $\frac{24}{120}$ volts. The same with amalgamated surfaces, and with the plastic alloy between steel and copper was $\frac{13}{120}$ volts. With the plastic alloy between amalgamated surfaces of steel and steel it was but $\frac{4}{120}$ volts. Galvanometer tests of joints for heavy currents are, of course, worthless, as they do not show working conditions.

A large number of these joints were put underground about four years ago in order to make a thorough test. Measurements recently made with heavy currents show absolutely no deterioration. Many of them have been taken up, and no trace of oxidation was found, the surfaces being perfectly bright. Thus has the third problem in the way of permanent pipe protection been solved, and its prompt application will save money to water, gas, and subway companies, and to the electric railways.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, June 28th.

PHYSICAL SOCIETY.

5 p.m. Meeting at Burlington House. Papers to be read: (1) "An Electromagnetic Effect," by F. W. Bowden; (2) "On Synchronous Motors," by W. G. Rhodes; (3) "The Electrical Properties of Selenium," by Shelford Bidwell, F.R.S.

MONDAY, July 1st.

5 p.m. General Monthly Meeting.

WEDNESDAY, July 3rd.

INSTITUTION OF ELECTRICAL ENGINEERS.

9 p.m. Annual Conversazione in the Galleries of the Royal Institute of Painters in Water Colours, 191, Piccadilly.

Electric Welding in Ships.—In the adjourned discussion on electric welding, at a recent meeting of the North-East Coast Institution of Engineers and Shipbuilders, Mr. H. Macoll said it was a matter of regret that, although such a fitting as a boiler furnace might be welded from end to end with approval by one of the Government Departments which was supposed to concern itself with the safety and efficiency of marine engines in vessels carrying passengers at sea, yet on no account must the smallest portion of the steel working parts of a marine engine be welded if the structure was to obtain a passenger certificate.

SPECIAL NOTICE.

With this week's number of "THE ELECTRICIAN" is issued (gratis) Supplement Sheet Tables showing Total Capital Outlay and Receipts and Expenditure for the year 1894 of the Statutory Electric Supply Undertakings of the Metropolis.

Complaints of non-receipt should be promptly addressed to the Publisher.

THE LONDON ELECTRIC SUPPLY BUSINESS IN 1894.

Statistics, like mathematics, are an extremely dangerous weapon to place in the hands of an enthusiast, be his mission to utterly destroy the Amalekites—that is to say, the alternate-current men—or merely to exalt the virtues of a particularly fanciful form of current wave. The misuses to which statistics might be turned are, indeed, so many that it is fortunate they prove such very dry caviare to the general. Across the Atlantic, it is true, no self-respecting individual is without his string of so-called "useful data"; with us, anyone who gives way without restraint to his fondness for figures is suspect. In moderation, however, and well arranged and well digested, statistics may in many cases be made actually interesting even to the sciolist, and in almost any case they are of sufficient utility to the expert to justify their existence. The tables dealing with the electric supply business of London, which we publish this week, have, we trust, at any rate the merit of usefulness, although as to general interest it may be they scarcely compare with many collections of figures that might be mentioned.

In preparing these tables year after year one fact is persistently borne in upon us, namely, the unreliability of statistics, unless most carefully sifted, as a basis for exact argument. Here we have something less than a dozen concerns, all of which are engaged in the same business, in the same town, and all of which are bound by law to prepare their accounts on the same lines; yet in almost every instance there are differences not sufficient perhaps, if ignored, to in-

validate an argument, but quite enough to make good a charge of inaccuracy, whilst in some instances the differences are by no means trifling. Deductions from statistics have always to be made with discretion; how great that discretion must be in most cases is evident from the openings for mistaken conclusions afforded even by figures so much above the average in clearness and accuracy as those which go to fill the annual returns made to the Board of Trade by statutory electric light undertakings. So far as foot-notes can apply the necessary qualifications to bare figures we have endeavoured to qualify them. Another point in connection with the compilation of these tables is the unaccountable reluctance of one of our largest metropolitan electric supply companies to make public the number of units it is their good fortune to sell every twelvemonth. Technically, we believe, the company in question is quite within its rights in refusing to comply in this respect with the requirements of the Board of Trade model form of accounts. By Section 9 of the Act of 1882 it is undoubtedly laid down that: "The undertakers shall on or before March 25th in every year fill up an annual statement of *accounts* of the undertaking made up to December 31st then next preceding, and such statement shall be in such form and shall contain such particulars and shall be published in such manner as may from time to time be prescribed in that behalf by the Board of Trade." But it is to be observed that this section applies wholly and solely to accounts, and accounts are nothing more than "a registry of *pecuniary* transactions." Hence a company which desires to stand upon its rights may very reasonably object to make public the number of kilowatt-hours it has generated, sold and wasted, as being quite as much outside the radius of the word "accounts" as a statement of the tons of coal or gallons of water used. So long as the Board of Trade confines itself to asking how much money is received by a company in return for the x units received by its customers, so long must its request be complied with in virtue of Section 9. But the moment a company is asked to solve for x, it may politely but firmly decline to do so. Nevertheless, it is not very apparent what harm can accrue from the publication of a figure, which every other similar concern has made public without injury to itself and with considerable advantage to the electric supply industry generally. In a business of a purely mercantile character, in which there is keen competition, the argument against the publication of detailed accounts has some force; in the electric supply business as carried on in the metropolis it has none. On the contrary, the publicity to which every item of capital outlay, every improvement in output, every economy in management, has been exposed from the beginning is largely responsible for that very sound state of the electric supply industry in London of which English electrical engineers are justly proud. Directors and central station engineers are able to discover at a glance, by comparing corresponding items, the weak spot of their particular system. Before an evil can be remedied it must be discovered. Moreover, a spirit of emulation is introduced by the publication of comparative statistics which can have nothing but the best results, since, in view of the disastrous effect of chronic breakdowns, undue economy is not likely to be practised.

Notwithstanding the array of figures in the tables, reference to a few of the more important totals may be permitted here. In the first place, the total capital outlay of the London companies, which amounted in round figures to 8½ millions sterling at the end of 1893, had increased to £8,900,000, *i.e.*, by 11 per cent., at the end of 1894. The total output for the past year was greater than that for 1893 by nearly 39 per cent., the Board of Trade units sold in 1894 aggregating over 13½ millions. This latter figure undoubtedly understates the truth, since the London Electric Supply Corporation has filed no accounts for 1894, and its 1893 figures have, therefore, been repeated, and the output of the Metropolitan Electric Supply Company has been computed on a basis decidedly unfavourable to it, though the only one available to us. Coming to the revenue account, the total income for 1894 amounted, in round figures, to £370,000, an increase of 30 per cent. on the corresponding figure for 1893. The total expenditure amounted to £235,000, an increase of only 22 per cent. on the 1893 total. The average ratio of expenditure to receipts now stands at about 63 per cent. The average "total cost" of a Board of Trade unit has been reduced from about 4¾d. to a fraction over 4d. All these averages would, of course, be considerably improved if the fatal 1893 figures of the unfortunate London Electric Supply Corporation were eliminated. However, notwithstanding their inclusion, it is evident that the business of electric supply is making healthy progress in London.

GAS ENGINE ELECTRIC SUPPLY STATIONS.—I.*

In the early part of the present year a representative of *The Electrician* made a tour of the gas engine electric supply stations of Great Britain and Ireland, for the purpose of making a comparative study of this, relatively speaking, modern form of electric supply works. It is now intended to embody the information thus gathered together in the form of a short series of descriptive and, to some extent perhaps, critical articles. Notwithstanding that we found the state of affairs very far from wearing a rosy hue in more than one station, the general and prominent impression which we received went only to strengthen and deepen our faith in the ultimate success of this type of station. Gas power in electric supply stations has not only proved itself to be an established commercial success, but it has also given good grounds for believing that it can be made increasingly successful. If at the present time gas stations are made to pay—and it will be shown that they are—there are indications of further margins of possible economy which only time and increased experience are required to turn into actual economy. Indeed, the prospect of the gas engine as a motor for the dynamo in supply stations appears to be a very good one, whether viewed from the theoretical, the technical or the commercial standpoint.

Turning now for a moment to take a general glance at the less rosy side of the matter, there may seem to be ground for some discouragement—if not for a reversal of the verdict, for the time being—in some of the vicissitudes of gas-engine stations. Of those which we visited, one was on the eve of quitting its *locale* and removing to a place at a greater distance from human private residence, because it had been voted an intolerable nuisance on account of the malodorous gases which were emitted from it. And another was about to place the entire body of its gas generating and engine plant "on the scrap heap," so to speak, and to substitute steam plant, for reasons which, if not quite so explicit, were at any rate apparently not less convincing to those who had control of the matter. And yet a third station which the writer visited had scarcely got past its embryonic stage, or, to take another simile, had not yet travelled far enough on its path of duty to rub off its scarcely-dried paint, or to blow away the odour of its plentiful varnish. Yet all these matters are mere contingencies, and by no means ought to affect a general conclusion. It is not essential to a gas-engine station that residents in its vicinity shall lose their appetites and suffer unpleasant qualms, nor are those conditions always present which, in one case, have obliged the owners to replace their gas engines by ones driven by steam. Nor is anything

* All rights of reproduction are reserved.

more than time required to turn an embryonic and brand-new station into one ripe with experience, and even the smell of varnish goes off in time. We may say that almost all the evil or negative quantities cancel out, leaving little else than the positive or favourable ones to affect the final result. In fact, it is not the least of the advantages of a comparative study of these stations that we are able to perceive that the defects of each are absent from the others, and to infer that the items of success in each will not be long in aggregating themselves into more than one actual station in the future.

In estimating the suitability of gas power for an electric lighting station, there are two main considerations which it is necessary to make: (1) as to the superiority of gas-engine power over ordinary gas lighting, and (2) as to the superiority of gas power over any other form of motive power for driving dynamos. In any formal treatise it would be requisite that both these points should be fully discussed; but in the present series it is intended to proceed somewhat differently. It will be sufficient if we are able to state just what gas power is found to cost in those actual stations where it is used. The reader will, no doubt, be able to make for himself any comparison he may desire between this cost and that of any other proposed system of lighting.

Gas engines have been used for driving dynamos almost as long as dynamos have been in existence. Most of the early isolated installations of electric-light plant were driven by gas power; and, in fact, much of the experimental and initial experience in electric lighting was obtained with plant of this description. But there is considerable difference between the conditions of working of plant such as this, even in modern times, and those conditions which obtain in a gas-engine installation designed to meet the requirements of public supply. This is true of any kind of engine or motor; it is true of steam plant; but it is more essentially true of the gas engine. What success will be achieved with this engine, and how it will behave, when it is used for lighting a private house with an ample storage plant to cover its multitude of sins, are no guide to the manner in which it will behave, or how successful it will turn out to be, when it has to take its share with several others in the duties of a supply station. To begin with, the same design of engine will not meet the requirements in the two cases; and further, there is hardly one single condition common to them both. That this is so will become more evident when we enter into detailed descriptions of the several stations. If this fact is borne in mind, the reader will the better be able to appreciate the difficulties in which the pioneers of gas-engine stations have at times found themselves, and to understand why it is that, although abundant experience of the gas engine *per se* had been pressed into service, this type of station has had to go through a distinct process of evolution —an evolution which, by-the-bye, is by no means yet completed.

The history of gas engine stations for public electric supply and for electric lighting on a large scale is one of great interest, but we cannot find space in this introduction to notice more than a few incidents. According to Mr. Emerson Dowson, to whose valuable contributions to the literature of gas power we shall make frequent reference, the first important electric supply station worked by gas power was opened at Dessau, in the Duchy of Anhalt, in Germany, in September, 1886. This station was established by the German Imperial Continental Gas Association, in the belief that it would not only promote the use of their gas during the day-time, but also cheapen the production of light. So successful was the initial experiment that the Gas Association has extended the system to other towns in Germany in which it has gasworks. An account of this station appeared in the *Journal of Gas Lighting*, of January 5 and 12, 1892, as a translation from the German of M. W. von Oechelhäuser; and further details are supplied in Mr. Dowson's Paper on "Gas Power for Electric Lighting."* "When the station was opened in 1886," writes Mr. Dowson, "the largest gas engine made gave only 60 (effective) H.P. with two cylinders. They then had two 60 H.P., one 30 H.P., and one 8 H.P. engines, and all the dynamos were driven by belting and countershafts. In 1891 a considerable change was made, as the result of five years' experience, and as larger gas engines were then being constructed, they retained one engine of 60 H.P., with its belting and countershaft, and substituted for the other engines one of 120 H.P. (effective), coupled direct to its dynamo." The success of the latter mode of driving—which is wholly unknown in English gas-power stations—led the Association to decide to adopt it in all their other engines, both at Dessau and in other places. The speed of the 120 H.P. coupled engine and dynamo just referred to is 150 to 160 revolutions per minute, a coal gas consumption of 39 cubic ft. per kilowatt-hour at dynamo terminals being, it is said, obtained at full load. By comparison with this result, it may be remarked that the belted engines at the Dessau station consumed, in the case of the 60 H.P. set, as much as 42 cubic ft. of the same quality of gas per kilowatt-hour; and the loss of power between the engine and the dynamo terminals was 20 per cent., while the loss was only about 10 per cent. in the direct-coupled set. This does not, of course, include the losses in the engine itself.

* *Proc.* Inst. C. E., Vol. CXII.

The following is a summary of the advantages which were found to accrue from the use of gas in the Dessau electric supply station; this summary having been published in May, 1892, after five years' experience, by the German Imperial Continental Gas Association:—

1. Small space required for plant and station.
2. Small consumption of water.
3. No coal or fuel to carry (by hand).
4. No smoke.
5. No risk of explosion.
6. Cheaper than steam engines in respect of (*a*) ground required; (*b*) relative convenience of gas motors as compared with steam in a town, whence greater choice of place within a town and shorter distance to lay cables; (*c*) gas motors above 100 H.P. being cheaper than steam plant.
7. Less loss of electric power, because station is more favourably situated.
8. Less attendance and wages.
9. Exact control over fuel.
10. More regular working and greater security of power to meet unforeseen demands.
11. Cost of fuel can be reckoned at cost of gas supplied—if gas company runs the station.

Although some of the foregoing conclusions are not quite in agreement with English practice at the present time, the summary is interesting as showing the results of prolonged experience on the part of actual gas manufacturers supplying electric power. Doubtless this is a phase of gas-engine station development which, in this country, will before long occupy the serious attention of town gas manufacturers. To be quite exact, we should say that it already has occupied their serious attention; for one of the most interesting of the various schemes for gas stations was advanced by Mr. Denny Lane, the manager of the Cork Gas Company's works, in October, 1891 (see *The Electrician*, Vol. XXVII., p. 629). In another sense, gas manufacturers may be said to be running electric supply stations when, as at Burton, they use steam plant which is fired with the refuse from the gas works; but that is not the sense here intended.

Mr. Denny Lane's proposal may be summarised as follows. The pivot of his scheme is the fact that a given amount of energy can more economically be transmitted a short distance by gas conveyed through pipes than by means of electric feeders. Mr. Lane proposed to replace the "central" electric supply station by ordinary gasworks; and to substitute gas mains for the electric feeders. At the feeding points—the further ends of the gas mains—there were to be gas-engine sub-stations, where gas engines would drive low-pressure dynamos, and where the energy of the gas would be transformed into electric energy. This electric energy would be fed on to the low-pressure network of electric supply mains, just as if it had been brought to the point by a feeder. Coming to Mr. Lane's figures, we find that he calculated that 1 H.P. of gas propelling power will transmit enough gas for 3,000 H.P. over a distance which will cause a loss of gas pressure of 4in. of water. Putting this in another way, it is equivalent to 300 H.P., or 900 cubic ft. of gas per hour, transmitted a distance of one mile in a 6in. main. The cost of such a gas

Digitized by Google

main Mr. Lane estimated at £352 per mile, plus £132 per mile for laying, or a total cost of £486 per mile. The annual interest on this sum he reckoned at 1s. 8d. per horse-power transmitted, and taking gas at 2s. 6d. per 1,000 cubic ft., the 800 H.P. is transmitted a distance of one mile at a cost of 0·1 penny per hour. These figures are applicable only to coal gas or gas of equivalent richness, and they become considerably modified when it is proposed to use diluted water gas, such as that made by the Dowson process.

As yet, British gas companies have not ventured to adopt Mr. Lane's scheme, but an application of the scheme in a modified form occurs at Belfast, where the Corporation electric supply station is run by gas power, the gas being metered into the station from the mains of the Belfast Corporation Gas Works. At Leicester, too, the Midland Railway Company has a gas-engine station for generating electric power for the railway station and yard lights, and although the gas is principally made by Dowson producers on the spot, it is also, to some extent, derived from the town gas mains.

Before concluding these preliminary remarks, we may consider two further matters of importance: (1) The general character of the gaseous fuels used, and (2) the principal arguments of a general nature which have been advanced in favour of and against the use of gas plant in electric supply stations.

Up to the present time only three kinds of gaseous fuels have been employed in the stations with which we are directly concerned, namely, town coal gas, town enriched water gas, and Dowson gas. The name Dowson gas is here applied to all gaseous fuel made by a process resembling that used by Mr. Dowson, whether actually made in Mr. Dowson's apparatus or in modified forms of it.

Table I. shows the composition of a number of samples of town coal gas, and clearly indicates the considerable range over which the composition varies. The average specific volume of coal gas, at atmospheric pressure and ordinary temperatures, is about 30 cubic ft. per pound of gas. One pound weight will develop about 22,000 British thermal units by its complete combustion. The thermal value of one cubic foot is, therefore, about 733 B.T.U. This may be expressed somewhat differently by saying that coal gas consumption at the rate of 1 cubic ft. per hour is equivalent to 0·285 H.P., or 1 H.P. can theoretically be developed by the combustion of 3·51 cubic ft. of gas per hour. These figures will be useful for comparison with the actual results obtained in practice.

Both Dowson gas and town enriched water gas are commercial modifications of a mixture of gases, known as water gas. Pure water gas is a mixture of hydrogen and carbon monoxide in definite proportions, and is generated by the action of steam on incandescent carbon. The chemical action which ensues may be represented by the following equation:—

$$C + H_2O = CO + H_2.$$

Equal volumes of the two gaseous fuels are generated, and the proportions by weight are 93·33 per cent. of carbon monoxide and 6·66 per cent. of hydrogen. The former gas is highly poisonous; hence, from its large percentage in the mixture, it becomes necessary to take great precaution that commercial gases generated on this principle do not escape from the generating plant, the pipes, and the engine. In the commercial water gases, such as Dowson gas, the percentages of carbon monoxide and hydrogen are not so high as in the pure gas; but the proportion of the former is always sufficient to render the mixture poisonous. Town gas is in some places composed of water gas which has been rendered capable of giving a luminous flame by the admixture of oil vapour. Various enriching substances are employed, but principally benzol or light mineral oil distillates. The town gas of Belfast is an enriched water gas of this kind. Dowson gas consists of water gas which has been diluted by certain inert gases during the process of manufacture. It is practically non-luminous, burning with a faint blue or purple flame. It will be more convenient to describe the details of its manufacture when considering the stations where it is used. The composition of this gas varies widely, according to the conditions under which it is manufactured; but Table II. may be considered to represent a good sample. This analysis was made by Dr. C. Monaco, of Turin, and the sample was taken from the gas holder and not directly from the gas generator.

Table II.—*Average Composition of Samples of Dowson Gas taken from a Gas Generating Plant at Canale, Piedmont. Temp., 32°F. Pressure, 14·22lb. per square inch.*—(*Dr. Monaco.*)

—	Percentage volume.	Percentage weight.	Weight in pounds per 1,000 cubic ft. of Dowson gas.

Nitrogen, N …………	46·73	52·13	35·595
Total……………	100·00	100·00	68·281

According to this analysis, average Dowson gas possesses the following properties. The theoretical volume of air required for its complete combustion is equal to the volume of the gas itself; the heat evolved by the combustion of 1lb. of the gas is equal to 2,600 B.T.U.; and the heat evolved by the combustion of 1,000 cubic ft. is equal to about 177,500 B.T.U.

The principal arguments which may be advanced in favour of the use of gas power in electric supply stations are as follows:—Thermodynamically, the gas engine has both a higher range of *possible* efficiency and a higher degree of *realised* efficiency, than any other form of heat engine. The actual thermodynamical efficiency of the modern gas engine is as high as from 15 to 20 per cent.; and a possible efficiency of 80 per cent. is claimed by some writers. Practically, the gas engine offers several advantages, many of which have already been specified; and to the previous list may be added: (1) less cost of fuel, when suitable gaseous fuel is chosen; (2) less waste of fuel in running engines on light loads, because there may be little or no stand-by losses in gas plant; (3) greater promptness in starting and shutting-down the station.

The principal arguments which have been advanced by the various opponents of this type of engine are the following: (1) that the engine is not capable of sufficiently sensitive governing; (2) that it is dirty in working, and takes a great deal of labour in keeping in cleanly order; (3) that the fact of its being an explosion engine renders it unsuited to steady driving; (4) that it cannot be made in sufficiently large units of power for other than very small stations; (5) that it cannot be made economical on small fractions of full load; and (6) that a gas-engine station in a populous district is a noisy and noisome nuisance, anyway. The sequel will show to what extent these objections are invalid.

Paris Congress of Applied Chemistry.—The Organising Committee of the International Congress of Applied Chemistry, to be held in Paris next year, met, says *Nature*, a few days ago to make preliminary arrangements. The Congress will be divided into 10 sections, and electro-chemistry is one of the number.

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(*Continued from page 265.*)

46. Shipboard Galvanometers.—The marine reflecting galvanometer devised by Lord Kelvin years ago still retains its place on board ship as the most reliable for bridge balances and null methods generally. On account of the rolling of the ship the ordinary suspension of the mirror (hung from a fixed point at the top and free below), as in a shore galvanometer, is out of the question; the suspension silk must be fixed top and bottom, so that the axes of the mirror and coils coincide in all deviations of the galvanometer from the vertical. The mirror

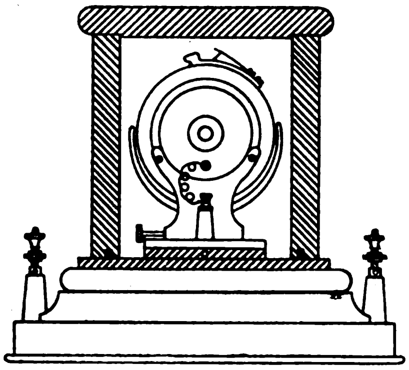

Fig. 129.—Marine Galvanometer.

(with the needles cemented at the back) is suspended on a fine silk fibre mounted in the brass frame shown in Fig. 130. The lower end of the fibre is fixed, and the top end passes out through a central hole in the frame, and is attached to the spring S, which puts a slight tension on the fibre. When the mirror is suspended, the frame is held by the finger and thumb at the projection H, and slipped into place between the two coils as in Fig. 129. The mirror is then central and in the axis of the coils. The instrument is enclosed in a heavy soft iron case (shaded in section lines in the figure) which is a shield against magnetic disturbances set up by the movement of the ship's iron framework when the vessel rolls. A small glass window is

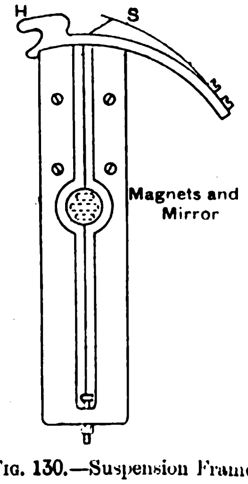

Fig. 130.—Suspension Frame.

provided for the rays of light to pass to and from the mirror. There is a stationary controlling magnet under the lower half of the coils, which keeps the magnets and mirror in the same plane as the coils, independently of the ship's position with respect to the earth's magnetism, and also a convenient screw adjustment (by a pinion and rack rods) of two small controlling magnets, by means of which the spot of light can be brought to zero.

As mentioned above, the instrument is at its best in bridge balances and other tests involving a simple balance to zero. It also does fairly well for false zero work, but it requires practice to read a deflection instantly, as the spot oscillates for some time before coming to rest. This is chiefly due to the very small damping. The magnets at the mirror back are very small, and the resistance of the coils high, so that there is very little induced current due to the motion of the magnets to produce damping. Further, the instrument is quite unsuited for the measurement of momentary currents, such as electrostatic discharges, owing solely to the absence of inertia in the suspended magnets; but such measurements are seldom required on board.

Generally speaking, the conditions of cable testing call for galvanometer suspensions of three distinct types, as follows:

1. The sensitive and light type of suspension, with air damping (for zero balances and deflection readings). Suspension fibre at top only.
2. The heavy or inertia type, with no damping (for momentary currents such as cable or condenser discharges; in this the swing is slow). Suspension fibre at top only.
3. The dead-beat type, with light suspension and plenty of damping (for fault testing.) In this the swing is quick, and it comes to rest immediately. Suspension fibre or wire at top and bottom, generally.

The Thomson reflecting galvanometer, as used on shore, fulfils for all practical purposes the first two conditions, notwithstanding the damping and want of weight for reading discharges. The angular movement is so small for a large deflection of the

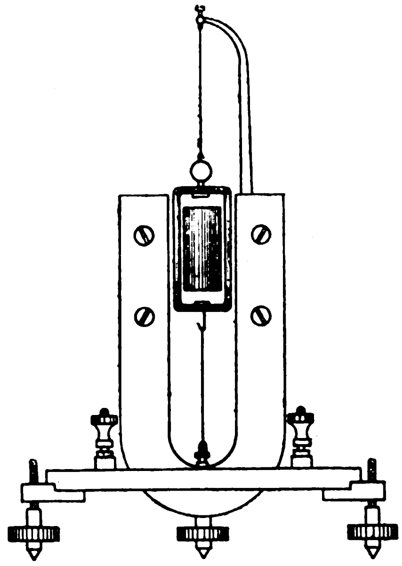

Fig. 131. —Deprez-d'Arsonval Galvanometer.

spot of light that the difference is inappreciably small. In the marine galvanometer, however, the case is different. The lightness of the suspension and fixing of the same top and bottom gives a type of suspension at once very good for the first condition and useless for the second.

It is not absolutely necessary to have a dead-beat galvanometer for fault testing, and the marine galvanometer in practised hands behaves well enough, but it is a great convenience to have a dead-beat one.

Two types of dead-beat galvanometers have been noticed in this work—one damped by air, and another by water. A very good type of dead-beat suspension is in the Deprez-d'Arsonval galvanometer, commonly known as the d'Arsonval. This instrument has a rectangular coil of fine copper wire suspended top and bottom (by thin silver or platinum threads) between the poles of a powerful compound horse-shoe steel magnet (Fig. 131). The tension on the suspension is adjusted at the lower end by the screw, as in Fig. 132, and the suspension wires themselves connect the ends of the coil electrically with the terminals of the instrument. There is also a hollow cylindrical soft-iron core inside the coil, and therefore the coil is in a strong magnetic field. The instrument is on the same principle as the Thomson Syphon Recorder. The current imparts to the coil magnetic poles on the front and back faces, which immediately

* Copyright. All rights reserved.

Digitized by Google

turn towards the opposite poles of the permanent controlling magnet, and therefore the coil turns one way or the other according to the direction of the current put through it. A mirror is fixed to the top of the coil at its centre, by which the deflections are observed in the usual way by a reflected ray of light. The resistance of the coil is generally made small, about 200 to 500 ohms, so that when circuited across the ratio arms of the bridge the damping effect is considerable. The damping in this instrument is entirely by electromagnetic induction, and is most marked when used on a low external resistance and low resistances in the bridge arms. The coil, by virtue of its electro-magnetism and its movement, induces currents in the soft-iron core and magnets; these currents, as is well known by Lenz's law, being in a direction to oppose the motion of the coil, and thus checking or damping its travel. A further damping effect is obtained by winding the coil on a bobbin of thin metal sheet. The instrument is consequently very dead beat, coming instantly to rest after deflection, and is very useful in false zero work.

Some experiments with a suspended coil mirror galvanometer were carried out by Mr. E. Raymond Barker in the year 1887 (*The Electrician*, October 17, 1890) at the Madeira station of the Brazilian Submarine Telegraph Company, with the view of ascertaining its adaptability for signalling purposes under certain conditions. The bifilar suspension with weights, as in the Thomson Syphon Recorder, was used, and it was found that

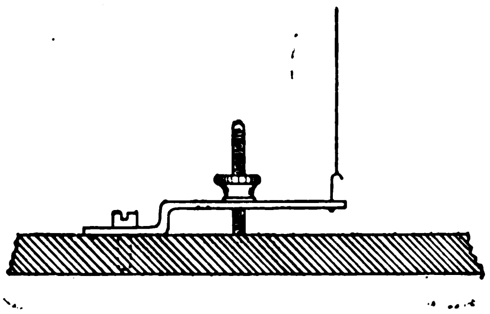

FIG. 132.—Details of Suspension.

the strong directive force of this suspension prevented interference by currents of a vibratory nature, while it was even more sensitive than the ordinary mirror instrument to signals. The signals also were equally good through cables differing in length as much as from 1 to 2,000 nautical miles.

47. Capacity Tests.—It has long been observed that after submersion the capacity of a cable, when tested by the ordinary methods, appears higher than that obtained by measurements during manufacture, and a considerable amount of attention has been devoted to this question to find a correction generally applicable. The factory tests are made on short drum lengths of core in tank each of about two knots, and the sum of the capacities of the several lengths of core composing the finished cable is taken to represent its true capacity. The comparison of the capacity of a piece of cable core with that of a condenser of known capacity is the first step, and, accepting the capacity of the condenser as the true standard, it is evident that the capacity of the cable can most truly be measured by comparison with that of the condenser when the piece of cable under measurement differs least in its electrical properties from those of the condenser, and this condition we have in the short length of core. In the first place, there is no retardation of charge or discharge, these being instantaneous as in the condenser, and in the next place, the insulation resistance more closely approximates to that of the condenser. The error due to difference in the rate of absorption of charge, owing to the different nature of the dielectrics, can be corrected by Dr. Muirhead's method.

Besides measuring the capacity of the drum lengths, the capacities of the completed sections of sheathed cable are tested in the factory before shipment. These sections differ according to the type of cable, and may vary from 200 to 250 knots of deep-sea cable down to 50 or 100 knots of intermediate, or 1 to 10 knots of shore-end. The apparent capacity of these sections is found to be greater than the sum of the capacities of the core lengths composing them, and the final measurement of the whole cable when laid often shews a different capacity per knot depending on the retardation as affected by length of cable and insulation resistance as affected by bottom temperatures. Again, the apparent capacity of a submerged cable increases as its insulation resistance falls, so that it is most important to be able to apply a correction in localising a sealed rupture of the conductor when the insulation is reduced by one or more low places. The time of charge also affects the apparent capacity: the longer the time of charge the greater the apparent capacity. This, however, is within pretty well defined limits, the minimum time taken for a cable of given length to receive a charge at uniform potential throughout being known to a sufficiently close degree.

In the well-known work entitled "Electricity and Magnetism" of the late Prof. Fleeming Jenkin (page 331 of fifth edition), a formula is given by which the time taken in any given cable for the full charge or any given fraction thereof to reach the distant end may be calculated. The following constant is first worked out for any cable under consideration:—

$$F R L^2 \times \frac{233 \cdot 2}{10^{10}},$$

where F is the capacity per knot in microfarads,
R is the conductor resistance per knot in ohms,
L is the length of cable in knots.

The time in seconds in which any percentage of the charge will reach the distant end is then found by multiplying the above constant by a certain number corresponding to each percentage. Thus, multiplying the constant by 6 we have the time in which half the charge will reach the other end; multiplying the constant by 20 gives the time for 98 per cent., or multiplying by 25 gives the time for $99\frac{1}{3}$ per cent. of the charge to reach the distant end of the cable. To reach 100 per cent. of course takes a theoretically indefinite time, but it will be evident that 98 or 99 per cent. of the charge may be considered as the whole charge. For instance, taking the French Atlantic cable, in which the dimensions are length 2,584 knots, capacity 0·43 microfarad per knot, and resistance 2·93 ohms per knot, the above constant works out to 0·196, and this multiplied by 20 gives nearly 4 seconds as the time taken for 98 per cent. of the charge to reach the distant end. Similarly, multiplying by 6 gives nearly $1\frac{1}{5}$ seconds as the time in which the charge will attain half its full potential at the other end.

The most reliable tests for capacity are those devised by Sir W. Thomson (Lord Kelvin), namely, the "mixed-charge" method and the "bridge" method. To the latter a correction for rate of absorption has been devised by Dr. Alexander Muirhead. The bridge method is sometimes alluded to as that in which the cable and condenser are "in cascade." Kempe describes it under the title of Gott's test, by which it is usually known. Mr. Gott independently devised the method, but it was first published by Sir William Thomson in the *Journal* of the Society of Telegraph Engineers, Vol. I, pp. 397 and 398. The tests differ in the position of the earth connections, and in the manner of observing balance, but in other respects they are identical—that is, the condenser and cable under comparison are charged with equal quantities in each method, and at different potentials measurable on the slides or bridge; and the formulæ are the same.

(To be continued.)

A Method of Determining Furnace Temperature.—In a recent communication to the Académie des Sciences, M. Berthelot suggests a method of determining the temperature of a furnace, which is based on the fact that the refractive index of a gas varies with its density. Two tubes filled with the same gas are taken, and a spectrum refracted through each, the two spectra being observed together. If then one is raised to a high temperature, and its contents allowed to expand, so as to maintain the pressure inside constant, it will be necessary to reduce the pressure in the second tube in order to re-establish coincidence between the two spectra. Preliminary experiments in the laboratory have shown the method to be capable of giving very accurate results.

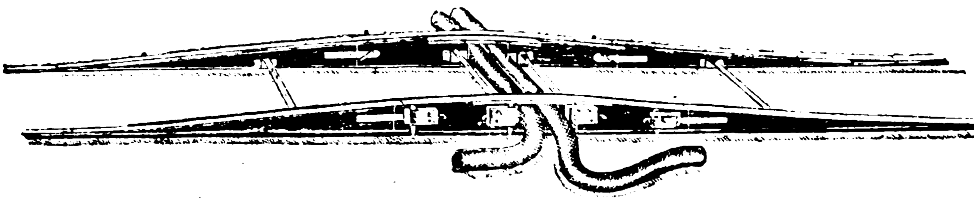
A PORTABLE HOSE BRIDGE.

In a recent issue the *Street Railway Gazette* describes a fire hose crossing designed to prevent the delays that are caused in the United States by fire hose stretched across the street railway tracks.



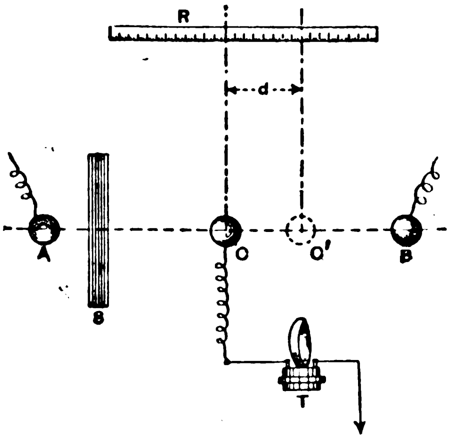
The hose bridge, which is shown in the accompanying illustration, is 16ft. in length, each side being composed of three sections which can be quickly and rigidly connected by a clasp. Braces keep the sides firmly in place, while ratchet spikes, held firmly by springs, hold the parts to the ground and rail. The parts are all made of the best and heaviest materials, and are intended to carry the heaviest motor cars and trailers. The bridges will fit any kind of rail, and are made for any gauge. The bridges can, it is asserted, be placed in position by one man within three minutes. Two lines of the largest fire hose made can be used through the bridge. These bridges are in use in Detroit and other American cities.

A NEW METHOD OF MEASURING SPECIFIC INDUCTIVE CAPACITY.*

BY ALBERT NODON.

The method I am about to describe is the result of some researches which I undertook in May, 1887, in the physical research laboratory, in collaboration with M. Pellat, professor at the Faculty of Science of Paris. These researches related to the laws governing the deflection of the inductive flux in its passage through dielectrics.

If we take two metallic spheres of small capacity and place them in connection with a source of high pressure electricity rapidly varying, such as an induction coil, and if we place between these two electrified spheres a third, also of small capacity, connected to a telephone, one pole of which is to earth, it will be found that there is a well-defined point between the inducing spheres at which the ear ceases to hear any noise in the telephone. The exploring sphere is then in a region where equal and opposite potentials are produced, and their effect is therefore neutralised. Things being in this state of electrical equilibrium, if a parallelipiped be introduced between one of the inducing spheres and the exploring



sphere it will be found that the state of equilibrium is immediately upset. On the ear being applied to the telephone the characteristic rumbling is immediately heard. To restore silence it is only necessary to move the exploring sphere in one direction or the other. The amount of the displacement which is necessary enables one accurately to determine by comparison the specific inductive capacity of the substance which has been interposed.

In the accompanying figure A and B are two copper spheres about 10 millimetres in diameter connected with an induction coil; C is the movable exploring sphere, the motion of which is measured by means of the graduated scale R; T is a telephone, one of the poles of which is connected to the exploring sphere and the other pole of which is to earth. S is a parallelipiped consisting of a dielectric of known thickness, the specific inductive capacity of which it is required to know. It is absolutely essential that the apparatus should remain absolutely the same during an experiment; the conducting wire should also be arranged in a fixed manner and the telephone should be placed several metres away from the apparatus on a fixed stand.

The experiment is conducted as follows:—The equilibrium position of the sphere is first determined. A standard dielectric is then placed between the two spheres A and C, its specific inductive capacity and thickness being known. Paraffin is chosen as the standard dielectric, as it is one of the substances which best fulfil the conditions of the experiment. The interposition of this parallelipiped of paraffin upsets the electrical equilibrium of the inductive system formed by the three spheres A, C, B. The telephone immediately rumbles, and silence is not restored until the sphere C is moved to the position of C'; the distance between the two points C and C' is proportional to the inductive capacity of the paraffin parallelipiped, and will serve as a basis for subsequent measurements. If, now, the parallelipiped S is replaced by another parallelipiped of some other substance, such as sulphur, a new length d' will be obtained before there is silence in the telephone. If we denote the specific inductive capacity of the paraffin by I, the first measurement by d, and the second measurement by d', then the equation to the specific inductive capacity of the second substance, silver, will be $I' = I \times \frac{d}{d'}$.

To measure by this means the specific inductive capacity of dielectric liquids, it is only necessary to place the substance in troughs having parallel faces, and consisting themselves of dielectric material, the specific inductive capacity of which has been determined beforehand. The difference between the values of the specific inductive capacity of the trough when full and when empty will give the required result. In the same way the specific inductive capacity of gases may be determined.

The method which I have just described enables one to obtain in an equal, simple and accurate manner the specific inductive capacity of solids, liquids and gases, and I think it should be of some use in electrical laboratories, in which the determination of specific inductive capacities according to existing methods is long and difficult.

* From *L'Electricien*.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *June 14, 1895.*

Electricity on the New York Elevated Roads.—Periodically for several years the newspapers have announced that the Manhattan Elevated Railway had decided to displace steam by electricity for motive power, and each announcement has been followed by an unqualified denial by that Company. To-day, however, the newspapers contain an interview with the chief engineer of the New York elevated system, in which he states that the contract for an electrical equipment, involving an expenditure of from $6,000,000 to $8,000,000, has been given to the Westinghouse Company. The newspaper account further says that the driving motors will be of 200 H.P. and the trains lighted and heated by electricity. But a short time ago the chief engineer, in denying a rumour of a contract for

Digitized by Google

an electrical equipment, referred to the great expense of a change from steam to electricity, which, he said, would involve an expense of $3,000,000; in view of this, the figures quoted above seem rather wide of the mark.

The General Meeting of the American Institute of Electrical Engineers.—The Niagara meeting of the American Institute of Electrical Engineers promises to be one of unusual interest from an engineering standpoint, not only on account of the character of some of the Papers to be read, but from the fact that during the meeting the Niagara plant will be put in commercial operation. Among the Papers is one by the newly elected president, Dr. Louis Duncan, on the electrical system adopted by the Baltimore and Ohio Railroad to transfer its trains through the City of Baltimore. The lines of this Company pass under the city through tunnels, and hereafter cars are to be transferred by electric locomotives, one of which has been completed. Mr. Chas. P. Steinmetz will answer some of the criticisms to which the monocyclic system and its definition has been recently subjected. Mr. W. L. Emmett, an engineer of the General Electric Company, will describe the electrical features of the works of the Pittsburgh Aluminium Reduction Company, and Mr. L. B. Stillwell, of the Westinghouse Company, will read a Paper on the Niagara power plant. Among other Papers will be one describing the 10,000 volt transmission plant at Pomona, Cal., which has now been in successful operation for several years, and one by Prof. Elihu Thomson on the compounding of dynamos by armature reaction.

New Electrical Journals.—During the past week two new electrical papers have been announced, and, strangely enough, they have the same name—*The Electrical Journal.* One of these will be printed at San Francisco, Cal., and edited by Mr. Geo. P. Low, formerly a daily journalist and more recently an underwriters' inspector. The other has been projected by Mr. J. P. Barrett, City Electrician of Chicago, and will be edited by Mr. J. Allan Hornsby. The former will be issued monthly and the other semi-monthly. It appears that both will be published in the interest of students and others little advanced in electrical knowledge.

CORRESPONDENCE.

MAGNETIC SYMBOLS AND TERMS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: We notice in the editorial columns of your issue of May 31st some criticisms on our Paper entitled "A Contribution to the Theory of Demagnetisation," published in the same issue, to which we beg to take exception.

We object to the inference to be derived from your statement:—

"Every individual is, of course, entitled to have his own opinion as to the relative merits of 'block' and 'black' letters; but the use of 'block' letters having become well established in this country, where modern Magnetism took its growth, we may be pardoned for refusing to countenance any further this anarchic tendency of every new writer on magnetic subjects to employ whatever symbols and terms seem good in his own eyes."

So far as relates to the symbols we employ, we desire to point out that we have not selected these, but that they were recommended by the Committee on "Notation and Nomenclature," appointed by the International Electrical Congress of Chicago, and printed by the Congress in its *Proceedings* as the recommendation of that Committee. This notation has since come into extensive use in the United States and in France.

Concerning the use of the word "gauss," as the name of the C.G.S. unit of intensity, which is already extensively used in the United States, we beg to point out that if the term were more generally used, it would render impossible such misconception as it appears to us your editorial article contains in the passage:—

"The authors employ it for both the unit of H and the unit of B. We venture to regard these two quantities as being as distinct from one another as amperes are from volts."

The volt and the ampere are, of course, essentially different physical quantities, having the respective conventional dimensional formulas $L^{\frac{3}{2}} M^{\frac{1}{2}} T^{-2}$ and $L^{\frac{1}{2}} M^{\frac{1}{2}} T^{-1}$, and are, therefore, properly designated by different names. The unit of magnetising force (H), and of magnetic flux intensity (B), are essentially the same physical quantity, having the same conventional dimensional formula $L^{-\frac{1}{2}} M^{\frac{1}{2}} T^{-1}$, and are, therefore, properly designated by the same name. They are each the unit intensity of magnetic flux, and the fact that a magnetic intensity which we arbitrarily symbolise by H, when acting upon iron, aligns the molecular M.M.F.'s in such a manner that the iron introduces a new magnetic intensity (B – H), does not produce any difference between the nature of B, the resultant, and of H, the prime, intensity.

We fail to understand why you should suppose that H is less readily measurable than B. The earth's magnetic force H is measured in many parts of the world. In every case the removal of iron from an electro-magnetic circuit leaves a flux density H or "magnetising force" which is just as readily measured as B, except in regard to magnitude.

If the definite name "gauss" be employed instead of the indefinite "C.G.S.," such confusion between the natures of the fundamental magnetic quantities as that into which it appears to us that you have fallen, would, we believe, be prevented; for the use of the term could not fail to impress the fact that magnetising force H, field intensity H, and magnetic induction B, are all the same physical quantity, differing only in direction and magnitude, from whatever source they may be derived.—Yours, &c., Houston and Kennelly.

Philadelphia, June 10, 1895.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Your editorial remarks in the issue of May 31st on the new names for magnetic units are very much to the point.

When the names "gauss," "weber," &c., were proposed in the American Institute of Electrical Engineers, one of the chief arguments of their advocates was that the ordinary mind (especially in callow youth, when most studying is done) is greatly assisted by "concrete" names for the "abstract" ideas with which it has to deal, and that the adoption of the proposed names would tend to promote accuracy and precision of thought and to diminish error.

Some of us suggested at the time that people perversely insist upon making mistakes with units which already possess "concrete" names. For instance, the expression "watts per second" is not uncommon, and was once used by a college professor, so I am informed.

Arguments of this kind, however, were considered frivolous by the Committee on Units and Standards, and in consequence the Institute provisionally adopted the names.

As a crucial test of the utility of these "concrete" names in suppressing all looseness and vagueness of thought, and in developing and bringing to the front clear-cut and accurate ideas, nothing can serve better than the use of the name "gauss" by the Chairman of the Committee on Units and Standards, which you criticise adversely.

Messrs. Houston and Kennelly, however, are not the only ones to use the name "gauss" for both magnetic force and magnetic induction. The table published in the *Electrical World* of August 25, 1894, corrected by M. Hospitalier, and afterwards issued on separate cards, gives the name "gauss" three times,—once for magnetic induction, once for magnetic field intensity, and once for magnetising force. The second and third of these quantities are related in a manner somewhat similar to the quantities electromotive force and difference of potential, both of which are measured in volts. The first, however, is a different quantity, as your editorial truly remarks, and as the advocates of this use of the name "gauss" understand. The position of the last-named gentlemen is, so far as I have inquired, that it is mere purism to make any radical distinction between magnetic induction and magnetic force, and although it may be well enough as a philosophical exercise to differentiate them, in practical work it is too much in the nature of hair-splitting. If this be truly hair-splitting, I remain, yours hair-splittingly,

June 14, 1895. Townsend Wolcott.

WAVE FORM SYNTHESIS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The interesting Paper by Messrs. Barr, Beeton and Taylor, begun in *The Electrician* of June 21st, has a special attraction for me, as for some time past I have been occupied with investigations on similar lines. In the spring of this year a report was sent in by me to the City of London Electric Lighting Company, describing the investigations made to determine the various losses in transformers of different types when worked on alternators of different kinds. As this report is no longer my property, I cannot communicate, without permission, the details of the experiments and the results obtained; but there will be no objection to my saying that, by the use of the curve tracer described by me in *The Electrician* some months ago, a very full examination was made of the losses of transformers two kinds on different alternators and on the same alternator with different loads. Generally speaking, it was found that the iron-core loss in any transformer was greatest on that alternator the electromotive force curve of which most closely approximated to a sine curve. Differences to the extent of 10 per cent. and 15 per cent. in the iron-core losses were found when the same transformer was tested off alternators giving electromotive force curves of different kinds. It was also found that the form of the curve of the magnetising current of the transformer, as well as the power factor, was altered by any change in the electromotive force curve.

In these experiments we had not at our disposal the means of altering the form of the electromotive force curve at pleasure. It is obvious that this, however, could be easily achieved by means of a special alternator. It is easy to show from considerations of symmetry that in a periodic curve, symmetrical with regard to the time axis, only the odd harmonic terms can be present, and that for the majority of curves likely to be met with in practice a synthesis can be effected by taking the first three odd terms of the Fourier series.

We have at University College two alternators, the shafts of which are connected, but in which the armature bobbins can be set in any relative position. In order to be able to synthesize most practical forms of curve, it would be necessary to have fixed on the same shaft three alternator armatures giving frequencies in the ratio 1, 3, 5, when the shaft was rotating at one definite speed. This could be achieved by making three armatures having respectively 8, 24 and 40 bobbins. These armatures must be capable of being set in any relative difference of phase, and it would be very easy with a compound alternator of this kind to build up electromotive force curves formed of simple periodic curves with wave lengths in the ratio 1, 3, 5, and having the requisite relative amplitudes.

I entirely agree with your "Editorial Note" in emphasising the practical importance of studying the effect of the form of the primary electromotive force curve on the iron-core losses in transformers, and on the power taken up in alternating-current arcs. This has by no means the mere abstract interest which many have supposed, but has a very practical aspect in connection with alternate-current working. The last word has not yet been said upon the subject of alternating transformers. We have got beyond the stage of providing them with what was once wittily called "ready-made suits of mathematical clothing," and we are now happily in the condition in which current curves of different kinds can be "made to order," and the problem before us is how to make to order in the most economical shape.—Yours, &c., J. A. FLEMING.

RE MR. HOWELL'S PAPER READ BEFORE THE NORTHERN SOCIETY OF ELECTRICAL ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The report giving the substance of my remarks at the recent meeting of the Northern Society of Electrical Engineers has been condensed by the omission of so many important passages that I was hardly able to recognise parts of it. It puts words into my mouth regarding alternating currents which, when read without the other remarks which preceded and followed them, convey a totally false impression. I was at considerable pains to explain that the outcome of the long conflict which has raged between the advocates of continuous and alternating systems of supply has been to show that, however well suited alternating currents, whether monophase or polyphase, may be for power transmission, or even for transmitting the energy for lighting purposes up to distribution centres, they are not well suited for employment in the distribution network, *i.e.*, from these distribution centres up to the consumers' lamps. That this was on account of those very peculiarities inherent in alternating or pulsating currents which on account of the interesting problems involved, so endear them to the minds of professors and students, but which introduced practical difficulties in giving a perfectly regular and steady light free from pulsations.

I pointed out that the most successful way of dealing with these difficulties was to confine the alternating system to the transmission of energy up to the distribution points, to interpose the accumulators at this point, and consequently to use nothing but continuous currents in the network, and I pointed out that the very latest and best Continental practice pointed in this direction.

All this matter, which was certainly given by me at as great a length as I have here written it, has been condensed by the report into five lines, in which I am made to say that I am strongly an anti-alternator man, and that alternating currents were no doubt a splendid thing in their way for professors and school boys, but nasty things to deal with in central stations.

I need hardly point out that such are not my opinions, and that I believe that alternating currents are playing and will play an important part in the electrical industry, and the brief summary of my opinions given in your "Notes" is both unfair to me and misleading to your readers.

Trusting, therefore, that you will allow this letter to appear as a correction,—I am, yours faithfully, R. E. CROMPTON.

London, June 26, 1895.

[We find that the portions of Mr. Crompton's speech relating to alternate currents were inserted by us just as they were received from the Northern Society of Electrical Engineers.—ED. *E.*]

LEGAL INTELLIGENCE.

Sandon v. The Chelsea Electricity Supply Company (Limited) and Fowler v. the Same.

These cases came before Mr. Justice North in the Chancery Division, on Friday, last week, and were brought against the defendant company to restrain an alleged nuisance by means of vibration and noise. By arrangement, the cases were treated as the trials of the actions, the defendants submitting to perpetual injunctions in both cases.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

SPECIAL NOTICE.—The 1895 (thirteenth) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. In addition to the old well-known features of the book, which are brought up to date, a quantity of new and useful matter has been added, rendering the book more than ever indispensable to the Electrical, Engineering, and Allied Trades. Price, 7s. 6d., post free 8s. 3d., abroad 9s.

The following New Books and Editions of "THE ELECTRICIAN" SERIES *can be obtained of the Booksellers or direct from the Publishing Offices:—*

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

TENDERS INVITED.—The Electric Lighting Committee of the Corporation of St. Helens (Lancs.) invite tenders for the supply and erection of boiler and engine-house plant, switchboard and instruments, underground work (including cables, boxes, culverts, &c.), transformers and fittings, meters, and overhead crane for their electric lighting station. Tenders are to be sent in to Mr. W. J. Jeeves, Town Clerk, Town Hall, St. Helens, by Tuesday next, July 2nd.

——— The Town Council of the Borough of Richmond, Surrey, require tenders for an extension of the fire call system within the borough, the extension to consist of three call points. Specifications, &c., can be obtained of Messrs. Urquhart and Small, 17, Victoria-street, Westminster, S.W. Tenders must be sent in to Mr. Frederick B. Senior, town clerk, Town Hall, Richmond, Surrey, by 2 o'clock on Monday, July 8th next. Our advertisement columns contain some further particulars.

——— The Directors of the Manchester Ship Canal Company invite tenders for the necessary work for the permanent electric lighting of the Manchester and Salford Docks, including the supplying of alternators and dynamos, arc and incandescent lamps, cable, wires, &c. Particulars may be obtained at the engineer's office, 41, Spring-gardens, Manchester, and tenders, addressed to the secretary (Mr. A. H. Whitworth) must be in by July 10th. Some additional information is given in our advertisement columns.

——— The Visitors' Committee of the Bristol Lunatic Asylum, Fishponds, Bristol, require tenders for supplying and fixing wires, lamps, &c., for lighting the Asylum by electricity. Particulars may be obtained from Mr. R. Withycombe, clerk of works, and tenders must be in by July 15th. Some further particulars appear in our advertisement columns.

——— The Corporation of Portsmouth invite tenders for the supply and erection of conduits and india-rubber covered electric mains, and for the supply and erection of "compound" covered high-tension electric mains. Some information is given in our advertisement columns. Copies of the specification may be obtained from Mr. Alexandar Hellard, Town Clerk, Town Hall, Portsmouth; and any further information required from the engineers, Messrs. Kincaid, Waller and Manville, 29, Great George-street, London, S.W. Tenders must be sent in to Mr. Hellard by 6 p.m. on July 10th.

——— The Urban District Council of Clevedon require tenders for the public lighting of their district. Tenders are to be for one, two, or three years, and must be sent in to Mr. H. C. Fry, Clerk of the Council, Clevedon, by Monday next, July 1st.

——— The Urban District Council of Wellington (Salop) invite tenders for lighting the district by electricity or gas. Some particulars will be found in our advertisement columns, and all further information can be obtained from the surveyor, Mr. G. J. Monson, 45, Walker-street, Wellington. The tenders have to be sent in before noon on Monday, July 15th.

——— Tenders are invited until August 11th by the Municipal Authorities of Ille-sur-Tet (Pyrénees Orientales), France, for the concession for the electric lighting of the town. Tenders to the Mairie.

——— The Dewsbury Pioneers' Industrial Co-operative Society require tenders for wiring their premises. Tenders must be sent in to Mr. J. B. Mitchell, borough electrical engineer, Bradford-road, Dewsbury, by July 8th.

TENDERS ACCEPTED.—In our issue of June 14th we gave particulars of the acceptance by the Chester City Council of the tender of Thomas Parker (Limited) for the supply of plant and apparatus for the electric lighting of that city. The following is the complete list of tenders:—

Continuous-current Supply	
Thomas Parker (Limited) (accepted)	£14,200
Electric Construction Company	14,847
Alternate-current Supply.	
Brush Company (street lighting not included)	8,922
Electric Construction Company	11,755
Manchester Edison-Swan Company	12,446
Siemens Bros. and Co.	14,800
J. Fowler and Co. (Leeds)	14,893

——— On May 31st it was announced in this journal that the Worcester Corporation had, against the recommendation of a Sub-Committee appointed to consider the subject, decided to accept the tender of a local firm (the New British Installation Contractors, Limited) for the wiring and fitting up for the electric light of the Victoria Institute for the sum of £849. It has now, we learn, been finally decided to accept the offer of Messrs. Graham and Biddle, London, for £768, in accordance with the Sub-Committee's original proposal.

——— The Brighton Town Council have decided to accept the tender of Messrs. Mackenzie Bros., Edinburgh, for the supply of 45 cast-iron upright posts with bracketed canopies, for supporting the arc lamps, for £1,530.

TENDERS ACCEPTED.—The Manchester City Council have accepted the following tenders for plant and apparatus for electric lighting extensions:—

B. Goodfellow, compound condensing engines	£12,440
Electric Construction Company (Limited), dynamos	7,381
Heaton and Son, Lancashire boilers	5,371

——— The tender of Messrs. Clay Bros. has been accepted for the electric lighting of the County Brewery, Cardiff, for £1,337. 17s. Eleven tenders, varying in amount from £1,245 to £1,705, were received.

——— The Bedford Urban Sanitary Authority have accepted the tender of Messrs. Johnson and Phillips for the supply of two transformers and accessories for the sum of £150.

SALE BY AUCTION.—Mr. Wooller Jennings has been instructed by Mr. James Duff, the Receiver and Manager of Andrews and Preece (Limited), to sell by auction, at the Borough Mills, Manchester-road, Bradford, on Wednesday and Thursday next, July 3rd and 4th, at 11 o'clock each day, the whole of the valuable plant of engineers' tools and effects, stock-in trade, &c. Detailed catalogues can be obtained from Mr. Jennings, 66, Thornton-road, Bradford.

BUSINESS FOR SALE.—As will be seen from our advertisement columns, Mr. J. M. Macleod (liquidator under the sequestration of the estate of Mr. J. Scott, trading as D. and G. Graham) has for sale the business of electrical engineers, bell-hangers, &c., hitherto carried on by Mr. Scott, at 134 to 140, Douglas-street, and of wholesale and furnishing ironmongers at 201, Byars-road, Glasgow, together with the stock in trade, plant, machinery, and book debts. The business has been established over 50 years. The stock, plant and machinery may be seen on application to Mr. J. Macleod, 101, St. Vincent-street, Glasgow, who will give facilities for inspecting the works.

WORKS FOR SALE.—There is for sale by private contract, or to be let, the extensive range of buildings known as the Great Bridge Engineering Works, West Bromwich, of which particulars will be found in our advertisement columns. It will be seen that the property contains no less than 8,963 square yards, and abuts on the Birmingham Canal. All further particulars can be obtained of Messrs. Joseph Cooksey and Son, Surveyors, of Lombard-street West, West Bromwich, or of Messrs. Edwards, Son, and Bigwood, Colmore-row, Birmingham.

APPOINTMENT VACANT.—The Governors of the Northern Polytechnic invite applications for the post of principal. After the 25th March next the stipend will be at the rate of £500 per annum, and from September 29th next to March 25th at the rate of £300 per annum. Some further particulars will be found in our advertisement columns, and applications must be sent in to Mr. E. Griffiths, secretary, St. Mary's Vestry Hall, Islington, N., before July 15th, on forms which, together with all further information, can be obtained at the Vestry Hall.

LIQUIDATIONS.—On the 14th inst. it was resolved that the Archer Pipe Company (Limited) be voluntarily wound up. Messrs. John Cocks and Robert Ewing were appointed liquidators.

——— At a meeting on the 5th inst. it was decided to wind up the Telpher Cable and Cliffe Railway Syndicate (Limited) voluntarily, and Mr. J. W. H. Byrne, 81, Gracechurch-street, London, E.C., was appointed liquidator.

COMMERCIAL CABLE COMPANY.—We have received from the Commercial Company four well-illustrated, well-written pamphlets, entitled respectively "How Atlantic Cables are Made," "How Atlantic Cables are Laid," "How Messages are Flashed under the Atlantic Ocean," and "How Atlantic Cables are Repaired." It is a good policy on the part of the Commercial Company to endeavour to interest the public in its doings.

AGENCY.—Messrs. Francis and Spilsbury have been appointed sole agents for the sale of Messrs. J. H. Tucker and Co.'s "crank" switches in Ireland and the east, south and west of England. Mr. Baker continues to represent Messrs. Tucker and Co. in London.

PUSHES.—Messrs. G. Wingrove and Son send an illustrated sheet of Dale's bayonet-joint electric bell push, of which they are the sole manufacturers. This push is usually constructed without a screw, threads being entirely done away with. It is stated to have been highly approved by practical electricians, and is made in four patterns, all of which can be made with screws if preferred (10 threads to the inch).

PETROLEUM GAS APPARATUS.—Messrs. Moeller and Condrup, of London, send us two of their latest sheets of Swedish petroleum gas apparatus. The illustrations include the "Ætna" and "Vesuvius" brazing lamps, "Hekla" portable furnace, and the "Primus" and "Ultraprimus" petroleum lamp stoves. This apparatus burns paraffin oil without wick, and is claimed to be free from smell, soot, or smoke. The "Ætna" lamp, which is recommended for use by electricians, is so constructed that the gas cannot get into the oil tank, and pumping is required only occasionally after

Digitized by Google

the lamp is once started. The lamps are made in sizes varying from two pints to half-a-pint.

THE "SWEET" AUTOMATIC LAMP SWITCH.—Messrs. J. B. Stone and Co., who are the sole London agents for this switch, inform us that they are now in a position to execute orders.

WRIGHT'S PATENT HEATER CONDENSER COMPANY'S PROCESS.—We have received a handy brochure, descriptive of Wright's Heater Condenser Process for softening and purifying water for boiler feed and other uses. The apparatus is made in a variety of forms and sizes, suitable for the various operations in which water softening is necessary. The cost of working such a plant will, of course, depend on the degrees of hardness and impurity of the water treated; but we learn that the average cost is not more than about 1d. per 1,000 gallons.

PRICE LIST.—We have received a four-page price list of the "Interior Conduit" system recently introduced into this country by the General Electric Company.

CATALOGUE.—Mr. R. W. Blackwell sends us a copy of his latest (No. 4) Catalogue, which contains illustrated particulars of a variety of engineering and electrical plant and apparatus, for which Mr. Blackwell is representative in this country. The pamphlet contains an introductory Paper, entitled "How to prevent Electrolysis and make complete Metallic Circuit for an Electric Railway."

ALSAGER (STOKE-ON-TRENT).—The District Council have decided to engage Mr. G. R. Peers, of Bolton-le-Moors, to prepare estimates of the cost of lighting the district by electricity.

BRISTOL.—The Electric Lighting Committee of the Corporation have been successful in an appeal against the rating of the electric lighting works. The assessment was at the rate of £3,000 gross and £1,850 net; and the result of the appeal was that this latter sum has been reduced to £1,500. In the course of the inquiry Mr. Wise, on behalf of the appellants, stated that the figures upon which they based their appeal showed that the number of private lamps fixed on December 31st was 15,000, and they estimated for an increase of about 2,300 for the current year. They obtained an average revenue of 6s. 11½d. per lamp, with discounts varying from 5 to 20 per cent., bringing the net revenue from private lighting to about £5,880. There were 90 public lamps bringing in a net revenue of £3,008, or a total of £8,888 altogether. The cost of production came out at £5,808, and, after further deductions for various items in the accounts, the net annual value of the whole undertaking was £1,545. Notwithstanding considerable opposition, the appeal was, as stated above, successful.

BURNLEY.—Mr. J. B. Clerke last week held a Local Government Board inquiry into the application of the Town Council for power to borrow £50,663 for various improvements, including £1,000 for wiring and fitting up the Town Hall for the electric light, and £5,500 for additional plant, mains, &c., for electric lighting extensions.

CARDIFF.—An application has been made to the Local Government Board for powers to borrow £5,385 to carry out extensions of the electric lighting mains.

CHURCH LIGHTING.—The Deacons' Court of Sandgate Free Church, Ayr, have unanimously agreed to light the church electrically.

COMMISSION OF SEWERS (LONDON, E.C.).—At the meeting of the Commissioners on Tuesday last, the Streets Committee presented a report on the lighting of the minor streets in the City by electricity. They also submitted a report from the electrical inspector thereupon, and recommended that certain experiments therein suggested be made, the City of London Company charging only the actual cost to them of the work, estimated at about £386. This recommendation was approved.

CROYDON.—Major-Gen. C. Phipps Carey held a Local Government inquiry on Wednesday last into the application of the County Council for sanction to borrow £27,000 for electric lighting purposes. Mr. Alderman Miller, J.P., the Chairman of the Electric Lighting Sub-Committee, stated that, from personal inquiries, he found the electric light was much desired in the borough. The Corporation were erecting a new town hall and other public buildings and would be large consumers of current. The inspector said he thought the Local Government Board would require more details, and pointed out that no plans of the proposed buildings had been put in. The Town Clerk said Prof. Kennedy, who was advising them, would undertake to supply the plans in a fortnight.

FIRE.—Too late for our last issue, Messrs. New and Mayne inform us that there is only a very slight element of truth in the report of a fire having occurred on their premises last week.

FULHAM (LONDON, S.W.).—The adjourned discussion on the report of the Electric Lighting Committee was resumed at the last meeting of the Vestry, and an amendment that the matter be referred back to the Committee to report whether there was reasonable ground for supposing that a combined electric lighting and dust destructor scheme could be installed and worked at a profit without any addition to the rates. Should the Committee be in a position to report favourably on this point they are to select three engineers, or firms of engineers, one of whom is to be consulted by the Vestry on the scheme. An expenditure for this purpose, of £50 is authorised.

INTERNATIONAL RAILWAY CONGRESS.—On Wednesday last the Prince of Wales opened the fifth session of the International Railway Congress at the Imperial Institute, and in the course of his opening remarks referred to the work before the Congress, and pointed out that members would be asked to consider not only the acceleration of passenger trains, but the means of providing for the comfort of passengers, including improved methods of heating and lighting. Arrangements would have to be considered for adding to the safety of the travelling public in such matters as signalling, interlocking, &c., before the members separated. The subject of electric traction and its advantages and disadvantages would doubtless form the subject of careful criticism; and the important topic of light railways, which has lately come to the front in this country, would also be carefully considered. The Prince alluded to the important industries with which the delegates were associated, and hoped that the result of the Congress would be that these interests would derive benefit from the gathering together of so many of those who were in daily touch with the working of the great railway services throughout the world. Mr. Bryce, the ex-President of the Board of Trade, addressed the assembly, and called attention to the examples of engineering skill which the delegates would be invited to visit during their stay in this country. The Congress will sit from June 26th to July 9th. Under the authority of the English section a journal is to be issued daily, giving a full account of the proceedings. The members of the Congress include delegates from all parts of the Continent, America, and the British Colonies and India.

KILLARNEY.—The Town Commissioners are still at cross purposes on the electric lighting question, but Mr. Moriarty at the last meeting succeeded in obtaining the support of the members for a resolution "That, inasmuch as it has more than once been decided in favour of the electric light, we decline to entertain any proposal to retain gas, except for a period of six months." The Killarney Gas Company have been invited to send in tenders for lighting the town for six months.

KINGSWOOD, BRISTOL.—In reference to a statement that the District Council were prepared to treat for the purchase of the electric lighting installation on the Parfitt system at Keynsham, the Chairman of the Council at the last meeting said that there was evidently some misunderstanding. He had only stated, at a previous meeting, that the Council were taking into consideration the extension of their lighting scheme. It was therefore resolved to reply to a letter received on the subject that the Council did not contemplate the immediate purchase of the Parfitt plant. It is stated, however, that the extension of the electric lighting in the district will shortly be considered by a committee specially appointed.

LEEDS.—What may be described as a tolerably fair and very able criticism of electric traction is given in the *Yorkshire Post* of Monday last. The occasion of this *critique* is the presentation of the report of the Tramways Sub-Committee on the question of the system of tramway traction to be adopted by the Leeds Corporation. The report has not received the unanimous assent of the Sub-Committee, and may be taken, the *Post* thinks, as mainly the report of the city engineer, Mr. Thomas Hewson. Exception is taken to some of Mr. Hewson's figures, on the ground that they are unduly favourable to the electric system of traction as against the cable system, which is evidently the one which finds favour with the writer of the article. On the subject of working expenses the writer takes Mr. Hewson severely to task, not so much for his estimate of the working cost of electric cars in general, but for the application of the estimate to the case of the Leeds Corporation tramways. Mr. Hewson's figure of 5·4d. per car mile for the whole of the city of Leeds system is, in the critic's view, an underestimate of not less than 25 per cent. The figures for annual working expenses given in the city engineer's report compare with those of the *Post* as under:—

	Cable.		Electric.
Mr. Hewson's estimate	£101,819	...	£90,072
Revised estimate	83,609	...	108,019

The latter figures are based upon an estimated car mile working expenditure of 7d. for the electric line and 5½d. for the cable line. The writer objects to the comparative figures given in the report, on the ground that there is no electric line in existence working under Leeds conditions. Altogether the criticism is very full and is calmly expressed. If newspaper criticisms on electrical subjects were usually as carefully thought out as this one, the arguments for and against electric traction which from time to time appear in some of our leading journals would be better worth perusal.

Digitized by Google

LIVERPOOL.—A petition of the Corporation to Parliament for leave to introduce a Bill to acquire the undertaking of the Liverpool Electric Supply Company (Limited) came before the Examiner of Private Bills in the House of Lords on Monday last. The Examiner decided to report that the petition had failed to comply with the Standing Orders. A petition on behalf of the Company has been referred to the Examiner of Standing Orders.

LONDON ELECTRIC SUPPLY STATIONS.—The London County Council, at their meeting on Tuesday last, sanctioned the erection of the County of London Company's generating station at Oak Wharf, City-road, and an addition to the Sardinia-street station of the Metropolitan Electric Supply Company; but, with regard to the latter, owing to the fire the complete re-erection of the station will doubtless have to be carried out.

MILE END (LONDON, E.).—The Works Committee of the Board of Guardians reported that they had considered the proposed arrangement of the boiler house, with a view to lighting the workhouse premises by electricity, and as the Board consumed gas to the extent of £1,000 per annum, the Committee recommended that the whole matter be referred back to them for consideration, and that the Vestry be informed that the guardians will be prepared to supply them with sufficient power for lighting the Vestry Hall at cost price subject to the approval of the Local Government Board. The report was adopted.

NATIONAL TELEPHONE COMPANY.—This Company have issued a circular calling attention to a practice, which has been brought to the Company's notice, where non-subscribers are allowed to use the telephone or subscribers receive messages on behalf of non-subscribers. The Company points out that this is in violation of the arrangements entered into between the subscribers and the Company. Although exception has been taken in some quarters to the issue of this circular the warning seems to us a very reasonable one, as doubtless many persons use the telephone who are not entitled to do so. It is only fair, when calling upon the Company to perfect its service and give subscribers full value for their money, that the Company's rights should not be entirely overlooked.

NOTTINGHAM.—The famous museum at Nottingham Castle, and the residence attached thereto, is to be lighted electrically. The work of wiring and supplying fittings has been placed in the hands of W. J. Furse and Co., of Burton-street, Nottingham.

PORTSMOUTH.—A little more than 12 months ago Portsmouth started using the electric light, and is now one of the best lighted cities in the country. Considerable extensions have recently been approved, including the addition of 150 2,500 c.p. arcs for street lighting. The Lunatic Asylum is also to be lighted electrically, and all the police stations are to be connected up with the town mains.

RANGOON.—Messrs. Henry F. Joel and Co. have recently fitted the new Government House for the electric light, to the order of H.M. India Office. Nearly 400 lamps are fitted, 11 of which are 200 c.p. The plant consists of two Joel dynamos and two engines and boilers of Messrs. Davey, Paxman and Co.'s make.

THE ROYAL AGRICULTURAL SOCIETY'S MEETING.—The Fifty-sixth Annual Exhibition of this Society was opened on Saturday last at Darlington, and, except for a disastrous atmospheric visitation on Wednesday, the Exhibition, which closes to-day (Friday), has proved a great success. Amongst the prominent exhibitors may be mentioned Messrs. Clarke, Chapman and Co., Clayton and Shuttleworth, Crossley Brothers, John Fowler and Co. (Leeds), Gilbert Gilkes and Co., Greenwood and Batley, E. S. Hindley, Marshall, Sons and Co., Ransomes, Sims and Jefferies, Robey and Co., and W. H. Willcox and Co. The exhibit of Messrs. Clayton and Shuttleworth includes a 7 B.H.P. petroleum engine which is specially designed for electric lighting, as well as a number of other steam and petroleum engines of various horse-powers. Messrs. Robey and Co. have exhibited a number of engines, including a patent oil engine which it is claimed has been greatly improved since the last Royal Agricultural Society's Show by the substitution of a specially designed lamp for starting the engine, by means of which only 10 minutes are occupied in getting the engine in full work. This firm also exhibited a beautiful model to scale of the compound Robey mining engine, which attracted considerable interest. Messrs. Clarke, Chapman and Co. included in their exhibit two oil engines, one of 8 and the other of 14 B.H.P., of extreme simplicity of design. These engines are entirely self-contained, and carry 10 hours' supply of petroleum, and have a special arrangement of air condenser for cooling the circulating water. One of this firm's compound-wound dynamos, of 150 16 c.p. incandescent capacity, was also on view. Messrs. Crossley Brothers showed both oil and gas engines, one of the former being a portable 7 H.P. nominal, which is claimed to be capable of giving 11 H.P. actual for a consumption of three-quarters of a pint of petroleum per actual horse-power per hour. This engine carries its own water tank exhaust box, &c., and is fitted with four travelling wheels and shafts. The working parts are similar to the stationary type of engine, but the reciprocating parts are so balanced as to ensure the engine running steadily. This engine also carries a supply of oil sufficient for a ten-hours run. At Messrs. John Fowler and Co.'s stand the exhibits included an 8 H.P. combined semi-portable engine specially adapted for electric lighting and similar work where steady running is essential. This firm also exhibited a number of traction and agricultural engines of their well-known make. Messrs. Gilbert Gilkes and Co. showed a variety of "Vortex," "Little Giant," and "Hercules" turbines, including a portion of a 266 H.P. "Vortex." A number of electric motors, from ¼ H.P. to 6 H.P., and a 6-unit dynamo were shown by Messrs. Greenwood and Batley, and Mr. Hindley's exhibit included combined engines and boilers, hoists, pumps, saw benches, &c. At Messrs. Ransomes, Sims and Jefferies' stand, which formed one of the largest exhibits on the ground, engines, combined engines and boilers, and examples of the extensive variety of agricultural machinery and implements for which the firm have so high a reputation were on view, and Messrs. W. H. Wilcox and Co.'s exhibit consisted of an excellent collection of pumps, drilling machines, boiler fittings, oil filters, oils and general engineering accessories.

SHOREDITCH (LONDON, E.C.).—At a meeting of the Vestry on Tuesday last the tenders for the dust destructor apparatus, to be erected in Pitfield-street, in association with the electric lighting scheme, were discussed. Eleven tenders have been received on Mr. Manville's specification, and five of these tenders were selected and laid before the Vestry. The Committee appointed to deal with this matter and Mr. Manville agreed in recommending that the offer of Messrs. Manlove, Alliott and Co., for the sum of £13,250, with an additional £2,500 for the provision of Boulnois and Brodie's patent hydraulic lifts and automatic charging apparatus. This was the lowest tender sent in, and included a system of thermal storage. The recommendation that this tender be accepted was adopted.

SPORTS.—On Saturday last the Athletic Club in connection with Messrs. Crompton and Co.'s Works, at Chelmsford, held their sixth annual bicycle and athletic meeting, and the prizes were afterwards awarded to the successful competitors by Miss Crompton. A liberal prize list and a firework display in connection with the event ensured success.

ST. GEORGE'S (LONDON, W.).—At the last meeting of the Vestry, Mr. Macdonald said he would like the surveyor to prepare a rough estimate of the cost of lighting up the principal thoroughfares of the parish by electricity, so that they might be able to compare the cost with the charge now made for gas. He also complained that the Vestry Hall was still lighted by gas, although almost every other council chamber in the principal towns of the country was lighted electrically. Another vestryman (Major Grimston) suggested that electric light should be provided at the stables, as it would be much safer than gas. The question is to be further discussed before the Joint Committee.

ST. PANCRAS (LONDON, N.W.).—At the meeting of the Vestry on Wednesday a special committee reported against the proposal to borrow £75,000 for electric lighting purposes by means of a public issue of Three per Cent. Bonds guaranteed by the rates. The Vestry, however, refuse to accept this decision as final, and they are making further inquiries as to the cost of negotiating such a loan. Hitherto the London County Council has lent the Vestry money at 3½ per cent.

STOKE.—As a result of the interview between the Chairman and Electrical Engineer of the North Staffordshire Tramways Company and a Sub-Committee of the Stoke Town Council, it has been decided that, subject to the whole of the local authorities in the district being of the same mind and to satisfactory replies being received to inquiries to be made by the Town Clerk from places where overhead traction had been adopted, the Corporation should consent to the introduction of electrical traction by means of overhead wires, subject to the Company giving a satisfactory undertaking to apply for a Provisional Order to extend the present terminus in London-road to Hanford Bridge within a period of two years from the date of the granting of such Order, and that with respect to the undertaking required by the Tramway Company as to the Corporation not exercising their option of purchase under the provisions of the Tramways Act, 1870, at the end of 21 years, the same remain over for further consideration to enable the Corporation to ascertain what such purchase would include.

THEATRE LIGHTING.—The Princess's Theatre, Glasgow, has recently been entirely redecorated and installed with the electric light. The lighting of the auditorium is effected by 130 incandescents of 16 and 32 c.p. Two groups of 15 bulbs are fixed on the ceiling, and by the aid of polished brass and mirrors give an exceedingly brilliant light. The passages, offices, &c., have been fitted up with the electric light, and the stage is shortly to be similarly illuminated. Messrs. Duncan, Stewart and Co (Limited), of Glasgow, have carried out the work, under the superintendence of their engineer, Mr. H. Lyon.

Digitized by Google

THE LIGHTING OF NEWSPAPER OFFICES.—The offices of the *Nottingham Express* are being fitted for the electric light by Messrs. Calvert and Co., of Manchester, the current being generated on the premises.

THE PACIFIC CABLE.—In opening the Queensland Parliament on Tuesday, Sir H. W. Norman, the Governor, said that the question of the Pacific cable was receiving the most earnest consideration of the Queensland Government, and should the researches of the proposed Joint Commission of Great Britain, Canada and Australia justify it, and if the Australian Colonies show further hesitation, the Queensland Government would be prepared to recommend that the Pacific cable be constructed by Great Britain, Canada and Queensland alone.

WALSALL.—The electric current will shortly be supplied to consumers in this town, and the occasion has been taken by the Corporation to issue a pamphlet dealing with the advantages of the electric light over other forms of illumination, and pointing out the various uses to which the electric current can be put. It is stated that the price per unit has been fixed at 6d.

YORK.—In *The Electrician* for May 11, 1894, we gave particulars of the tenders received by the City Council for the electric lighting of this town. A resolution was come to by the Council in that month to the effect that no scheme for lighting the town on the low-tension system be entertained; and the tenders which had been received in response to the Council's advertisement were then reduced to four, viz., those from the Electric Construction Company, the Brush Company, Siemens Bros. and Co., and C. A. Parsons and Co. On May 3rd last we gave particulars of the scheme which then found most favour. This was the proposal sent in by the Electric Construction Company, under which that Company undertook to supply plant, apparatus, and fittings for lighting the city electrically for the sum of £10,865, and to work the plant for a term of three years on the terms set out in the note referred to. At the meeting of the City Council last week the matter was further discussed, and after motions had been made and rejected inviting the Council to adopt the tenders and schemes sent in by the various competitors, it was finally decided that the report be referred back, with instructions to ascertain from the four companies on what terms they would complete the installation and work the plant for a term of years.

"WALKS IN BELGIUM."—An advance copy of a handy little illustrated guide book, entitled "Walks in Belgium," edited by Mr. Percy Lindley, has been sent us. Now that the holiday season is upon us the book should prove useful.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

June 14, 1895.

11,594. M. BINSWANGER and F. G. BELL. London. Improvements in telephone receiver fittings.

11,633. C. W. R. CAMPBELL. London. Improvements in or connected with ceiling roses, lamp holders, and other electrical fittings.

11,641. H. LAVILLE and J. PLISNIER. London. Improvements in electrical alarums.

June 15, 1895.

11,659. J. T. NIBLETT. London. Improvements in elements for secondary batteries.

11,672. J. G. VINE. London. The positive and negative lightning conductor.

11,700. W. C. JOHNSON and L. J. STEELE. London. Improvements in alternating-current machines.

June 17, 1895.

11,708. R. PIPPETTE. London. Improvements in electrically and directly-controlled switches for electricity.

11,728. W. SHAW. Glasgow. Improvements connected with galvanic batteries and switches therefor.*

11,748. F. HODGSON and G. A. EDWARDS. London. Improvements in the application of telephones to electric-bell systems.

11,752. E. ANDREOLI. London. Electro-deposition of gold and silver.*

11,758. C. D. TORRE and F. MANCINI. London. Instantaneous automatic electric lighter for all kinds of gas burners.

11,770. A. J. BOULT. London. Improvements in or relating to telegraphic transmitters and recording apparatus therefor. (C. Spiro, United States.)

June 18, 1895.

11,817. A. CAMPBELL. London. Improvements in apparatus for measuring or indicating the frequency of alternating or pulsating electric currents or potential differences or other periodic disturbances.

11,832. A. J. BOULT. London. Improvements in or relating to secondary batteries. (N. H. Edgerton, United States.)

11,842. P. A. NEWTON. London. Improvements in rheostats and other circuit controllers. (C. Willms, United States.)*

11,864. P. RIBBE. Liverpool. An improved plate for electric accumulators or storage batteries.*

June 19, 1895.

11,892. C. M. HEPWORTH. London. A hand-feed lamp or regulator for the electric arc light for projection purposes.

SPECIFICATIONS PUBLISHED.

NOTE.—All Specifications can now be obtained at the uniform price of 8d. each.

1894.

10,463. MOFFAT. Electric batteries.

13,700. KINGSBURY (Western Electric Company). Telephone switchboard mechanism.

1895.

3,178. MACPHERSON. Testing boxes, &c., for electric mains.

4,497. VON MORSTEIN. Electromagnetic apparatus for operating indicators, &c.

5,700. MACINTIRE. Electric arc lamps.

6,249. BOULT (Kilmore). Aërial electric railway systems.

7,142. MANCHESTER EDISON-SWAN COMPANY and OTHERS. Alternating currents.

7,795. DE DORMAEL. Electric accumulators.

8,590. CARTER. Magnetic ore separators.

NEW COMPANIES, STATUTORY RETURNS, &c.

WIRRAL ENGINEERING COMPANY (LIMITED).—This Company was registered on June 18th, with a capital of £3,000, in £1 shares, to carry into effect an agreement between William Alexander and William E. Thompson, engineers, of Birkenhead, and to carry on the business of mechanical engineers, metal workers, metallurgists, manufacturing chemists, electricians, suppliers of electricity for the purposes of light, heat and motive power, and manufacturers of and dealers in electrical apparatus and appliances.

ELECTRICITY AND ELECTRICAL ENGINEERING NEWSPAPER COMPANY (LIMITED).—On the 11th inst. notice was given by the authorities of Somerset House that this Company had been struck off the register. This step does not in any way affect the present position of our contemporary, the undertaking having been purchased from the Company by Mr. Sidney Rentell more than 18 months ago.

RICHMOND (SURREY) ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—An agreement, dated March 30th last, made between James Worley, of 27, Leadenhall-street, London, E.C., Receiver in the debenture-holders' action of "Clapham v. Latimer Clark, Muirhead and Co. (Limited)," and the liquidator of the said Company (referred to as "the Receiver"), Latimer Clark, Muirhead and Co. (Limited), and this Company, states that whereas the Richmond Company was registered on July 8, 1892, with a capital of £50,000, in £5 shares, to acquire the benefit of a certain contract dated December 8, 1891, between the Corporation of the borough of Richmond and Latimer Clark, Muirhead and Co., for the erection of electric light works and the supply of electric light and power at Richmond; and the Richmond Company have issued 4,067 shares of £5 each, including 1,200 subscribed for by Latimer Clark, Muirhead and Co.; and whereas the latter firm had contracted to acquire certain property and to do certain work for the Richmond Company, but had gone into liquidation while carrying on such work (which work was continued by the Receiver); and whereas the Receiver has therefore a claim of £13,400 (fixed at that amount by arbitration) on the Richmond Company, it has been agreed that of that sum £11,000 shall be paid in cash, and that £2,400 should be credited in respect of calls owing upon the said 1,200 shares. An agreement, dated May 6th, between the Richmond Company and the County of London and Brush Provincial Electric Lighting Company (Limited) (referred to as "the County Company") states that whereas the County Company have agreed to pay the sum of £11,000 referred to in the above-mentioned agreement, it is therefore determined that 2,200 fully-paid shares of £5 each shall be allotted to that concern in full satisfaction for such payment.

SOUTH AFRICAN LIGHTING ASSOCIATION (LIMITED).—The annual return to May 15th has been filed. Out of a nominal capital of £50,000, in £10 shares, 4,070 shares have been taken up, of which 105 have been issued as fully paid. The full amount has been called on the remaining 3,965 shares.

TELEPHONE COMPANY OF EGYPT (LIMITED).—The annual return to May 7th last has been filed. The nominal capital is £100,000, divided into 16,000 Preferred and 4,000 Deferred shares of £5 each; 12,071 of the former and all the latter have been taken up, and 12,000 Preference and the Deferred have been issued as fully paid. The full amount of £355 has been called and paid on the remaining 71 Preference shares.

Digitized by Google

THETFORD ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual return to September 30, 1894, has just been filed. Out of a nominal capital of £5,000, in £1 shares, 3,680 have been taken up, and the full amount paid.

THOMPSON, RITCHIE AND COMPANY (LIMITED).—The annual return to May 3rd has been filed. Of the nominal capital of £5,000, in 200 Preference and 300 Ordinary shares of £10 each, 200 Preference and 140 Ordinary have been taken up, and one-half of these have been issued as fully paid. Upon the remaining shares the full amount has been paid.

VEALE AND COMPANY (LIMITED).—The annual return to December 31, 1894, has been filed; 4,904 shares have been taken up out of a nominal capital of £10,000 in £1 shares, and of these 3,839 have been issued as fully paid. The full amount has been paid on the remaining 1,065 shares.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The annual return to June 6th has been filed. The nominal capital of £1,500,000 is divided into 66,871 shares of £15 each, and 66,258 shares of £7 10s. each; 64,243 of the former and all the latter have been subscribed for and allotted, and the full amount has been called. The total amount of shares for which share warrants comprising five shares each is outstanding is £1,725, and comprising one share each, £180.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The annual return to June 5th has been filed. The nominal capital is £2,445,000, in 600,000 Ordinary, 34,563 First Preference, and 10,000 Second Preference shares of £10 each; 88,321 Ordinary, all the First Preference, and 4,669 Second Preference shares have been subscribed for and allotted. The full amount has been called.

WIGSTON ELECTRICAL AND ENGINEERING COMPANY (LIMITED).—The statutory return to March 4th has been filed. The nominal capital is £25,000, in 2,000 Ordinary and 500 Preference shares of £10 each. Of the 525 Ordinary shares which have been taken up 200 have been considered as having £6 per share paid, and upon the remaining 325 shares £6 per share has been called.

WILLANS AND ROBINSON (LIMITED).—The annual return to April 24th has been filed. The nominal capital is £300,000, divided into 30,000 £5 per Cent. Cumulative Preference shares of £5 each, and a like number of Ordinary shares of similar value; 21,038 of the former, and 19,672 of the latter, have been taken up and allotted, and of these 14,463 Preference and 14,462 Ordinary have been issued as fully paid. The full amount has been called on the remaining shares.

CITY NOTES.

ANGLO-PORTUGUESE TELEPHONE COMPANY (LIMITED). — Coupons No. 15 of the First Mortgage, and No. 10 of the Second Mortgage debentures of this Company will be paid, less income-tax, at Parr's Banking Company and the Alliance Bank (Limited), Bartholomew-lane, London, E.C., on and after the 1st prox.

CALLS DUE.—There is a call of 40 per cent. on £60,000 Debenture stock of the Chelsea Electricity Supply Company (Limited) this day (Friday). To-morrow (Saturday) a call is due of 40 per cent. on £200,000 Debenture Stock of the City of London Electric Lighting Company (Limited); and of £2 per share on the Preference shares of the County of London and Brush Provincial Electric Lighting Company (Limited).

CENTRAL LONDON RAILWAY COMPANY.—During the week this Company, which has been formed for the purpose of constructing and equipping an electric railway between Shepherd's Bush and Liverpool-street, has issued a prospectus inviting applications for 285,000 shares of £10 each. The offices of the Company are 16, Great George-street, London, S.W., and the secretary is Mr. T. Matesdorf. The lists opened on Monday and closed on Wednesday last.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended June 23rd were £794, as against £863 in the corresponding week of 1894, being a decrease of £69. The total receipts for the half-year amount to £23,093, against £22,618 in the corresponding period of 1894, an increase of £475.

CORPORATION STOCK.—To provide for the repayment of debenture bonds issued under the powers of the Local Loans Act (1875) and falling due, and for street improvements, electric lighting, tramways, fire station, and other purposes, the Newport (Mon.) Corporation invite applications for £300,000 Three per Cent. Redeemable Stock, the repayment of which is secured on the whole of the revenues of the Corporation, and ranks as to security with all other securities of the Corporation. The lists closed yesterday (Thursday).

COUNTY OF LONDON AND BRUSH PROVINCIAL ELECTRIC LIGHTING COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend of 6 per cent. for the half-year on the Preference Shares. The dividend is calculated from the due date of payment on the £2 per share paid up, and is payable on the 30th inst. The transfer books will be closed from 1st to 14th July inclusive.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend for the quarter ended March 31st last of 2s. 6d. per share, free of income-tax, payable on the 15th prox. The share register will be closed from July 6th to 13th inclusive. The coupon on the Company's Five per Cent. Australian Government Subsidy Debentures, due July 1st, will be paid on and after that date at Messrs. Barclay, Bevan and Co.'s Bank, 54, Lombard-street, London, E.C. Coupons must be left three clear days for examination.

ELECTRIC ORGAN COMPANY (LIMITED).—Last week this Company issued a prospectus inviting applications for no less than 55,000 Six per Cent. Preference and 37,660 Ordinary shares of £1 each, a total subscription of £92,660, payable 2s. 6d. per share on application, 7s. 6d. on allotment, and the balance three months after allotment. The authorised capital of the Company is £110,000, and particulars of the registration, objects, &c. were given in our last issue. The Company, if it proceeds to allotment, will take over and carry on upon an extended scale the business of a previously incorporated concern called the Hope-Jones Electric Organ Company (Limited). The offices (*pro tem.*) are 17, Coleman-street, London, E.C., and the Secretary is Mr. A. W. Speed.

GREENWOOD AND BATLEY (LIMITED).—The annual general meeting of this Company was held on the 22nd inst., at the London offices, 16, Great George-street, S.W., Mr. Arthur Greenwood presiding. The Chairman, in moving the adoption of the Directors' report, said he regretted to state that the results of the past year's trading had not been satisfactory, although they were more so than those submitted last year. They had earned the interest on debentures and, in addition, a small profit. Fortunately, there was no actual loss to record, and they had been able to make some allowance for depreciation, which they were unable to do last year. With reference to the item of stock in hand, which amounted to £63,234, the proportion of machines finished, in progress, and the actual orders showed a decrease of £11,000. As the result of the year's working, instead of a loss of upwards of £8,000, shown in the previous year's accounts, there was a small profit. In the current year they had secured many more orders up to the present time than in the corresponding period of last year. The report was adopted.

LIVERPOOL ELECTRIC SUPPLY COMPANY (LIMITED).—A meeting of the shareholders of this Company was held on Saturday last, at Exchange Station-buildings, Liverpool, when resolutions were passed (1) confirming the agreement entered into with the Corporation for the sale of the Company's undertaking; (2) authorising the application to Parliament in the present session for the necessary Act to carry the above agreement into force, and for the appropriation and distribution of the assets of the Company. The sale is subject to the extension of the city boundaries being carried through in the present session, and it will enable the Company to distribute among its shareholders a sum equal to £8. 2s. per share. The resolution will require confirmation at a subsequent meeting.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 23rd inst. amounted to £1,245. The amount for the corresponding week last year was £820. Increase, £425.

SALT LAKE AND OGDEN GAS AND ELECTRIC LIGHT COMPANY (LIMITED).—Notice is given that the coupons of the Six per Cent. First Mortgage bonds of this Company, due July 1st, will be paid at the National Provincial Bank of England, Bishopsgate-street, London, E.C.

STOCK EXCHANGE NOTICES.—Application has been made to the Stock Exchange Committee to appoint a special settling day in, and to grant a quotation for, 10,277 Ordinary shares (Nos. 1 to 10,277) and £60,000 Four and a-Half per Cent. Debenture Stock of the Chelsea Electricity Supply Company (Limited).

WEST COAST OF AMERICA TELEGRAPH COMPANY (LIMITED).—The coupons due 30th inst. on the debentures of this Company will be paid by Messrs. Barclay and Co., Lombard-street, E.C., and should be left three days for examination.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended June 21st, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,436.

WESTERN UNION TELEGRAPH COMPANY.—The following is the report of this Company for the quarter ended June 30, 1895:—The following statement exhibits the condition of the Company at the close of the quarter ended March 31, 1895:—

Surplus January 1, 1895, as per last quarterly report		$7,531,628. 92
Net revenues, quarter ended March 31, 1895		1,163,781. 08
		$8,695,410. 00
From which—deducting for dividend of 1¼ per cent. paid April 15, 1895...	$1,191,936. 25	
Interest on bonded debt	223,400. 00	
Sinking funds........................	19,991. 00	
		$1,435,327. 25
Left a surplus April 1, 1895, of		7,260,082. 75
The net revenues of the quarter ended June 30th, based upon nearly completed returns for April, partial returns for May, and estimating the business for June, will be about		1,600,000. 00
		$8,860,082. 75
From which, appropriating for—		
Interest on bonds	$223,400. 00	
Sinking funds	20,000. 00	
		243,400. 00
		$8,616,682. 75
It requires for a dividend of 1¼ per cent. on capital stock issued, about		1,191,940. 00
Deducting which leaves a surplus, after paying dividend, of..		$7,424,742. 75

In view of the preceding statements, the Committee recommend the payment of a dividend of 1¼ per cent. on the capital stock of this Company on July 15th next, which may be collected through any bank on or after that date.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 894. [No. 10. Vol. XXXV.] **FRIDAY, JULY 5, 1895.** PRICE SIXPENCE.

NOTES.

We understand that the Telephone Committee, in view of the Dissolution, will not make any specific recommendations to Parliament. Had it done so it would, we believe, have been a case of Balak and Balaam. Instead of anathematising the National Telephone Company and all its doings, the Committee would in all likelihood have pronounced something not altogether unlike a blessing. As it is this unexpected consummation will be avoided, and the evidence taken will be merely reported to Parliament.

Our Paris Correspondent announces this week the passing of a law relating to electric light and power conductors. The only noteworthy feature of the *projet de loi* just adopted by the Senate is the institution of a permanent Advisory Council, half the members of which are to consist of representatives of the electrical industry. The function of this Advisory Council will be to assist the Minister of Commerce in drawing up the inevitable rules and regulations, and to solve all electrical problems which that official may find too difficult for his own unaided capacities. This rigid organisation of a body of advisers by formal legislative act is very characteristic of the French fondness for precision, and the spasmodic and informal way in which the Board of Trade seeks outside advice whenever and wherever it is required is equally characteristic of our own preference for flexibility.

Certainly in adopting the French plan the electrical industry could no longer complain that all rules and regulations emanated from the fertile brain of a single official. But in that, we think, lies the sole advantage of a regular Advisory Council. With us, after a due period of brooding, the Departmental regulation egg is hatched, and the unfortunate young chicken is sent out into the electrical world, which has an official permission—nay, a positive invitation—to criticise and grumble, up to a certain date, without stint. By this rude process, supplemented by a Round Table conference, we ultimately secure a set of rules which, if they do not command universal assent, have at any rate gone through the fire of universal criticism. On the other hand, a permanent Advisory Council, such as is proposed across the Channel, would in all probability prove a stumbling block and rock of offence by reason of its very permanency. In such an august body youth and freshness would in all probability be at a discount, and the Board of Trade, instead of obtaining the advice of the entire electrical industry as it does now, would only have the benefit of out-of-date opinions. Rough and ready criticism would, moreover, be discountenanced as something disrespectful to such a venerable and representative body. And withal *sub-rosâ* grumbling would not be prevented; the Advisory Council would, we may be sure, contain either too many professors or too many manufacturers, or too many consultants, or too many theorists to please this section or that section of the industry. So long as the Board of Trade shows itself open to advice to the same extent as hitherto, we need not envy our French friends their Advisory Council of electrical engineers.

We are quite at one with municipalities in resisting the disfigurement of handsome thoroughfares by the erection of ugly contrivances intended to facilitate public locomotion, and even a Pottery township would not be without excuse in opposing anything in the shape of the hideous American span system of running trolley wires. On the other hand, it would have to be a remarkably handsome street the appearance of which would suffer appreciable injury from a row of delicate-looking ornamental rolled-steel columns run down the centre of the roadway, and supporting on either side a wire no thicker than No. 00 B.W.G.; indeed, the minutest demand from the public for more rapid transit should outweigh such a bare possibility of æsthetic debasement. That being so, it is difficult to see what it is the Dublin Corporation has to congratulate itself on in preventing the introduction of electric traction on the overhead wire system into the sacred precincts of the Irish capital. As related in our "Parliamentary Intelligence" this week, the net outcome of their opposition to the Bill of the Dublin United Tramways Company has simply been that the various clauses relating to Dublin and to the townships of Rathmines, Rathgar and Pembroke have been struck out, thus making the Bill apply only to the cacophonous but level-headed localities of Clontarf, Drumcondra and Glasnevin, Kilmainham and Rathfarnham. A very small dose of the spirit of compromise should have enabled Dublin to have been as up-to-date as Kilmainham, and nevertheless to have preserved the amenities of its streets.

Those who are still concerned about the old A. T. *v.* B. T. controversy will note with some interest the skirmish which recently took place before a Select Committee of the House

Digitized by Google

of Lords. Much was said as to the suitability of alternate currents for transmission purposes and as to the large number of alternate-current transmission plants in existence in America and on the Continent; but as the point at issue was the suitability of alternate-currents for distribution to printing-press and medium-sized motors, the relevancy of such evidence is not altogether apparent. However, as the Strand Company secured its Order the irrelevancy of much of the opposition evidence has only an academic interest.

"The Bidard Battery. No lead, no sulphuric acid, no paste." On reading this portentous announcement one is tempted to exclaim "Eureka!" and to hasten to learn how to escape from lead batteries, with their attendant ills. The description of the Bidard battery, however, tends to chasten one's enthusiasm; it is a zinc-carbon couple in a sulphate of zinc solution, an arrangement we seem to have heard of before. But, according to the inventor, the chemical reactions in his cell are a little remarkable, oxygen being given off at the positive electrode, while suboxide of zinc is deposited at the negative. Prof. Bidard mentions that the generally received theory is that zinc oxide is composed of zinc and oxygen, but he prefers to regard it, on the strength of the working of this cell, as a compound of a suboxide of zinc and oxygen. Recently we have had the gravity Daniell cell discovered in a very slightly modified form by an Italian doctor, and also the original Planté cell composed of two thin sheets of lead wound spirally round each other; and now we have the brilliant discovery of the French *savant* recorded above, and yet there are people to be found who are not impressed by the rapid advance which science is making at the close of this 19th century.

"One of the most remarkable episodes in municipal government ever known came to an end last night," says the New York correspondent of *The Times* in a cablegram dated June 30th. "Since February 13th, the Mayor of New York has been an autocrat, with power of official life and death. A Bill then passed by the State Legislature gave him power to remove heads of city departments and subordinates, this being thought the only way in which Tammany officials could be weeded out and pure government insured. . . . Out of 16,000 municipal servants, less than 3,000 have been removed, and of these less than 300 were of high rank. The changes, none the less, amount to a revolution." We trust that the necessity for a municipal Dictatorship may never arise on this side of the Atlantic; but its occurrence in New York might well give pause to that extravagant laudation of municipalisation, especially if it seems likely to lead to the giving out of contracts, which is so much met with in some electrical quarters. We can understand the contractor's and consultant's predilection for the municipalising of all things, but that is no reason for anyone else to short-sightedly advocate the multiplication of municipal functions with its inevitable corollary the multiplication of municipal functionaries.

The life's labours of the late Prof. Huxley had indeed nothing to do with electrical science, but it may, nevertheless, be permissible to point out in this connection that if modern science is to make sure of the ground it has so painfully conquered, the popularisation of science must not be neglected. It is not every scientific mind that can profitably apply itself either to original research or to practical or educational work; and with the example of a Huxley before him no man need think it beneath him to bring the leading lines of scientific thought attractively within the comprehension of the average man. Unless it be broad-based upon the people's understanding the scientific edifice we are all so proud of will ever be liable to be toppled over like a house of cards by a wave of ignorant prejudice.

Cable Interruptions.—There are no cable interruptions to report this week.

King's College, London.—The Michaelmas term of this college commences on October 3rd. Further particulars will be found in our advertisement columns.

International Telephonic Communication.—Negotiations are, it is reported, in hand with reference to the establishment of a telephone line between Constantinople and Sofia.

Personal.—Viscount Peel, Viscount Wolseley, and Sir John Pender, M.P., were presented on Wednesday with the freedom of the burgh of Kirkwall, at a public meeting held in the Town Hall.

Electric Lighting Provisional Orders Bills.—In the House of Lords on Thursday, June 27th, the Royal Assent was given in the usual manner to the Electric Lighting Provisional Orders Bills Nos. 1, 2 and 3.

The Manhattan Railway.—It is announced that the Westinghouse Company have received the order for the electric equipment of the Manhattan elevated railroad in New York. The cars are to be heated as well as lighted by electricity.

The Parallel-Series Control.—On Sunday the legal term of existence of Dr. John Hopkinson's patent No. 2,989 of July 7, 1881, will come to an end. The subject of this patent is the coupling of two or more motors in series or parallel for varying the speed of vehicles.

The Niagara Falls Scheme.—The New York correspondent of *The Times* states that the first power electrically transmitted for commercial purposes from Niagara Falls was sent on Monday to the aluminium works a mile distant. Four thousand horse-power was delivered and used.

The London County Council's Tramways Bill.—The Bill of the London County Council, empowering them to work the tramways acquired by them, was to have been considered by Lord Belper's Committee, but it has been withdrawn from the group, and will not be further proceeded with this Session.

Telephonic and Telegraphic Communication in Switzerland. At the end of 1894 the length of the Swiss State telephone lines amounted to 7,843 kilometres, this being an increase of 1,071 kilometres on the year. On the other hand, the State telegraph lines decreased during the year to the extent of 65 kilometres, the total length of the telegraph lines now in operation being 7,203 kilometres.

Calcium Carbide.—In a recent number of the *Révue Générale des Sciences* M. Moissan claims priority over Mr. L. Wilson, of America, in the commercial preparation of calcium carbide. M. Moissan states that whilst his first research on an electric reverberatory furnace with movable electrodes was published in the *Comptes Rendus* of December 12, 1892, Mr. Wilson only took out his patent in America on February 21, 1893.

Electric Elevated Railways for Chicago.—It is stated on good authority, says the *Western Electrician* of Chicago, that the Directors of the Lake Street Elevated Railroad Company of Chicago have definitely decided to work the line by electric power. A contract has been entered into by which the West Chicago Street Railway Company will furnish electric power to the Lake Street people at 10 per cent. over the cost of production.

Digitized by Google

Institution of Civil Engineers.—The new edition of the list of members of the Institution of Civil Engineers contains the names of 19 honorary members, 1,873 members, 3,726 associate members, 351 associates, and 816 students—together 6,785. Mr. H. L. Antrobus, Dr. William Pole, F.R.S., and Mr. James Forrest have been reappointed to the posts they have held for so many years as treasurer, honorary secretary, and secretary respectively.

Obituary.—The death is announced of Mr. Henry W. Frye, late of the *Electrical World's* editorial staff. He died at Folsom, New Mexico, on June 20th. Last September Mr. Frye had an attack of pneumonia, and in January of this year went to New Mexico to recuperate. Mr. Frye graduated from Colby University, Maine, and took the electrical course under Dr. Louis Duncan, at Johns Hopkins University. He joined the staff of our contemporary in April, 1892.

London, Walthamstow, and Epping Forest Railway.—Earl Morley's Committee of the House of Lords has passed the London, Walthamstow, and Epping Forest Railway Bill, under which power is conferred to improve the scheme as authorised last year by tapping the Tottenham and Hampstead Junction Railway. The measure also authorises the creation of £280,000 additional share and loan capital, which, added to that already sanctioned, makes a total of £2,410,000 share and £770,000 loan.

German Wiring Rules in Austria.—At a recent meeting of the Elektrotechnischer Verein of Vienna, the German wiring rules proposed by the Verband Deutscher Elektrotechniker (see *The Electrician*, May 24th, p. 116) were discussed, and several amendments were proposed. The Verein has asked the opinion of the larger electrical firms of Austria, and they all agree with the proposed amendments. The German rules, it is thought, will be of considerable importance to the Austrian electrical trade on account of the great trade with Germany.

Absolute Measurement of Electrical Resistance. — A Correction.—In the concluding paragraph of our report of Prof. Viriamu Jones' lecture (*The Electrician*, June 21st, p. 257) the following sentence occurs:—"With such a machine standards of from a thousandth to a two thousandth of an ohm may be measured to nearly the same percentage accuracy." The sentence should run—"With such a machine standards of from a thousandth to a two hundred thousandth of an ohm may be measured to nearly the same percentage accuracy."

Double Refraction of Electric Rays.—In *Wiedemann's Annalen* for June, Prof. A. Righi, of Bologna, makes reference to Herr K. Mack's communication on this subject (see *The Electrician* of February 22, 1895, p. 502), and states that on May 27, 1894, he himself presented a Paper to the Bologna Academy of Science on the same subject describing the same kind of experiments. Prof. Righi believes that his own Paper was unknown to Herr Mack at the time of his experiments, and he is glad to see his own results on the double refraction of electric rays confirmed.

Current Views on Energy.—In the current number of *Wiedemann's Annalen* a special note is published by the editors with regard to the subject proposed for discussion at the next annual meeting of the Society of German Naturalists and Physicians which is to held at Lübeck on September 17th. At last year's meeting at Nuremburg it was resolved that the subject should be made known beforehand, especially when theoretical discussions have to take place. The subject for this year's meeting is "A Survey of the Current Views on Energy," by Prof. Helm, of Dresden.

The Hookham Meter.—Notice has just been given under the Patents, Designs and Trades Marks Acts, 1883 to 1888, that Mr. George Hookham has applied for leave to further amend the specification of his meter patent, No. 4,225 of 1887. Any person may give notice of opposition to the amendment at the Patent Office within one calendar month from the 26th ult. The claims of the patent are ten in number, and it is desired to strike out the second claim, which is for "compensating for magnetic drag or friction, or for both, by compound winding either the armature or the magnets." The reason given for this striking out is that the patentee is advised that the subject matter of the claim was not novel at the date of application.

Fire-Damp Explosion in an Austrian Mine.—In his report on the "Johannschacht" explosion Dr. Riel maintains that the fire-damp was exploded by a broken miner's glow lamp, the parts of which were found on the spot. Herr Feilendorf states, on behalf of the lamp makers, that after the most elaborate experiments with a miner's electric lamp, he found that he could not fire explosive gases even by breaking the bulb. This statement is, however, contradicted by Herr Spoth, who says that as far back as 1890 Le Chatelier ascertained that a filament at white heat easily explodes any gas or damp. In some experiments made with a small glow lamp for 5·6 volts and 0·5 ampere, when a small hole was made into the bulb no explosion took place, but with a larger hole it occurred at once.

Condensers on Electric Light Mains.—In our issue of June 14th our Paris Correspondent called attention to the fact that some Boucherot condensers were in commercial use on the mains of the Secteur Électrique des Champs Elysées. We understand that so far only two condensers have been used, and these experimentally. One condenser, having a capacity of eight microfarads—that is to say, giving at a pressure of 3,200 volts and a frequency of 40 ∾ the apparent output of 20 kilowatts—remained for one day upon the mains, but owing to heating it had to be cut out. The second condenser, of 2·5 microfarads, or 6·6 kilowatts apparent output, remained on the mains for 12 days, when it had to be cut out owing to an accident. It is proposed after modifications to replace these condensers.

Beetles and Arc Lights.—It seems that the arc lights in the little American town of Lancaster have recently attracted the attention of an immense swarm of what a local entomologist defines as "members of the family of water beetle." What possible interest a flood of water beetles can have in an arc does not transpire, but certain it is that the inhabitants of Lancaster awoke one morning to find carcases of these aquatic Coleoptera lying by bushels at the base of the lamp-posts. "The bugs," as the Americans impolitely call them, "would charge in solid column" against the arcs, filling the interiors of the globes to the total interruption of their normal duty. When daylight came, the remnant which was to be saved returned to its native pond and hid itself "in the deep mud." Similar visitations have been reported from time to time from other towns using arc lights.

Electric Drilling.—An interesting application of electricity to drilling is recorded by the *Street Railway Gazette*. The Glens Falls (N.Y.) Street Railway Company have built a portable electric drill, which, while a somewhat homely combination so far as appearances go, has answered admirably the purpose for which it was constructed. It is used in drilling holes for bonds in the webs of rails. The electric motor which furnishes the power has a capacity of ½ H.P., and is mounted on a platform wheelbarrow. Current is secured from the overhead trolley wire and ground connection is made to the rail. The armature is connected with an intermediate shafting to reduce the speed. From the latter a flexible shafting extends which is connected with the drill. The feed is regulated by a thumbscrew located at the back of the drill. It is stated that by the use of this device a hole can be bored in the rail in less than a minute.

The Telephone in Sweden.—A correspondent of the *Daily News* states that the Swedish State telephone authorities are about to combine the telephone with the State telegraph system. In Sweden everybody is, as we know, "on the telephone." In future every subscriber will be allowed to make use of his telephone address as his telegraph address. The letter "Rt" (Rikstelefon) will be transmitted free of charge, and the telegraph office receiving a message will look up the addresses in the telephone register, and send it on. This will save two or three words in every telegram. Further than this, telephone subscribers will be allowed to telephone on their messages to the telegraph offices for transmission, and they can, if they so desire, have their telegrams telephoned on to their house immediately they arrive. The State hopes to save by this arrangement, as the number of messengers will be reduced. They also hope to do an increased telegraph traffic.

An Electrical Pumping Plant.—A novel electrical pumping plant at Monroe is described in a recent number of the *Engineering and Mining Journal* of New York. The great variation in height of water in the river rendered it necessary to have a changeable location for the pumps in order that the suction pipe should be always sufficiently submerged. With this end in view a railway reaching well into the river at low water was built. Upon this railway, mounted on a four-wheeled truck, a pump house was constructed. This house contains an 8in. by 10in. triplex power pump, driven by a 15 H.P. slow-speed electric motor. With the rise and fall of the water the position of the pump house on the railway is changed by means of the windlass at the head of the railway. Necessarily in such an installation as this, provision had to be made for connecting the pumps and discharge pipe, and this has been accomplished by extending the main the entire length of the railway and putting flanged tees at regular intervals. At these points the connection between the pump and main is made. In order to supply the necessary current for operating the motor a pole line was erected alongside the railway. On this are strung the wires which carry current to the motors.

Magnetic Asbestos.—In an article on the above subject in the current number of *Wiedemann's Annalen*, L. Bleekrode, of the Hague, says that experimenting with some of Bell's asbestos he found that its magnetic properties were even more marked than was the case with the sample mentioned by Mr. A. C. C. Swinton in *The Electrician* of September 7, 1894, inasmuch as no strong electro-magnet was necessary, but an ordinary steel magnet was sufficient to demonstrate the existence of magnetism. It is remarkable, he continues, that though this material has been handled so much in the last few years, its magnetic properties have remained unobserved. Faraday, in his investigations on the magnetic behaviour of different substances, classed asbestos as a slightly magnetic material, which is rather remarkable, as he used a strong electro-magnet. Even in 1778 Brugmans, who discovered the magnetic properties of bismuth, described asbestos as fairly strongly magnetic. He mentioned that the steel magnet used would carry on each pole about 1·5 kilogrammes. He knew also that different kinds of asbestos were not equally magnetic. L. Bleekrode, employing an electro-magnet having a tractive effort of 5kg., found that asbestos strips 40mm. long and 3mm. wide were attracted even at a distance of 10mm. These strips afterwards exhibited slight polarity. L. Bleekrode points out that of course the substance may contain iron, but he has boiled some grey asbestos for several hours in concentrated sulphuric acid and it still retained its magnetic properties.

A Central Station in a Thunderstorm—Mr. T. P. Wilmshurst, borough electrical engineer at Halifax, has sent us the following interesting account of a recent experience at the Halifax Corporation Electricity Works, which seem to have come in for an undue share of attention from the terrific thunderstorm of Wednesday afternoon last week. About 5:30, during the height of the storm, two house transformers about 1½ miles from the works appear to have been struck and broken down to earth, blowing their fuses. A few minutes after a blinding flash appeared to strike the alternator which was running, and disabling three armature coils, went to earth by jumping the air space, and thence through the shaft and bed-plate. Two of the staff who were leaning against the guard rails (which, however, were not connected to the alternator) at the same moment experienced sharp shocks. By this time the water was rushing in torrents down the steep slope leading from the tower to the works, and entering the boiler house, quickly rose within a few inches of the fires. By dint, however, of pluck and hard work, the staff on duty were able to stem the torrent and save the fires. In addition to this one of the sub-stations became flooded to a depth of over 5ft., completely immersing the 20-kilowatt transformers, low-tension switches, and circuit fuses. These were under water for 15 hours, during which time they took no harm, supplying current to the network as usual, and when examined next day were found perfectly dry inside the cases. They were supplied by Messrs. C. A. Parsons and Co., Newcastle. It is satisfactory to learn there was no interruption of the supply except for a few seconds required to put on another alternator.

The New Caledonia Cable.—We take the following extract from an exceedingly interesting article on New Caledonia which recently appeared in a London local paper. The article is from the pen of an Englishman associated with the New Caledonia cable-laying expedition :—

"The project of connecting New Caledonia by cable is not of recent origin. In 1878, after the great Canaque insurrection, when over 200 whites were massacred in one week, the French Parliament voted a grant towards it, but upon the suppression of the insurrection, and as the fear of the Canaques gradually died out, so the scheme receded into the background, to be revived from time to time, but only carried into execution last year after prolonged negotiations initiated, and played a prominent part in by the Hon. Audley Coote, who for so many years now has advocated cable communication between Canada and Australia across the Pacific. The cable follows the shortest route between New Caledonia and Queensland, connecting Gomen Bay in the north-west point of the island with the town of Bundaberg (some 180 miles north of Brisbane), which promises shortly to attain considerable importance through the growth of the sugar-producing industry in this district. It is owned by the Société Française des Télégraphes Sous-marins, and is worked by them under joint subsidies from the Governments of France, New South Wales, and Queensland, having been constructed and laid for that Company by the Société Générale des Téléphones—now merged into the Société Industrielle des Téléphones. As regards the submersion of the cable, suffice it to say, that under exceptional difficulties of weather, the entire work was carried out to the satisfaction of the governments concerned, whilst the reception accorded to the expedition in Australia testified in itself as to its popularity there. One of its indirect advantages, from the Australian point of view, is that it will enable the escape of convicts to be made known at once in Australia, thus checking, if not preventing, their landing on those shores. At the instance of the Queensland Government, meteorological bureaus, working in conjunction with their own meteorological department, have been established in the island, whence, through the courtesy of the Cable Company, weather observations are now exchanged with the Australian continent several times daily by cable. This international work is expected to prove of essential service on both sides in forecasting storms and hurricanes, the latter of which are often most disastrous in their effects locally. What would our own meteorologists not give for such an advanced post 800 miles out in the Atlantic? In every respect will New Caledonia benefit in having at length realised that means of communication with the outer world, which by its far-reaching effects has so revolutionised the diplomatic and social intercourse and the commercial dealings of nations."

Telephonic Development in Germany.—The *Elektrotechnische Zeitschrift*, in a recent issue, published some interesting tables showing the present state of telephony in Germany. At the end of 1894 there were 398 urban telephone systems, with 100,441 subscribers. These were composed in the following way:—13 towns with more than 1,000 subscribers, 11 towns from 500 to 1,000, 79 from 100 to 500, 64 from 50 to 100, 194 from 10 to 50, and 27 only from 2 to 9 subscribers. The total number of messages per day is, on an average, 1,041,581. The following detailed figures with regard to the more important figures, are of interest:—

	Subscribers.	Total No. of messages per day.	Messages per subscriber.
Berlin	22,069	223,211	10
Hamburg	8,995	153,903	17
Dresden	3,265	57,689	17
Leipzic	3,290	95,812	29

If we compare these figures with the English ones as given in *The Electrician* of May 31st we find that the number of messages per subscriber is higher in Leipzic than in any town in England; Leeds, the most talkative town, only coming up to 26 messages per subscriber. There are in Germany in all 165 long-distance telephone lines, having a total length of about 8,000 miles. The longest lines are: Berlin-Memel, 620 miles; Berlin-Cologne, 390 miles; Berlin-Munich, 450 miles; Berlin-Vienna, 410 miles; Berlin-Frankfort, 390 miles.—Herr Vollmer, of the Imperial Telegraph Service, speaking at a recent meeting of the Electrotechnische Gesellschaft of Frankfort-on-the-Main on the development of long-distance telephony, said that in 1885 Herr Münch proposed to cross the conductors, and the results were so favourable that on the Berlin-Magdeburg line, which is about 186 miles long, not the slightest noise was perceptible. With the introduction of bronze wires a great impetus was given to long-distance telephony. The first silicium-bronze long-distance conductor in Germany was that between Berlin and Hamburg, which was 3mm. in diameter. Later on conductors of 1·5mm. were used.

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

(Continued from page 219.)

To Determine Steam Consumption when Non-Condensing.—To determine the weight of steam consumed by an engine when it is not fitted with a condenser, or when it has a jet condenser, the feed water must be measured. In this test it is, of course, essential that the boilers shall supply no other engine than that under test. Even then, however, the test is liable to be vitiated to some extent by the fact that some of the feed water will not pass into the engine, but will escape through the safety valve or the pipe joints or by condensation. To make the test successful, therefore, attention must be paid to these points, and precautions must be taken to minimise the losses arising from them.

The usual preparations for this test are as follows: The feed pumps are arranged to take their supply of water from a large temporary tank, shown at A in Fig. 72, through the pipe B. Over this large tank a somewhat smaller tank is placed, there being a delivery pipe and stop valve, C, communicating between the upper and lower tanks. The bottom of the upper tank should be so shaped as to allow of the whole

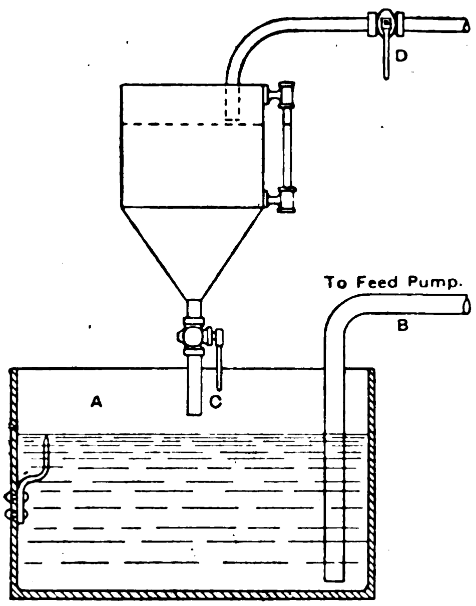

Fig. 72.

of the water in that tank freely flowing through the delivery pipe. A supply pipe, D, connected to the water main and provided with a stop valve, is arranged to supply water to the upper tank at intervals. There is a gauge glass in the side of the upper tank, with a mark near the top of the glass; and there is an index on the inside of the lower tank, to show when the water in it is at standard height. Both the tanks should be of ample capacity in relation to the size of engine, or the fillings are liable to be too hurried and error is likely to arise. The capacity of the upper tank, at the level of the gauge mark, is carefully measured; and the supply of feed water is passed into the lower tank by alternately filling and emptying the upper tank, care being taken that the upper stop valve is quite closed before the lower one is opened, and *vice versâ*.

These preparations completed, the boilers and engine must be run for a considerable time before the test is commenced. When everything is arrived at a fairly steady condition of working, the test may be commenced. At this moment the level of water in the bottom tank must be accurately brought to the standard gauge mark, by letting a little water flow into it from the upper tank or by baling a little out. At the same time, the level of water in the boiler gauge glasses must also be carefully noted, as it will be necessary to stop the trial at the same level. As it is impossible to measure the boiler water level very accurately, it will be necessary to reduce the importance of any change in the level of the water in the boiler to a very trifling quantity. This is done by carrying on the test for a very long time, generally exceeding eight hours. For example, suppose the difference of boiler level represents 500lb. of water, this would be a serious item in a short trial, because it would bear so large a proportion to the weight of water measured in the tanks; but if the trial is double or treble this length, the seriousness of the variation of water in the boiler becomes proportionately diminished. A very long trial makes it negligible. It will be seen, too, that the length of the trial must to some extent depend on whether the boiler is bulky or of small capacity in proportion to its steaming power; but it is rarely wise to place confidence in a trial of less than six or seven hours' duration.

During the test, the times at which the upper tank is emptied into the lower must be tabulated. It will be well to take indicator cards from time to time, and to note the times at which they are taken. If the steam consumption per horse-power is to be determined, the engine must be kept at as constant a load as possible during the test, and frequent repetitions of Tests I. and II. should be made. When the test is nearing its completion, everything should be gradually brought back as nearly as possible to the condition at the start, *i.e.*, the boiler pressure and water level must be adjusted, and the feed pumps should be regulated to their former speed. When the test ends, the level of water in the lower tank must be the same as at starting; or, if it is not, the quantity of water required to make it so must be measured.

To Determine the Quality of Steam.—Nothing, perhaps, is more reprehensible, from the scientific point of view, than the practice which is common among engineers and engine makers, of specifying the merits of an engine in terms of its consumption of steam without giving any information whatever about the quality of the steam. Yet, it is not at all an uncommon thing to compare two engines merely by quoting their relative steam consumptions in pounds of steam per hour. Whether the steam supplied is wet in one case or dry in the other; whether it is at a high pressure or at a low pressure; whether it is or is not superheated, are matters very rarely entered into in the comparison. Yet they are matters of supreme importance. To obtain a complete thermal balance-sheet both the quality and the quantity of steam must be determined.

If the steam is known to be superheated, the degree of superheat can quickly be obtained by taking the pressure and temperature of the steam with calibrated thermometer and gauge. A comparison with Regnault's table gives the result. If the steam is saturated, the dryness factor can be determined in one of two ways: by calorimetry, or by means of a good separator. The latter method, which consists in passing the steam through a separator and weighing the amount of water abstracted, the weight of steam being determined by condensing it or in any other convenient way, is suited to cases where there is much wetness, or where the steam is required to be only roughly tested. Where accurate results are desired, or where the dryness factor is likely to be high, some form of calorimeter must be used.

Steam calorimeters are, in general, of two kinds: the condensing and the throttling calorimeter. Fig. 73 shows a form of Barrus condensing calorimeter, made by Messrs. Musgrave and Sons. The sample of steam is drawn from the steam-pipe—which Prof. Carpenter recommends should be vertical, not horizontal—through the bent pipe E. From this it passes the thermometer I, which will indicate its temperature, and the gauge, which will show its pressure, to the spiral tube or worm D. This worm is contained within a cooling chamber, A, through which cold water is kept flowing; and the condensed steam in the worm passes away, past the thermometer G, to a weighing tank. The condensing water is let into the chamber A, past the thermometer F, and it passes the thermometer H on leaving it. The difference between the readings on these two instruments, therefore, gives the rise in temperature of the cooling water. After passing H, the cooling

* From a forthcoming work to be published by *The Electrician* Printing and Publishing Company. All rights are reserved.

Digitized by Google

water flows into a weighing tank; or it may be metered into the instrument. Calling k the required dryness factor, L the latent heat of the steam at the pressure shown on the gauge, w the weight of condensed steam, W the weight of condensing water, and t_1, t_2, t_3, and t_4 the thermometer readings on I, G, F, and H respectively, then we have—

Heat lost by steam condensed $= w\,(k\,L + t_1 - t_2)$, and

Heat gained by condensing water $= W(t_4 - t_3)$.

Assuming there is no loss of heat by radiation, or in any other way, these two amounts of heat are equal, whence—

$$k = \frac{\frac{W}{w}(t_4 - t_3) - (t_1 - t_2)}{L} \quad . \quad . \quad . \quad . \quad . \quad (95)$$

Before any measurements are commenced, it is necessary that the calorimeter shall be in action long enough to raise every part to a steady temperature. It will also be necessary, where accurate results are desired, to have the pressure gauge tested against a mercury column, and to have the thermometers calibrated.

The wire-drawing calorimeter was first proposed by Prof. Peabody. Its action depends upon the drying and superheating effect when steam is throttled. The sample of steam is throttled through the calorimeter, and its pressure and temperature are measured, the degree of throttling being adjusted to produce a few degrees of superheat. It will be

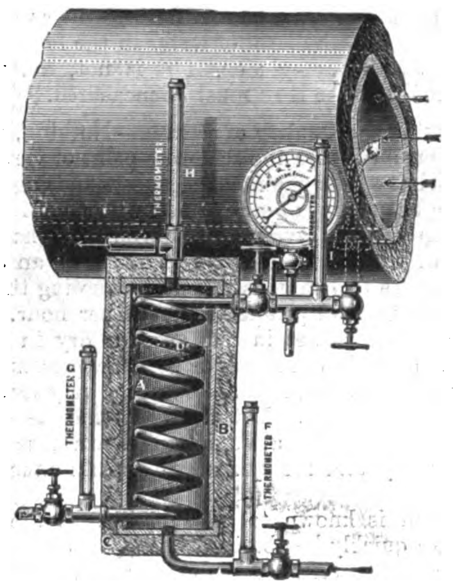

FIG. 73.—Musgrave Steam Calorimeter.

seen that, unless the dryness factor is very high, the amount of throttling which is available may be quite insufficient to dry the steam. In fact, the method is of very limited application.

Some attempts have been made to estimate the degree of wetness of steam by the so-called "salt test." This test consists in introducing a known weight of a given salt into the boiler, and then estimating the percentage of salt contained in the sample of steam drawn off. It will readily be seen that the comparison of the amount of salt primed over with the steam is no guide whatever to the degree of wetness of the steam, since some or all of that wetness may be due to subsequent condensation of dry steam. More than this, the salt test seems to be utterly unreliable; repetition of the test upon the same boiler, under precisely the same conditions, giving results which may differ as much as several thousands per cent.! Clearly, the salt test is not worthy of its name, and the publication of results obtained by it should be received with great caution.

Some care must be directed to the method by which the sample of steam is drawn from the steam-pipe. There is no little risk of the orifice of the tube, inserted for the purpose of obtaining a sample, acting as a kind of steam separator, drawing off too great a proportion of steam, and allowing the water to fly past the test tube uncaught. This will chiefly happen if the orifice of the test tube is in the plane of the motion of the steam. On the other hand, if the test tube is bent, as shown in Fig. 73 at E, so as to oppose its orifice directly to the stream of steam, the action of the edges seems liable to draw more than the fair proportion of water with the sample of steam. Under no conditions should the orifice of the test tube be expanded into a funnel or horn. On the whole, the most reliable results seem to be obtained with a test tube carried into the very centre of the steam-pipe, and bent at right angles, as shown in Fig. 73. To some extent the error due to the action of the orifice might be eliminated by working with two different sizes of test tube inserted consecutively.

The $\theta\,\phi$ Diagram.—We shall conclude this section by describing some of the more practical uses of the temperature-entropy diagram in steam engine testing. The reader is advised to refer back to Vol. XXXII., p. 545, for particulars of this diagram in its general thermodynamic relations, before passing on to consider the following applications to steam and steam engines.

From equation 68 it follows that when unit mass of water is raised from a temperature θ_1 to a temperature θ_2, the increase in entropy will be

$$\phi = \log_\epsilon \theta_2 - \log_\epsilon \theta_1 \quad . \quad . \quad . \quad . \quad . \quad (96)$$

Accordingly, the $\theta\,\phi$ diagram of water is a logarithmic curve. In Fig. 74, let one pound of water be taken at an absolute temperature of 600°F., and let its temperature be

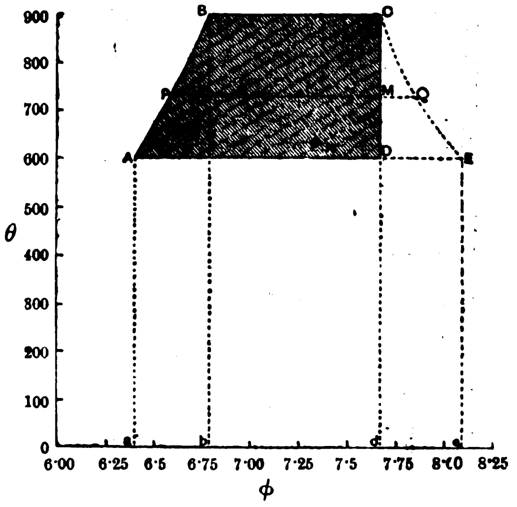

FIG. 74.

raised to 900°F.; then the $\theta\,\phi$ diagram of the process will be represented by the curve, A B. When at the condition, B, let this pound of water be converted into dry steam, at constant pressure. The process is isothermal; therefore, a horizontal line, B C, will represent it in the diagram, the length of this line being, by definition of entropy, equal to the ratio of L—the latent heat at 900°F—to the temperature at which the change takes place, *i.e.*, 900°. At the point, C, we have one pound of dry steam. A total amount of heat equal to the area a A B C d has been supplied to the water, of which the area b B C d represents heat spent in turning it into steam. To transfer this pound of dry steam to the cylinder of an engine need involve no change either in temperature or entropy, so that the point, C, will represent steam at the point of cut-off in the cylinder. Expansion now follows, and the character of the further portion of the diagram will depend on the character of the expansion. Let us first assume that this latter is isentropic or adiabatic; and let the steam be expanded down to the temperature at starting, *i.e.*, 600°F. Evidently the vertical line, C D, will meet the case, and at the point D we have adiabatically expanded steam—partly steam and partly water—at a temperature of 600°F. The line D A represents the conversion of the whole of the steam into water, the initial state A being now arrived at, and the cycle being completed.

Digitized by Google

During the condensation an amount of heat represented by the area D A *a d* is given up by the steam to the cooling agent, and is wasted. The shaded area A B C D, therefore, represents the mechanical work done in the cylinder.

Now let us suppose that instead of being expanded adiabatically the steam is expanded so that it remains dry saturated steam throughout the period of expansion. The expansion curve will be represented by C D, such that any point, Q, on it is at a distance, P Q, from the horizontally opposite point, P, on C D, which is equal to the ratio of latent heat to the temperature corresponding to the point. In other words, the relation of Q to P will be exactly the same as that of C to B. Therefore, C E is the dry steam expansion line, or the saturation line on the $\theta\ \phi$ diagram. As a consequence, the horizontal distance, M Q, at any point will represent the wetness of the steam at that point, when adiabatic expansion takes place; the ratio of M Q to P Q being the proportion of water, and the ratio of P M to P Q being the proportion of true steam, to the total mass of wet steam. And the ratio of A D to A E will represent the final dryness factor of the adiabatically expanded steam.

These considerations hold whatever the form of the actual expansion line. If, instead of either C D or C E, it takes another course, the horizontal departure of that line from the line C E will always enable the degree of wetness of the steam to be determined, the assumption being that the steam is initially dry. A further point is afforded by these considerations, namely, that although more work can be obtained by means of the saturation expansion than by means of the adiabatic expansion—the total area of the diagram of work being A B C E, instead of A B C D, in the former case—the efficiency is lowered by the change; for the ratio of the area of *work* to the area of *total heat expended* is diminished.

(*To be continued.*)

TWO-PHASE PLANT AT THE PANTIN WORKS OF MM. WEYHER ET RICHEMOND.

BY GASTON ROUX.

A very interesting two-phase plant has recently been laid down in the workshops of MM. Weyher et Richemond at Pantin, near Paris. MM. Weyher et Richemond, who have acquired a good name as makers of machinery, last year bought the Brown patents, and in making use in their workshops of a two-phase system of power distribution, they desired not only to prove the advantages of the system, but also to avail themselves of such advantages.

The Weyher and Richemond works consist of a number of buildings covering an area of about 25,000 square metres (6 acres), and they originally derived their power from three steam engines, viz.:—One fixed single cylindrical condensing 80 H.P. engine, one fixed compound condensing 120 H.P. engine, one semi-fixed compound condensing 50 H.P. engine. Although the new plant has been in operation for about seven months, the change over has only been made bit by bit, and is not yet finished, so that the compound engine is still running until the last 45 H.P. motors under construction are erected.

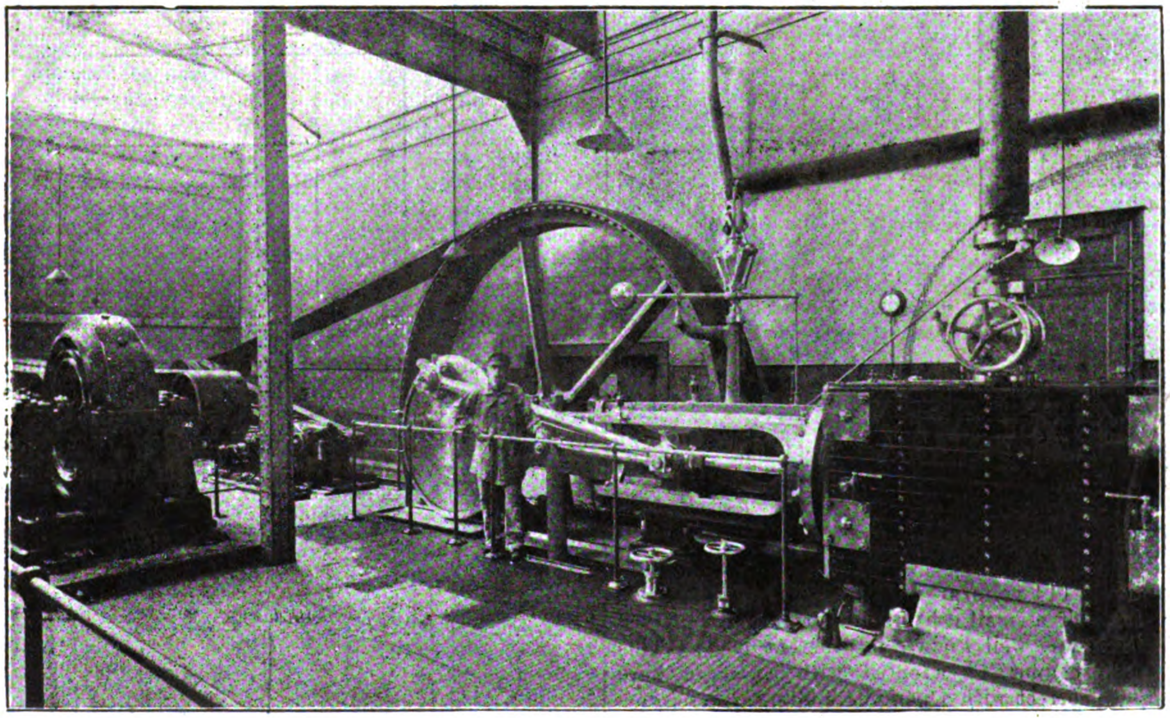

FIG. 1.—400 H.P. Steam Engine driving the Two-phase Plant at the Pantin Works.

The new plant includes five boilers, three of which are sufficient to supply the steam to the engine; the two others are used for the purpose of making steam-engine tests in the room adjoining the boiler room, and to feed a vertical steam engine for testing the dynamos. The single steam engine for the power plant is of the horizontal single-cylinder type (*see* Fig. 1), provided with four valves. It can generate 400 H.P. at 60 revolutions per minute, its point of economical consumption being at 200 H.P. It operates a line of shafting furnished with pulleys for—(1) A continuous-current 110-volt 100-ampere dynamo used as an exciter for the alternators, and capable of yielding 50 additional amperes for electrical tests; (2) a small three-phase machine originally used to operate an electric crane, now made to serve for tests on three-phase motors in the testing room; (3) three 130 H.P. alternators. One of these alternators is provided with a "Bovet" magnetic clutch (see *The Electrician*, Vol. XXX., p. 509, March 3, 1893). The shafting extends on the right side in the dynamo testing room, and a pulley attached to its extremity enables it to be operated by

Digitized by Google

means of the 150 H.P. vertical engine in the event of the horizontal engine proving defective; but during the seven months it has been in operation such a necessity has not arisen. This shafting is certainly superfluous. It is quite probable that one alternator on the flywheel would have given as satisfactory results as a high-speed alternator. But at the time when the installation was organised the arrangement described was found preferable.

All the alternators are of 88 kilowatts, and give 110 volts and 400 amperes; they are provided with 12 outside poles, and at 400 revolutions per minute give 40 ∿. The following is a comparison of these machines with continuous-current dynamos of the same power and same speed, and, of course, of the same manufacture. Firstly, as to price, they are cheaper by 10 to 15 per cent.; they are very light (about 4½ tons) and of great simplicity. As to their efficiency, it is the same as that of continuous-current dynamos. A polyphase alternator works absolutely under the same conditions as a dynamo; it is a dynamo less the collector. Efficiency measurements have been obtained by measuring (*a*) the necessary excitation to obtain 110 volts at full load, (*b*) the resistance of the armature hot, (*c*) the loss by friction, resistance of the air, hysteresis and Foucault currents, the machine reversing in the same field as

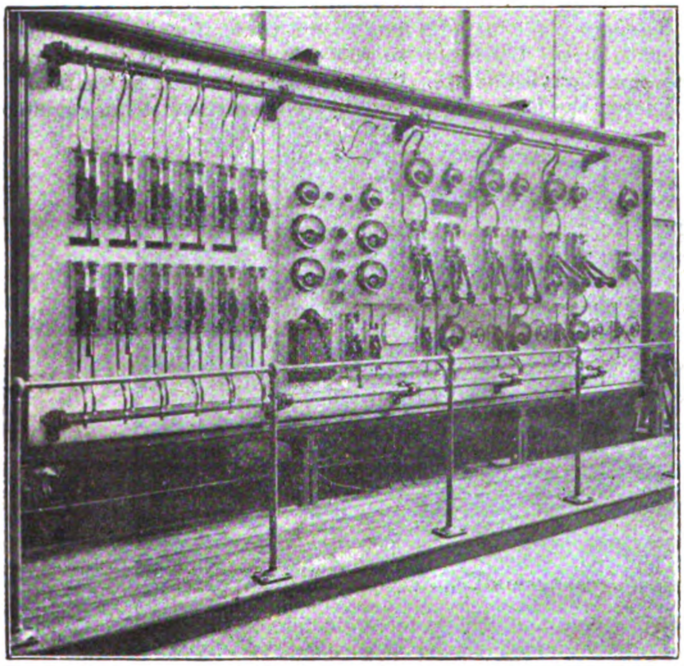

Fig. 2.—Switchboard.

that which produces 114 volts at no load. These losses were measured by means of a small continuous-current dynamo, the efficiency of which was well known at different loads. This proceeding, which cannot be adopted with a single-phase alternator, is quite correct with a polyphase alternator.

The following table gives the results of these tests:—

—	Full load. (Watts.)	Half load. (Watts.)	One-tenth of load. (Watts.)
Loss in the armature	2,280	570	20
Loss in inductors	1,520	1,460	1,400
Friction	640	640	640
Air resistance	1,000	1,000	1,000
Hysteresis	1,160	1,130	1,100
Foucault and internal currents	1,760	1,700	1,600
Utilised power	88,000	44,000	8,800
Total power	96,360	50,500	14,560
Efficiency per cent.	91·3 %	87·2 %	60·5 %

By suppressing the movement of the air produced by the arms of the armature, the efficiencies would be respectively 92·3, 89, 65 per cent. It has not, however, been found advisable to suppress this movement of the air, which keeps the machine room well ventilated. In taking into account the efficiency of the exciter, the figure 91·3 decreases to 91·2.

The paralleling of the alternators is effected by means of incandescent lamps according to the well-known plan. This operation is very easy, and is effected on the switchboard, where

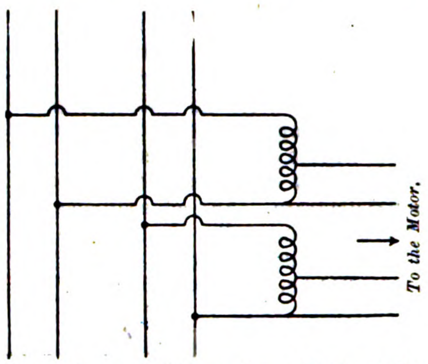

Fig. 3.—Diagram of Connections of Motor at Start.

are to be found (*see* Fig. 2) on the right the switches of the machines running to "bus" bars, on the left the switches of the different circuits, and in the middle the measuring and synchronising apparatus. Paralleling experiments have been tried several times in my presence, and have always been successful.

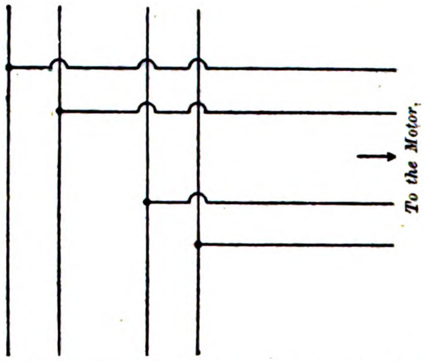

Fig. 4.—Diagram of Connections of Motor when Running.

The distributors consist of eight cables, 75 square millimetres in section, two by two in parallel. The cost of the line is of so very little importance, in comparison with other expenses, that there was no hesitation, in order to completely separate the two phases, to carry out the distribution with four

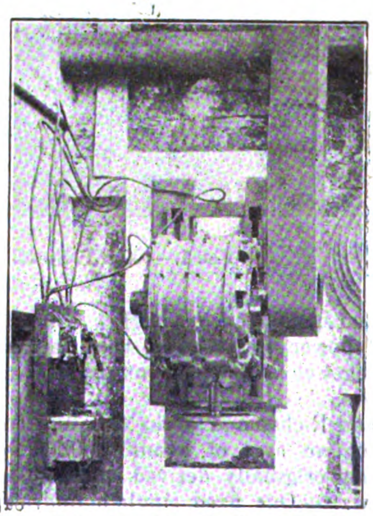

Fig. 5.—30 H.P. Motor Provisionally Erected in the Brazing Shop.

double wires, when it would have been sufficient to use three double wires of the same individual section. The multiplication of cables must not be set down to the use of the two-phase system, but to the awkwardness of having to deal with cables of more than 100 sq. mm. cross section.

Digitized by Google

The motors employed are of two types, "squirrel cage" and with resistance in the armature. The starting of the "squirrel cage" motors is carried out in the following manner. In order that no disturbance may be produced in the mains, the starting current must not exceed the normal current, but then the torque is one-quarter or one-fifth of that required. It is necessary to send into the motor a current greater than that derived from the line. To obtain this a self-induction coil, provided with five or six layers of wire, is placed in shunt on each section of the line; the motor is then inserted between the first and

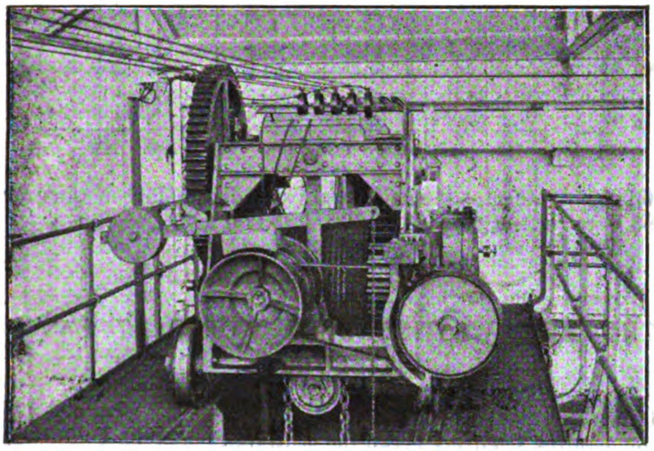

Fig. 6.—Hoisting Gear of Electric Travelling Crane.

third layers, and the desired result is obtained. As soon as the motor has attained its normal speed, the self-induction coil is suppressed by the movement of a switch, and the motor is placed directly on the main line. This apparatus is similar in principle to the "compensator" of Elihu Thomson used for three wire alternating distribution. The sketches (Figs. 3 and 4) show the connections of the motors on starting and when speeded up The starting of the motors with resistance in the armature is done in the same way as that of continuous-

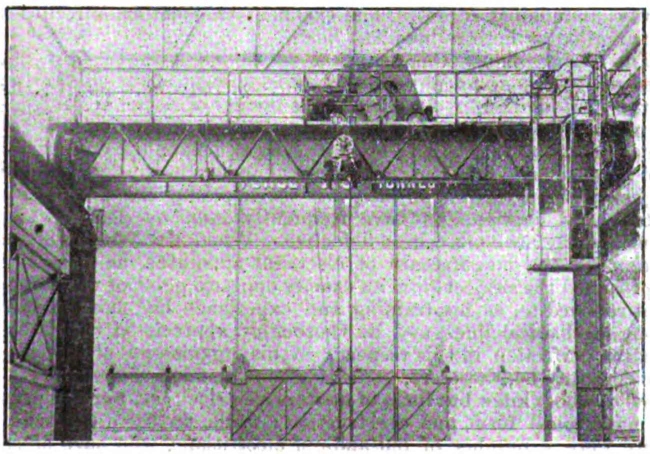

Fig. 7.—General View of Electric Travelling Crane.

current shunt motors. Nevertheless, before starting either of these motors it is preferable to stretch the belt so that the motor attains its normal speed more rapidly.

Two generators work all day in parallel at 200 H.P., and as this load corresponds to the point of most economical consumption of steam, the average result is excellent. At night the third alternator, used in the day time as a reserve, is brought into operation for supplying the lighting current, the lighting being carried out by 60 arc lamps and 600 incandescent lamps.

This plant has been erected by M. P. Boucherot, and does the greatest credit to this young engineer, who has already acquired fame for his novel applications of alternating current.

There are some 17 motors in the shops distributed in the following manner. (*See* also Figs. 5, 6 and 7):—

HYSTERESIS, FRICTIONAL AND EDDY-CURRENT LOSSES IN CONTINUOUS-CURRENT DYNAMOS.

BY GEORGE ADAMS.

The simple method of determining hysteresis, frictional and eddy-current losses, originated by Mr. Gisbert Kapp, is probably well known to most electrical engineers.

The method may be briefly stated as follows:—Run the dynamo as a motor, exciting the field from a separate source, and keeping the excitation constant. The speed of the motor may be varied by varying the voltage of the current supplied to the armature. The current required to run the

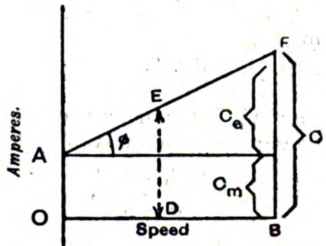

Fig. 1.

armature light is so small that the armature reaction may be neglected, and also its resistance. The measured voltage at the brushes may therefore be considered equal to the armature E.M.F. Take readings of speed (S), current (C), and voltage (e). By increasing the voltage we increase the readings. Plot the current readings as a function of the speed. Thus at B (Fig. 1) make B F equal to the current at speed O B. At any other speed D plot the corresponding current D E. Join the points F E, and produce the line backwards until it cuts the vertical axis at A. Then $OA = C_m$ represents the current at zero speed. The resistance due to hysteresis and friction is independent of the speed of the armature when once in motion, therefore we may consider the current C made up of two parts, namely, C_m required to produce the torque which just balances the resistance due to mechanical friction and magnetic hysteresis, and $C - C_m = C_e$ required to produce the torque which balances the resistance of eddy currents.

If W_m = loss in watts due to mechanical friction and hysteresis,

W_e = loss due to eddy currents.

We have the total measured loss—

$$W = W_m + W_e,$$
$$W = e\,C,$$
$$W_m = e\,C_m,$$
$$W_e = e\,(C - C_m).$$

We are thus able to determine by means of a simple experiment the eddy current, and frictional and hysteresis losses when the machine is on *open circuit*.

Digitized by Google

For the same strength of field the hysteresis loss is proportional to the speed, and the same holds good for the frictional losses, provided the speed be not reduced too much. The eddy current losses being proportional to the square of the E.M.F.'s producing them, must for the same strength of field be proportional to the square of the speed. A diagram showing at a glance the relation between speed, volts, current and watts lost in hysteresis, friction and eddy currents, for a given dynamo, may be constructed as follows :—

Let the abscissæ represent the volt readings, or speed of machine, and the ordinates represent losses in watts. The abscissæ in Fig. 1 will to a suitable scale represent the volt readings, and we have the relation $\frac{C_e}{e} = \tan \phi$, ϕ being the angle included between the lines A C and A F in Fig. 1. Also $W_e = e\,C_e = e^2 \tan \phi$. Now, $\tan \phi$ is a constant which can be obtained from the readings taken of current and volts, and is, in fact, equal to $\frac{C - C_m}{e}$. Having experimentally determined the numerical value of $\tan \phi$, we can construct the curve O E (Fig. 2), from the equation $W_e = e\,C_e = e^2 \tan \phi$. The curve O E is a parabola having its axis at O Y.

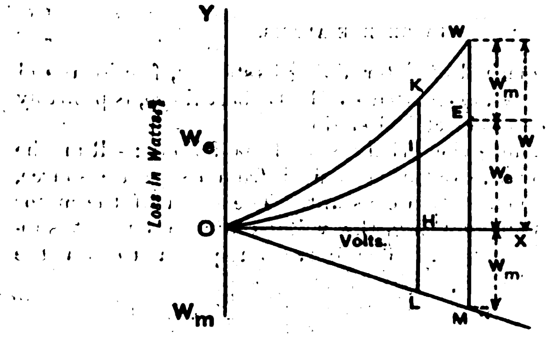

Fig. 2.

Now, $W_m = e\,C_m$, and C_m is found by the construction Fig. 1, or it may be obtained at once from the following formula :—

$$C_m = \frac{S\,C_1 - S_1\,C}{S - S_1},$$

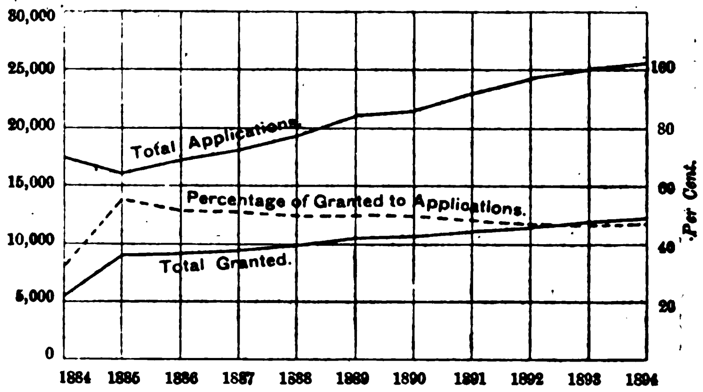
where S = speed corresponding to current reading C, S_1 = speed corresponding to current reading C_1. S should be about normal speed, and S_1 about half speed.

Next plot the value of W_m corresponding to any volt reading, and draw a line from this point through the origin O. Since the loss by friction and hysteresis varies as the speed, the ordinates of the line O M thus found will represent the watts lost in hysteresis and friction for the voltage represented by the corresponding abscissæ. If a curve O W be constructed by plotting the ordinates of the line O M, such as H L above the ordinates of the curve O E, and joining all the points thus obtained, the ordinates of the curve O W will represent the total loss in watts, including frictional, hysteresis and eddy-current losses, the abscissæ being either volts or speeds corresponding to the volt readings. The ordinates of the curve O E represent eddy-current losses.

PATENTS IN 1894.

During last year 25,386 patents were applied for as against 25,116 in 1893, an increase of a little over 1 per cent. It will be seen from the accompanying diagram that the number of applications for patents, which in 1884 amounted to about 17,000, have increased by 48 per cent. in 10 years. During 1894 the names of 11 gentlemen were added to the register of patent agents, the total number of agents upon the register now being 236.

The total income of the Patent Office in 1894 amounted to close upon £182,000, £163,447 being derived from patent fees alone. The total expenditure amounted, in round figures, to £96,000, salaries accounting for £55,000 and printing for nearly £20,000. The surplus for 1894 was, in round figures,



£86,000. The total income, total expenditure and surplus for 1893 were respectively £175,000, £95,000 and £80,000.

THE NEW WESTINGHOUSE WORKS AT EAST PITTSBURG.*

It is almost six months since the Westinghouse Electric and Manufacturing Company began the centralisation of its Pittsburg, Allegheny and Newark factories at its new plant in East Pittsburg. Owing to the vast amount of machinery and material to be transported, the transfer has been necessarily slow, but the new factory is now in complete operation. Soon after the consolidation of almost all the competing electric companies into the General Electric Company, the Westinghouse secured a plot of land adjoining the main line of the Pennsylvania Railway, 12 miles east of the city of Pittsburg. Here, as the result of a year's work and the investment of many hundred thousand dollars, there has been erected one of the largest and most complete manufacturing establishments in the world. The situation of Pittsburg is particularly advantageous for any manufacturing concern supplying the American market, for being well inland it is convenient to both the East and West; moreover, it is in the centre of a great coal-producing district; many raw materials are near at hand and consequently cheap; the labour market is of the highest grade and always abundantly supplied, and excellent transportation facilities are afforded by both railway and boat.

The Westinghouse Company was incorporated in 1886, and at present it has permanent representatives in most of the chief cities of the United States. A glance at the history of electrical development will show that the manufacturing branch of the business has been controlled very largely by those who also made the discoveries and inventions. Involving, as electrical apparatus does, a grasp of higher mathematics and physics, it is not surprising that mechanical details and construction have frequently been overlooked, and consequently have often been defective. When Mr. Westinghouse undertook the manufacture of electrical apparatus, he naturally approached the subject from an exactly opposite point of view from that referred to, as his training and experience had been largely along mechanical lines, and he thoroughly appreciated the necessity for perfection in this respect; in his organisation of the electric company he, therefore, gathered about him a staff of engineers, some of whom knew but little of matters electrical, but were experts on mechanical form and construction; while, on the other hand, there were a number of out-and-out electricians, who have since attained world-wide reputations. It is due to this associating together of the two classes of men that there has resulted an engineering department whose work has won for the Westinghouse Company the enviable reputation that its apparatus is as efficient mechanically as it is electrically.

After a detailed account of the engineering record of the leading men on the Westinghouse Company's staff our contemporary proceeds to describe the factory itself.

The main building of the Westinghouse plant is 754ft. in length, 231ft. in width and 67ft. high to the ridge of the central roof truss. Along either side of the building, 25ft. above the floor, run galleries 80ft. in width. The accompanying illustration (Fig. 1) gives a general view from one end of the shop, showing very clearly the interior arrangement. The warehouse is 574ft. in length, 76ft. wide and 62ft. in height. The building is of the same general design as the main building, and connected to the latter, on the

* Abstract from the *Electrical World* of New York, to whom we are also indebted for the blocks illustrating our abstract.

Digitized by Google

second floor, by means of five enclosed bridges. Directly behind the warehouse is the power house. Behind the power house is a two-story building 258ft. long, 76ft. wide and 62ft. high, used, on the ground floor, for storing and annealing sheet iron. The second floor is devoted to the punching department, about 60 machines being there employed. One of the latest types of these is an armature ring press made by the E. W. Bliss Company. A special feature of this press is that the knock-out pads are operated by a device which obviates the use of springs and consequent strain at a time when the machine is doing its maximum work. For sharpening the dies of the larger presses a special emery grinder is used, made by the Springfield Emery Wheel Company, Springfield, Mass. ; the emery wheel of this grinder has an oscillating motion, so that each time the die being sharpened passes beneath it there is a change in the surface presented for grinding, thus ensuring an absolutely true ground surface. It is the intention of the Company to still further extend its works by the erection of an iron foundry in the rear of the main buildings. At present all the castings are made in the Allegheny factory, where also the Sawyer-Man incandescent lamps are being manufactured.

Between the main building and the wareroom is a brick and iron building, completely fireproof, four stories in height, 187ft. long and 25ft. wide, used as a paint shop, drying room, and oil house. Back of the main building is the temporary carpenter and box-making shop, 192ft. by 60ft. by 32ft. Alongside of the punch shop, and 300ft. east of the main building, is a blacksmith shop, and also a temporary brass foundry, the former 241ft. by 80ft. by 45ft., the latter 241ft. by 40ft. by 26½ft. The six principal and permanent buildings are of brick and iron fireproof construction throughout. The floors are slow burning, and designed to sustain 500lb. to the square foot. All the buildings are most pleasantly located and completely lighted by double windows 10ft. wide, situated every 16ft. along the side, and by large skylights every 32ft in the roof.

The arrangements for heating the buildings are of the most improved type. Steam radiators are located at points just under the roof, and 80in. Sturtevant blowers are used to force the heated air through distributing pipes 36in. in diameter at the heaters, and made gradually smaller as the air is distributed. There are two of these blowers in the warehouse, six in the machine shop, and one in the punch shop, all being driven by Westinghouse two-phase motors. For supplying the radiators exhaust steam from the engine is ordinarily used, but reducing valves are also connected so that live steam may be admitted to the pipes in case of necessity. Filtered drinking water is distributed throughout the various buildings by pipes connected to a 10,000 gallon filter. For the purpose of providing convenient and quick intercommunication between the various departments and offices there is a local telephone system, with instruments in each office, and a small exchange located in the west end of the warehouse. Long-distance lines connect the factory with the Pittsburg Central, and another local wire runs to the city office of the Westinghouse Company.

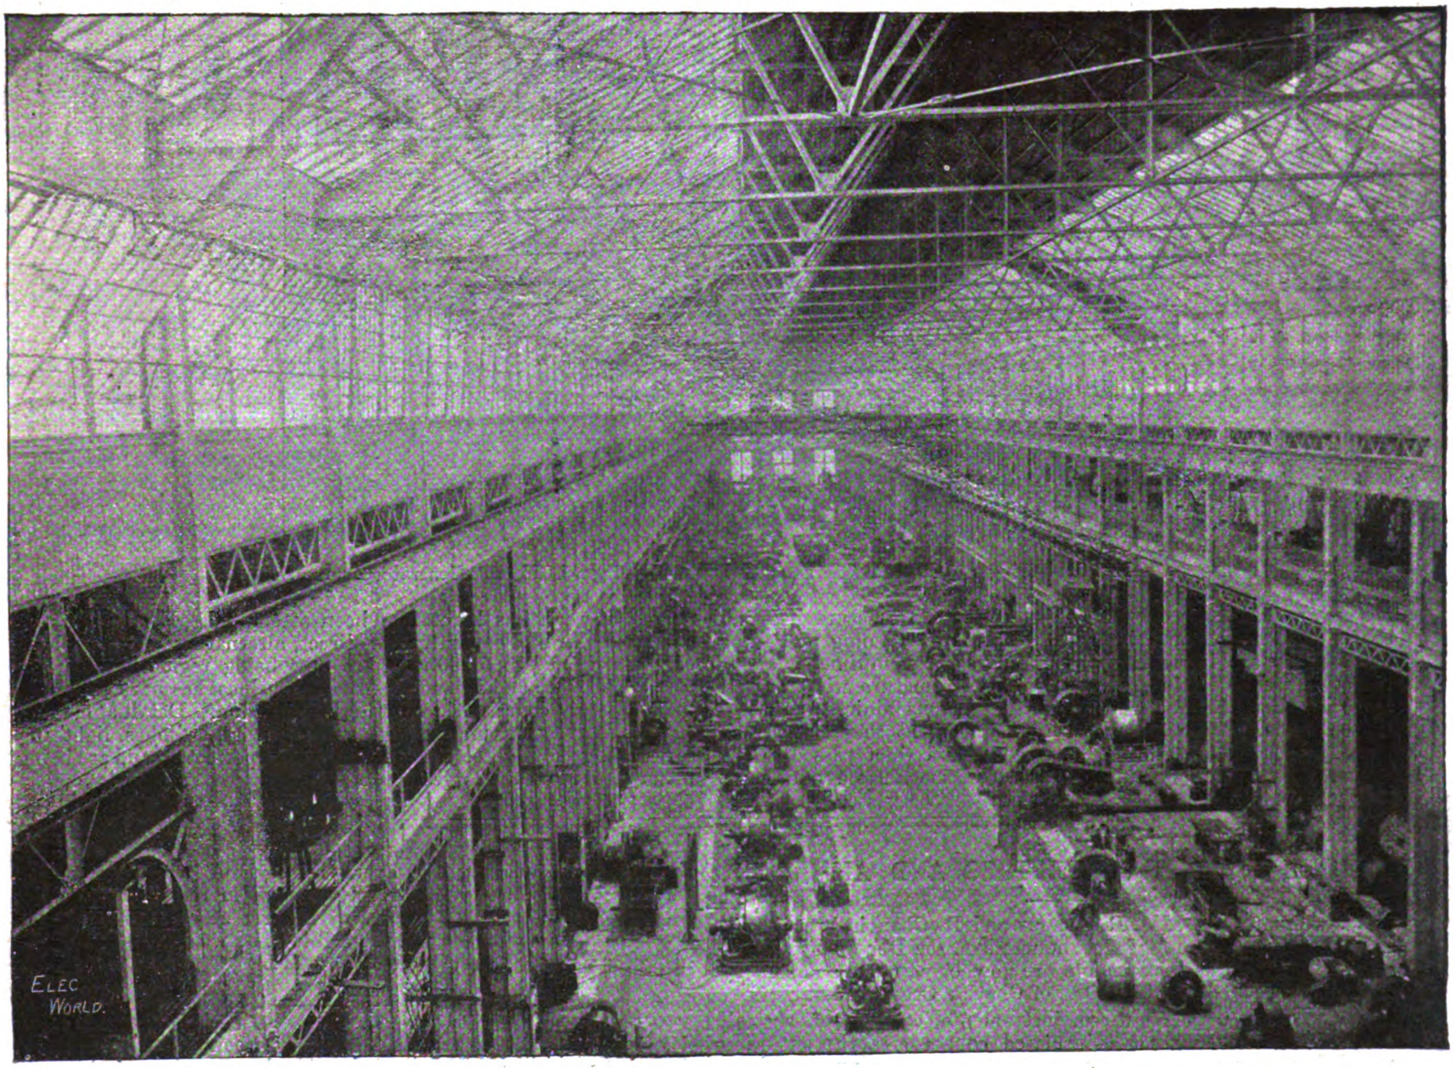


Fig. 1.—New Westinghouse Works at East Pittsburg, Main Aisle of Machine Shop.

All machinery throughout the factory is driven by two-phase electric motors conveniently placed. Despite the fact that motors are used for power, and that they are placed as near as practical to the machines they are to drive, there is necessitated, nevertheless, almost a mile of shafting in the machine shop alone.

Near the end of the main aisle of the machine shop is a new and large 122in. lathe, 30ft. between centres, made by Wm. Sellers and Co., Philadelphia ; the machine is shown (Fig. 2) boring the field of a 1,000 H.P. alternator and turning off the armature of a 1,050 H.P. direct-current machine, both at the same time. The Westinghouse Company has always made an object of having special tools for its work, thereby effecting economy in time and cost of manufacture and securing uniform and interchangeable parts ; for the new works many additional special tools have been designed, one of which noted in passing through the works, finishes off motor castings at one cut. For the purpose of making and repairing the

Digitized by Google

tools required, there has been organised a very complete and extensive tool department, where over 130 employés are kept constantly at work making and replacing all sorts of tools, thus saving for the Company the profits which otherwise accrue to tool manufacturers. Another interesting department is the experimental room, where a number of the most capable men are constantly employed experimenting and carrying on original research. For their use has been fitted up a room most admirably adapted for its purpose. Here are conveniently available direct, alternating, and polyphase currents of any desired voltage, and of any number of alternations. There has also been erected a special glass-protected room for carrying on experiments with high potential currents running up to 50,000 and 60,000 volts pressure.

The entire arrangements in the factory are most admirably fitted for manufacturing apparatus quickly and with the minimum amount of labour. Take, for example, section "A," in which the street car motors are built. In one end of the section the armature discs and shafts are received and built up. The lathe turning and filing departments are immediately adjoining, so that no time or labour is lost in transportation. Next come the armature winders, and following them the men who are employed in machining and fitting up the fields. After the motors are assembled they are turned directly over to the testing department and then passed to the packers, so that the manufacture of these machines is an almost continuous operation from the building up of the armatures cores to boxing the motors for shipment. All the apparatus is manufactured in accordance with this same system, and in consequence there exists throughout the factory the most complete order and business-like *régime*. The organisation of the employés is equally thorough. There is a head foreman in charge of each of the general sections, and under him assistant foremen for the sub-divisions into which the work is divided. The system under which the men work and earn their wages is best fitted to make them industrious and energetic. The whole system has been most thoroughly studied and admirably developed and adjusted to meet the conditions for manufacturing on a large scale. In fact, in examining the operations of the factory one is impressed with the military-like organisation which everywhere prevails.

With the installation of the works at the new factory, the Company has undertaken the manufacture of a larger line of electrical apparatus than has heretofore been attempted. Every form and size of motor and generator for direct, alternating and polyphase currents, from $\frac{1}{8}$ to 5,000 H.P., are now being regularly manufactured. The arc and incandescent lamp business has been extended to meet every conceivable want in this direction. Detail apparatus such as fan motors, meters, current indicators, switches, lightning arresters, ground detectors, &c., have been perfected, and are being manufactured on the largest scale.

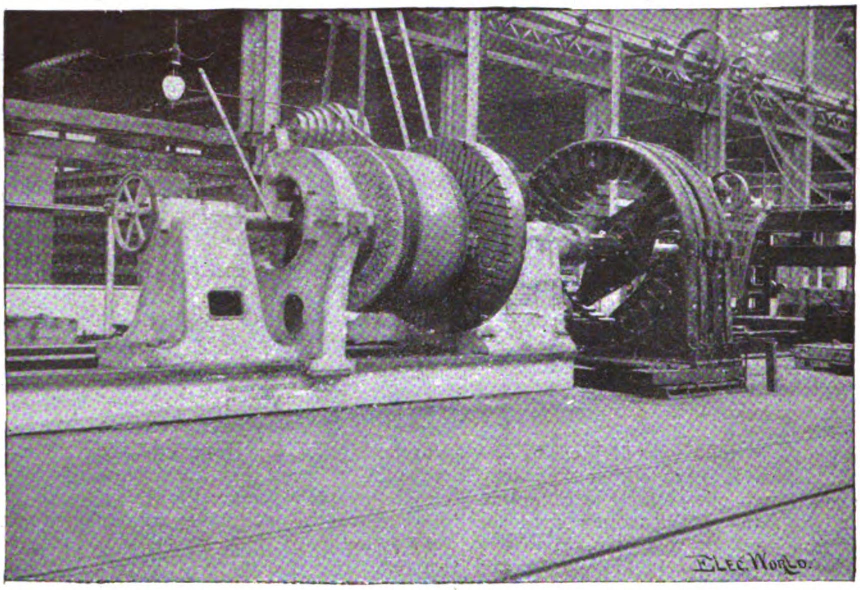

Fig. 2.—Boring a 1,000 H.P. Alternator Field and Turning a 1,050 H.P. Generator Armature.

ARNOUX-CHAUVIN VOLTMETERS AND AMMETERS.

A few months ago MM. R. Arnoux and R. Chauvin brought out in France some voltmeters and ammeters on the Deprez-d'Arsonval principle, and these instruments are now being made and sold by Messrs. H. M. Salmony and Co., of Charing Cross-road.

The moving part of these instruments consists of a small copper ring enclosing a silk-insulated copper coil, the enclosing ring being composed of two concentric strips of copper cut from an Elmore tube, the two ends of the silk-covered wire being connected respectively to the inner and outer copper strip. The idea of the copper strip is not only to give a certain degree of stiffness to the moving part, but to secure powerful electromagnetic damping. The copper ring is provided with two small steel pivots resting in jewelled bearings. Two spiral springs of non-magnetic metal bring the current to and take it away from the insulated coil, and develop at the same time the necessary opposing couple. The whole of the moving parts are encased in a flanged tube, which is shown in Fig. 1, with a portion cut away. Inside the copper ring, fixed by a brass projection to the enclosing tube, there is a steel bullet, the object of which is to concentrate the magnetic field. The magnetic field is obtained by means of a powerful tungsten-steel anchor-ring magnet, without pole-pieces. The inventors argue that pole-pieces not only increase the reluctance of the magnetic circuit, owing to the introduction of joints, but tend to give rise to stray field. The plain magnet, moreover, is cheaper and easier to make. The average magneto-motive force developed by the current traversing the coil and giving the maximum deflection of 90deg., is 1·8 ampere-turns. If we suppose this magneto-motive force to be uniformly ranged along the circuit of the magnet, the average length of which is 22cm., and to act as a demagnetising force, which in reality it only does when the pointer of the apparatus is near zero—that is to say, precisely when the current in the coil is at its weakest, the magnetising force under these conditions would be

$$H = \frac{4\pi n i}{10 \times 22} = \frac{4\pi \times 1\cdot 8}{220} = 0\cdot 1029\ ;$$

that is to say, the demagnetising force is about 400 times weaker than that necessary to reduce the residual magnetism of the permanent magnet to zero, and can only produce a variation of $\frac{1}{2000}$ in the value of this residual magnetism.

In the Arnoux-Chauvin voltmeters the moving coil has an average resistance of 75 ohms, and a current of 5 milliamperes is on the average sufficient to deflect the pointer through the whole length of the scale. In series with the moving coil there are, of course, resistances; for instance, the resistance of a voltmeter intended to measure up to 150 volts, with a deflecting current of 5 milliamperes, is 30,000 ohms, *i.e.*, 75 ohms of copper wire and 29,925 ohms of German silver wire outside the moving coil. It will thus be seen that the resistance of the copper wire of the moving coil is only $\frac{1}{400}$th of the total, so that the indications of the voltmeters are practically independent of temperature. These voltmeters are fitted with a reversing key, which enables them to be used if necessary as pole-finders.

In the ammeters the average resistance of the moving coil is 0 5 ohm, and an average current of 0·05 ampere is sufficient to deflect the pointer to the end of the scale. To measure larger currents than this 0 05 ampere the circuit of the moving coil is placed across the terminals of an appropriate shunt. These shunts as a rule consist of German silver strips 1mm. thick, carefully soldered at

Digitized by Google

either end to blocks of copper provided with suitable clamping jaws (*see* Fig. 2). The galvanometer is connected to these shunts by means of flexibles, the two ends of which are provided with conical plugs fitting into similar conical holes at the ends of the shunts and at the terminals of the ammeter. It is thus impossible to make use of connecting conductors other than those provided, thus avoiding the danger of introducing undue resistance into the ammeter circuit. The inventors point out that the use of shunts enables a single instrument to be made use of over a wide range. A further advantage also is that with such instruments powerful currents may be measured at a distance from the circuit in which they are flowing without the use of heavy, clumsy cables. Instead of adjusting each shunt to each ammeter, a system of interchangeable shunts has been devised. All the ammeters have a German silver resistance in series with the moving coil, the total resistance being regulated so that when the pointer receives its maximum deflection the difference of potential which exists between the two ends of the flexibles is exactly 0·04 volt. On the other hand, the resistance of each shunt between the conical

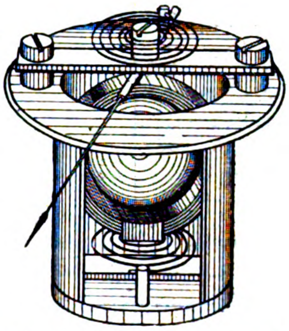

Fig. 1.—Working Parts of Arnoux-Chauvin Voltmeter.

plugs is made such that it is equal to 0·04 volt divided by the maximum current for which the shunt is intended, so that when the maximum current is passing through any shunt the difference of potential at its terminals is the same as that which gives the maximum deflection upon any ammeter. By this plan, when any shunt is connected to any ammeter, the value in amperes of the graduations of the instrument is arrived at by a simple calculation. For example, each division of an ammeter scale which is divided into 150 divisions corresponds to 4 amperes when the instrument is employed with a shunt stamped 600 amperes.

Another feature of the Arnoux-Chauvin voltmeters and ammeters, due to the powerful magnetic field in which the moving coil is

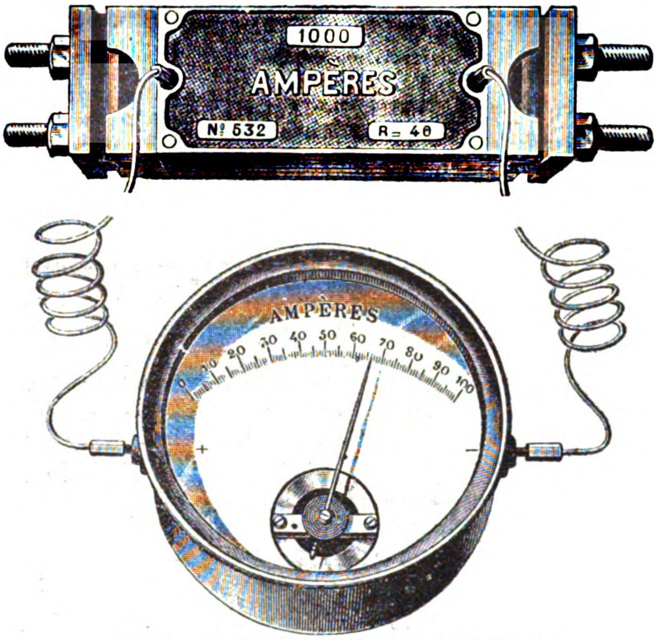

Fig. 2.—Arnoux-Chauvin Ammeter and Shunt.

placed, is that they are but very slightly affected by powerful currents in their neighbourhood. Thus a voltmeter when in circuit was placed against a cable through which 200 amperes were flowing, and the needle was not deflected more than $\frac{1}{10}$th millimetre on a scale 100mm. long, when the 200 ampere current was made and broken.

PRESENTATION TO MR W. S. ANDREWS.

As briefly mentioned in our last issue, the staff of the Indo-European Telegraph Company recently presented to Mr. Andrews, the Managing Director, a beautiful silver casket, to celebrate the twenty-fifth anniversary of the day when he assumed the direction of the Indo-European Company's affairs. During his long connection with the Company, Mr. Andrews has rendered great and valuable services to the proprietors in bringing the different departments of the service to an exceptionally high degree of efficiency; he has consolidated the various interests of the Company, and has thus brought it to its present high financial position. Whilst looking carefully and minutely after the interests of the Company, Mr. Andrews has always studied the wants and requirements of the public and the Press so far as compatible with the obligations of his Company under the International Telegraph Convention, and towards the various telegraph administrations in connection with whom the Indo-European line is working. The illustration shows a front view of the casket, all sides of which are engraved with apposite subjects.

THE ANNUAL GENERAL MEETING OF THE TRAMWAYS INSTITUTE.

The keynote to the Annual General Meeting of the Tramways Institute, which was held last week, was given by a single sentence of the re-elected President's address. "It does not appear that anything new in the way of traction has been introduced." From the practical point of view this sums up the whole matter. But Mr. CARRUTHERS-WAIN in the course of his address dealt ably with the position in its legal and commercial aspects. He showed that since November last, when the Institute authorised him to bring under the notice of the Board of Trade "how much means of communication might be fostered and extended if the tramway companies were allowed fair play," that a favourable impression had been made on that all-powerful Government Department, and that the Board of Trade was now prepared to give favourable consideration to the important question of tramway traction. The Council of the Institute, he further added, had acted as a brake upon all efforts at legislation "which could have no result other than that of stopping all enterprise."

In common with most other speakers, Mr. CARRUTHERS-WAIN made out a strong case against the acquirement of the tramways by municipalities, and quoted Glasgow, Huddersfield, Plymouth and Leeds to prove that in no case had a municipal authority succeeded in making real profit. "They were all," he said, "working at a dead loss." It was true that the Glasgow Corporation claimed to have made a profit and to have paid it into a "common good" fund. The profit, however, was visionary. No President of the Tramways Institute is indeed likely to be in favour of municipalisation, but there is no gainsaying that so far municipal authorities have failed to show their capacity for dealing with tramway work, although

Digitized by Google

they have the advantage of borrowing money at a cheap rate. Electrical engineers, moreover, have to remember that electric traction in this country needs every possible help. Local authorities have never been pioneers, and they are not likely to prove so in the matter of electric traction, although they will no doubt be quite willing years hence to take it up when private capitalists have shown them the way. It is to private enterprise that we owe the vast majority of our great public improvements from the New River Water Company to Central Electric Light and Power Companies, and such electric traction as we have is due to the same source.

Turning to practical matters, we notice that the usual new accumulator was on the *tapis*. We have no practical acquaintance with the I.E.S. storage battery, and such appears to have been the case with Mr. Scott Russell. Mr. Percy Sellon, however, says that the battery compares with the E.P.S. and the Epstein batteries, and "commends itself to every practical man." But as no tests have been made with these plates for traction purposes, it is evident that this is a pious opinion. The output for a given weight claimed by the makers is very high—at least twice as great as that ordinarily obtained, if we understand the figures rightly. Additional interest is given to this battery because Mr. William Neale, the Chairman of the Birmingham Central Tramways Company, expressed his intention to permit Mr. New to try it as soon as arrangements could be made. An admission of this gentleman in connection with the Birmingham line is not encouraging for the future of self-contained electric cars. His Company, he said, "had a good system of accumulators. Unfortunately that method had proved a great loss, not because of any inherent defect in the system, but probably because it was a suburban line and there was not a great deal of traffic for it to deal with." We should have thought that this was exactly the line on which accumulator cars would show to the best advantage. If they cannot pay here we fear there will have to be something like a revolutionary change in batteries before the self-contained car is a commercial reality.

Mr. George Cawley's Paper on the Thwaite-Cawley conduit system was received with some distrust. At a first glance it certainly seems a doubtful procedure to place the motor in a culvert with a slotted rail above it. The dummy has also many objections, although its use is apparently only necessary when ordinary horse cars are used as trailers. If the rolling stock were designed specially for the work no doubt the car under-carriages would be made sufficiently strong to bear the strain of the connecting bar and the gear appertaining to it. The scheme is of course only intended for use in towns, and possibly as an adjunct to a conduit line. We agree with several of the speakers that it is mere waste of time to discuss proposals of such a radical character before they have been put to the test of practice.

Reviewing the proceedings of the meeting we cannot find that anything of practical importance was elicited. That a certain amount of discussion should precede the actual application of an engineering innovation, is of course, to be expected and indeed to be desired, except possibly in America, where they apparently prefer the immediate adoption of novelties *nemine contradicente*, and to discover defects in practical operation. At the same time we must own to a feeling of weariness at the everlasting talk about electric tramway traction in this country and at the very little progress made.

It is now some six or seven years since electric tramway traction first began to get a firm hold in the United States, and to-day our American friends revel in tremendous totals of cars, horse-power, and motors. In England, on the other hand, the mileage of our *bonâ fide* electric street tramways approximates to the exceedingly modest figure of ten. We can certainly console ourselves with the progress made in underground and overhead electric railways, but this is likely to remain a restricted field, and it is upon the extensive application of electricity to ordinary street tramways that the future of electric traction in this country must mainly depend.

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(*Continued from page 301.*)

Capacity Tests (*continued*).—The mixed-charge test is made with the slides, as in Fig. 135. The condenser and cable are shown connected respectively to two levers, which when at rest make contact with the upper studs, so connecting the condenser and cable together. When the levers are put into contact with the lower pair of studs (by pressing down K) the condenser is connected to one end of the slides and the cable to the other. As the opposite surfaces of the condenser and cable and the movable contact of the slides are to earth,

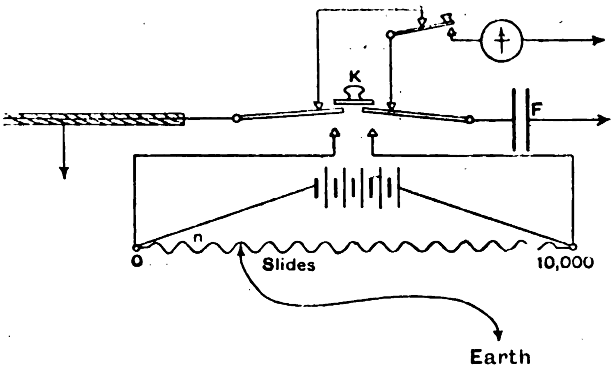

Fig. 135.—Mixed Charge Test.

it follows that when the levers touch the lower studs the cable and condenser are charged at potentials depending upon the position of the slides. After charging, the key K is released, so connecting the cable and condenser. If the charges received by each have been equal they will mix and neutralise each other, and the galvanometer will show no deflection on closing the key connected to it. If any deflection is noticed the slide contacts are shifted until a point is found at which the condenser and cable receive equal charges, as proved by their completely neutralising each other and leaving no residual charge which can affect the galvanometer.

The charges being equal, it follows that the respective capacities are inversely proportional to the respective differences of potential acting on each. The difference of potential acting on the cable and condenser respectively are in the proportion of the slide reading n to $10,000 - n$. Therefore the capacity of the cable is equal to

$$F\left(\frac{10,000 - n}{n}\right) \text{ microfarads,}$$

where F is the capacity of the standard condenser.

Lambert's key for this test is illustrated in Fig. 136. Both levers are pressed down at once by the insulated knob A for "charge," and on releasing A the cable and condenser are connected through the bar B and the charges mixed. The galvanometer is afterwards put in circuit by the small key shown, which connects the galvanometer with the bar B. This key is arranged to put only the condenser in circuit with the

* Copyright. All rights reserved.

Digitized by Google

galvanometer, as shown in Fig. 135, in order that the more prolonged discharge from the cable due to its greater absorption may not appear on the galvanometer and affect the conditions of balance.

The "Silvertown" mixing key, designed by Mr. W. A. Price, is illustrated in Figs. 137 and 138. Two contact blades *a* and *b* are rigidly connected at their fulcrum by an insulated bar. A handle is attached to the bar, by means of which the blades can be moved up or down. The blades are connected respectively to the cable and condenser. The insulated handle is raised to "charge," which moves the contact blades downwards, making rubbing contact with the two outside blocks *c* and *d* connected to the slides. For mixing, the handle is pushed down, when the contact blades are raised and touch the middle block *e*, thus connecting the cable and condenser. A small key is provided for putting the galvanometer in circuit.

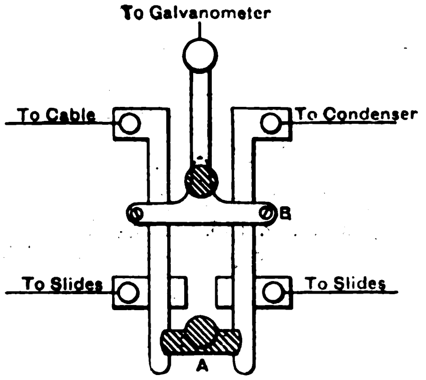

Fig. 136.—Lambert's Key.

In Gott's test the cable and standard condenser are connected to the slides, as in Fig. 139. The battery having been connected to the slides, the charge key is closed and balance obtained by adjusting the slides and tapping galvanometer key until a position is found (say *n* divisions from slide zero) at which the galvanometer is unaffected. The condenser and cable are then, as in the last test, charged with equal quantities, and we have, as before, the capacity of the cable equal to

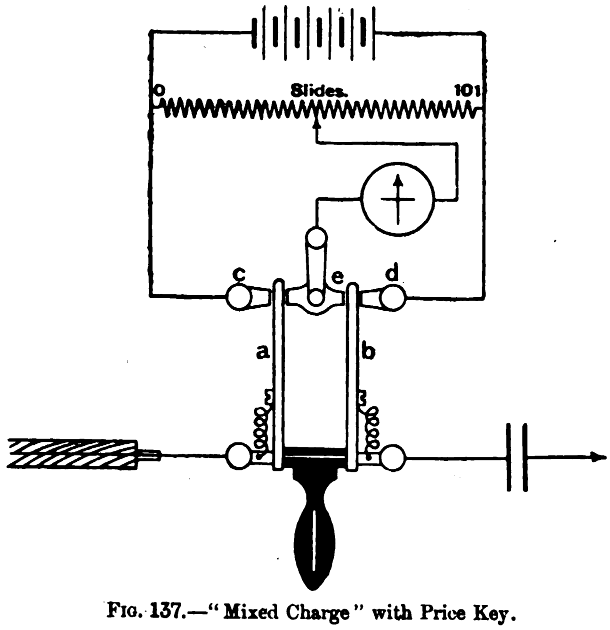

Fig. 137.—"Mixed Charge" with Price Key.

$$F\left(\frac{10{,}000 - n}{n}\right) \text{ microfarads,}$$

where F is the capacity of the condenser.

Dr. Alexander Muirhead has shown in *The Electrician*, Sept. 5, 1890, page 487) that the above formula is correct only when the balance has been obtained immediately after "charge" and before the difference in the absorption of the cable and condenser has had time to take effect. If there is delay in obtaining balance or reading on the slides, more charge will be absorbed, the potential V at the junction of cable and condenser will vary, and the apparent capacity of the cable will be increased. A certain time must, however, be allowed for the cable to charge, and Dr. Muirhead's correction overcomes the obvious difficulty of balancing to exactly the necessary time, as it is applicable to any period of charge. The test, with the additional observation for making the correction, is best made with the key designed by Mr. H. A. C. Saunders, Electrician-in-Chief of the Eastern Telegraph Company. It will be seen by the illustration (Fig. 140)

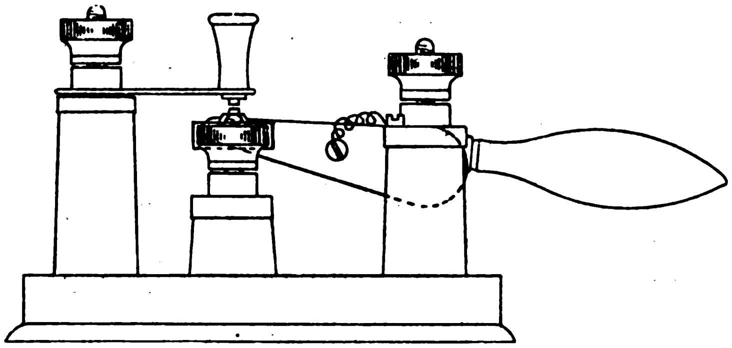

Fig. 138.—Price's Mixing Key.

that this key has two levers with two separate back stops and two front stops. The connections are as in Fig. 141. When the right-hand key is put down the condenser and cable are charged from the 10,000 end of the slides. The galvanometer key is then tapped and the slides adjusted until there is no deflection. The left-hand or discharge key is then put down, this action automatically lifting at the same instant the right-hand key. This is effected by a small ebonite rocking bar pivoted centrally underneath the levers, and shown in the illustration. This bar prevents both keys being down at the same time, which would cause a large discharge through the galvanometer, and upset the test. Its action in the test is to raise the right-hand or charge key at the same moment as the left-hand or discharge key is put down.

The charge key, when raised, puts the condenser to earth, and discharges both cable and condenser, but the point V (between cable and condenser) has still a potential above the earth, owing to the oozing out of the charge which has been absorbed by the dielectrics. It is this potential which produces a discharge deflection (hereafter called the absorption discharge

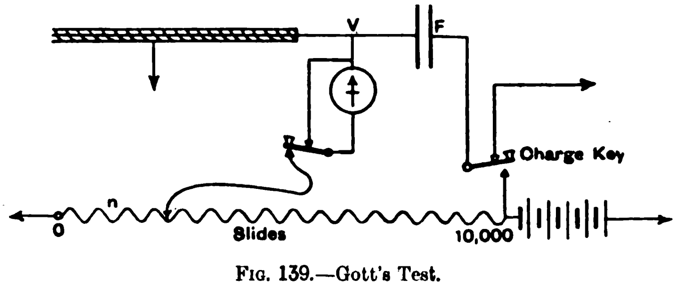

Fig. 139.—Gott's Test.

through the galvanometer to earth when the left-hand or discharge key is put down. The action, therefore, of pressing down the left key, and so raising the right key automatically at the same moment, is to obtain the absorption discharge immediately after the condenser has been put to earth. Dr Muirhead states that if the absorption discharge is not measured at once, before the oozing out of the charge absorbed by the dielectrics begins, it will slowly change and a wrong value be obtained—in other words, that the earthing period, or time allowed to elapse between the moment of putting the condenser to earth and the moment of reading the absorption discharge, should be nil, or as small as possible. On the other hand, Mr. Arthur Dearlove, in an able Paper on this test

Digitized by Google

and its correction (*The Electrician*, March 6, 1891, p. 537) as applied to long cables, recommends an earthing period of three to four seconds for cables of from 1,000 to 1,500 knots length before taking the absorption discharge.

It only remains to put the absorption discharge (d) in terms of the slides in order to apply the correction to the slide reading n. This is done by running back the index of the slides nearly

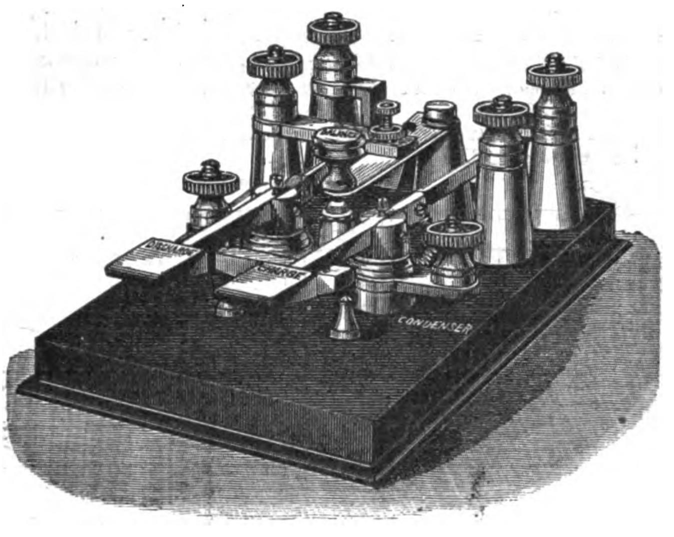

Fig. 140.—The Saunders Key.

to zero (the earthed end) and closing galvanometer key. The discharge lever of the Saunders key being still down, we have a deflection due to the potential difference between the index of slides and earth. The index is moved until this deflection is equal to the absorption discharge, the slide reading then observed being, say, p divisions. It is not necessary to repeat the deflection exactly. For instance, supposing we obtain a

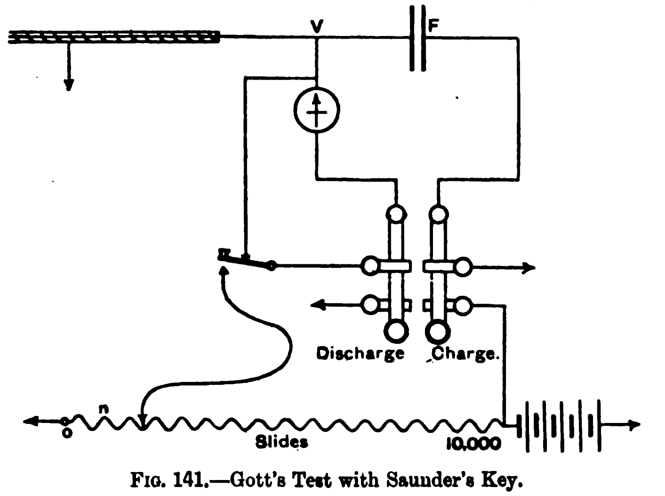

Fig. 141.—Gott's Test with Saunder's Key.

deflection d_1 with slides index at p_1, then the correct slide reading equivalent to the absorption discharge is

$$p_1 \frac{d}{d_1} \text{ divisions.}$$

If the deflection produced by the slides is *opposite* in direction to that of the absorption discharge, the slide reading p must be subtracted from the first slide reading n; if in the *same* direction it must be added.

The formula, with correction added, may therefore be stated as

$$\text{Capacity of cable} = \text{F}\left(\frac{10{,}000}{n \mp p} - 1\right) \text{ microfarads.}$$

Dr. Muirhead's article in *The Electrician*, above referred to, should be consulted for a further study of the subject.

(*To be continued.*)

THE HILL LONG-DISTANCE SUBMARINE CABLE SWITCH.

In working recorder on long cables it is found that sending through condensers, as well as receiving through them, improves the signals. It does not follow, however, that the same capacity which is used for sending through gives the best results when in the receiving circuit. At the Eastern Extension Company's Hong Kong station it is found that in working direct with Singapore, through a cable of about 2,000 knots, the best results are obtained when sending through 80 microfarads,

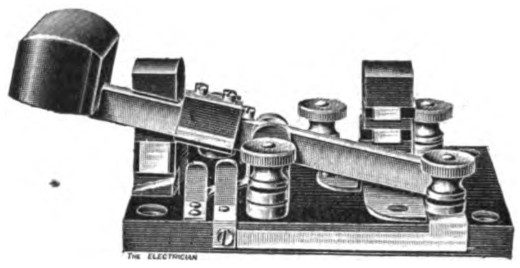

Fig. 1.—General View of Switch.

and receiving through 40. Now the ordinary recorder switch does not readily allow of connecting up in this way, and to avoid using separate condensers for sending and receiving (necessitating 120 microfarads in all), Mr. Alexander Hill, of the Eastern Extension Company, devised the following arrangement:—

The switch shown in Fig. 1 is the ordinary tumbler one in general use at cable stations, with two additional contacts which connect all the condensers together when the switch is to

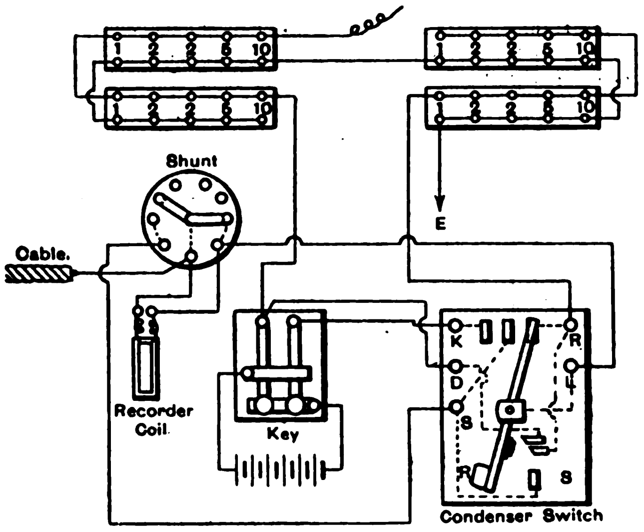

Fig. 2.—Diagram of Connections of Switch.

"send," but leave either the same or a prearranged number in circuit when the switch is to "receive." This is accomplished by the insulated piece of brass, carried by the lever, connecting the two springs connected to terminals D and R (Fig. 2). To prevent a sudden kick to the coil when the lever is moved, the middle back contact (usually connected to terminal D) is now connected permanently to the sending shunt terminal.

SOME WORK ON MAGNETIC HYSTERESIS.*

BY FRANK HOLDEN.

Having read the description of Prof. Ewing's latest apparatus for determining the hysteresis loss in sheet iron, it seemed that an account of work done some time ago in very much the same direction would be of interest.

During the last few weeks of the year 1892 there was built at the works of the General Electric Company, in Lynn, Mass., under

* *Electrical World* of New York of June 15, 1895. Two illustrations of the hysteresis meter have been omitted.

Digitized by Google

methods of traction were concerned, he had found no system equal to steam, the use of which he originated in Leeds.

Mr. W. MASON, Director of the Bradford Tramways Company, referring to the municipal working of the Leeds tramways, said that he had seen a report for a period of 14 months' operation. The Corporation, he remarked, obtained their money at 3 per cent., had worked the lines for 14 months, and over and above what they had to pay for interest they had earned £56 ; and at the same time this result was on a capital which was only half that of the Company.

Mr. J. PLATT, of Southport, said that in that town horses were better than engines. That was due to the fact that if they had six horses, and if, during any part of the day, there was a rush of traffic, they could turn out three cars with those six horses, but they could not do so with one steam engine.

Mr. SCOTT RUSSELL remarked that it appeared that Mr. Laws, in setting about his report, started with the idea of making it in favour of the cable system, and that he prepared it with that object. If Mr. Laws had reported favourably on the cable system as being suited more to the requirements of Newcastle, no one could have said anything ; but the speaker submitted that the author seemed to have given himself the mission to find out what was the best system for all purposes, and that he had picked all the holes he could in all systems except the cable. It was unnecessary for the speaker to say anything of the underground conduit system, although Mr. Siemens had entirely demolished the arguments against it. Mr. Siemens had said that the slot system could be made $\frac{1}{2}$in. wide if necessary. Well, that was narrow, and was even narrower than was demanded by the Board of Trade. In connection with the series system at Northfleet, the slot was $\frac{5}{8}$in. wide, and no difficulty was experienced in regard to the width of the slot during the period of working for one or two years. There was not the slightest doubt that the conduit system could be worked with a slot of $\frac{5}{8}$in. or $\frac{3}{4}$in., which he thought would be the limit allowed by the Board of Trade. He thought the slot system would be likely to have a good future for it in this country.

Mr. PERCY SELLON thought that Mr. Laws had been misled in many directions which he would not have been if he had proceeded to the proper source to obtain his information. Many details which the author of that report had required of the Buda Pesth line had been furnished to him by Mr. Colam, whose views appeared throughout the greater part of the report. For instance, in March, 1892, in a discussion before the Society of Engineers, Mr. Colam had suggested that in time the wheels of the car would slip into the slot ; those words were repeated in Mr. Laws' report. The speaker stated, however, that no instance had been given, even in the case of the wide slot at Buda Pesth, of a car wheel dropping into the conduit. Perhaps the circumstances of Mr. Laws' report had led him to make one or two misstatements. Let them take the statement that the cable was the only thing of use in Newcastle on account of the narrow streets. The cable system, the speaker submitted, was not a proper method for the crowded and narrow streets, as at Newcastle. The electric car had an infinitely better governing capacity than that of the travelling cable, for the reason that the driver could not stop the car in the same regular fashion in the latter case as he could when using electricity. He could not see how the point was made that it was more dangerous to use an electric car on the slot or conduit system than the cable with its slotted conduit. The amount required for the installation and cable equipment as suggested by Mr. Laws would be so great as to absolutely prevent any profits accruing through the adoption of the system at Newcastle, for the reason that the cable could only be introduced in certain cases ; whereas in other streets outside the congested area a different method would have to be adopted. He suggested, therefore, that Mr. Laws' report could not commend itself to the consideration of tramway people.

Mr. WILLIAM TURTON, rising in connection with the Newcastle tramways, said that he had worked them with horses at a good profit for 16 years. It seemed that Mr. Laws thought the cable system would be more profitable, and he had therefore to make out the best case possible ; that he had done with help from London. The speaker was quite sure that the cable system would not do so well for Newcastle, as there was not enough traffic for it. If he had been permitted in Newcastle to have proceeded with the introduction of steam cars, he thought there was nothing could have equalled them.

Mr. WILLIAM NEALE, Chairman of the Birmingham Central Tramways Company, said that he represented a company which had steam, horse and electric cars and the finest cable line yet laid down. He differed from the opinions which had been expressed in connection with steam engines. His Company, which had three steam lines, would be glad to turn off every steam car and substitute the cable system. The use of the latter method did not necessitate the employment of so large a number of men as was the case with steam cars, and the only drawback to the system was that if anything went wrong the whole line was brought to a standstill until the repairs had been executed. In regard to the electric tramway, the Company had a very good system of accumulators. Unfortunately that method had proved a great loss—not because of any inherent defect in the system, but probably because it was a suburban line and there was not a great deal of traffic for it to deal with. Although speaking in favour of the cable system, that method would not do for the Bristol road line, because there was not sufficient traffic to pay for the initial cost of putting down the cable system. He quite agreed that the accumulator system had a great future before it, and with a reduction in the weight of the batteries he believed that method would run the cable very hard. The Company's horse lines were a loss every year, and if the Corporation would give permission, the horse cars would be withdrawn.

Mr. A. DICKINSON said that if they could run steam locomotives on the roads without the restrictions of the Board of Trade, he would agree that the method was as cheap as with electricity. But it was the difficulties introduced by the Board of Trade in the direction of regulation of speed, governing and the destruction of the steam by condensers which militated against that object. In Birmingham steam cost about 7d. a car mile and cable 4d.

The Thwaite-Cawley Conduit System.

Mr. GEORGE CAWLEY next read a lengthy Paper on the "Thwaite-Cawley System of Electric Haulage." In bringing forward this method, the author said he would submit a general outline of the system, leaving the arrangement of the details for any particular line to be subsequently determined. Bearing in mind the opposition on the part of local authorities to the trolley system for urban traffic and the large dead weight and high working cost of accumulator cars, the author submitted that some form of conduit system was likely to be adopted for town traffic in this country. The special feature of the system lies in the transfer of the electric motors from the car to the conduit, with the result of obviating the necessity of using heavier rails and stronger and heavier cars. The accompanying figure, which is a cross-section of the culvert and rail bed, and shows the hauling locomotive in position upon the culvert rails, gives a good idea of the method proposed. In the system in view a dummy is employed driven by the flat bar shown passing upwards through the slot, and affixed to the hauling locomotive in the culvert, and by a short link or connecting piece to the ordinary spring draw-bar of the tramcar. The dummy is equipped with the switches, rheostat and other controlling apparatus for regulating the locomotive running below it in the culvert, together with a hand-brake lever and spindle for stopping the car. The passage of the current to and from the dummy is effected by means of insulated flat copper strips embedded in the driving bar passing through the slot. The culvert represented in the figure is 2ft. 9in. wide and 2ft. 6in. high. Thus the culvert is sufficiently large for a man to get along it for examination and repairs. The culvert may be constructed with the floor and sides either of brickwork or concrete or of metal. As shown in the illustration, it is intended to be made of either wrought iron or steel. The width of the slot is $\frac{5}{8}$in., and the driving bar is $\frac{9}{16}$in. in thickness. The two girders forming the slot are kept equidistant and rigid by means of tie bolts connected to the webs of the tram rails, and also by angles riveted to the culvert plates and embedded in the concrete forming the culvert foundation. It will be seen from the cross-section that longitudinal wooden sleepers rest upon the floor of the culvert, to the sides of which they are bolted. Along the sloped roof of the culvert are placed at suitable intervals notched supports for carrying insulated feeders. The return portion of the circuit can be formed by an insulated conductor, with feeders similar to the conductor carrying the current from the generators to the motors. As will be observed, these conductors are made of a dovetailed section of channel iron. The conductors are held in position by means of porcelain insulators bolted to the roof of the culvert. Each rigid length of conductor is separated by an arranged distance from the adjoining rigid lengths, but is electrically connected by bow-shaped strips of copper. The E.M.F. proposed to be used is 500 volts. The current at this pressure can be conveyed to and from the motors by a pair of trolley wheels or by a single trolley wheel—where the return circuit is made by the rails—running along the conductors and kept in contact by means of a spring. The circuit connection between the culvert conductors and the motors can, however, be made by means of a slider or tongue-piece arranged to slide along the conductor. To the upper part of the hauling locomotive is attached a lever which carries a pair of wheels running against the lower flange of the slot girders. These wheels press upwards on their rail bed with a force in some arranged degree proportional to the tractive effort required to haul the car. Consequently when starting the car, or when the latter is ascending a gradient, a considerable downward force is thrown upon the locomotive wheels in addition to that due to gravity, and their tractive capacity is thereby increased. In order that this downward force may be maintained within safe limits, the fulcrum of the lever carrying the upper pair of wheels is made to rest upon a kind of spring buffer head which yields when a pre-arranged load is put upon the wheels ; and in that way any undue strain on the lever or culvert is prevented. A reference to the figure will show that the upper surface of the rails within the culvert is some distance above the bottom of the culvert. This arrangement allows of the hauling locomotive to be partly located below the rail level, and smaller driving wheels can, therefore, be employed than when the motor armatures are mounted upon the car axles, as is usually the case when gearless motors are used. The adoption of small driving wheels of this kind allows the motors to run at a higher speed, and to give a greater commercial efficiency than would be conveniently possible with a gearless motor fitted to the car axles in the usual manner. The wheels shown are slightly under 8in. in diameter. This size of driving wheel, when the car travels at a speed of eight miles an hour, enables the motors to run at not less than 352 revolutions, and at 12 miles an hour, 528 revolutions per minute, a speed which may be considered satisfactory for a direct connected motor. As regards the approximate cost of construction, if the making of the line is not materially interfered with by buried pipes, this comes out at about £12,000 per mile of single line complete, including paving, tramway rails, and the concrete bed, half of this sum being for the culvert proper. This estimate does, of course, not include the construction of the hauling locomotives. If it be desired, the dummy cars may be left out of consideration, and the controlling and brake regulating apparatus can be erected on the passenger car.

The I.E.S. Battery.

Mr. ANTHONY G. NEW then presented a Paper on "The I.E.S. Storage Battery for Lighting and Traction." In this particular type of plate the conductor, the author pointed out, was formed of lead shaped into a grid somewhat like a comb. The active material being laid on, the plate is then slipped into a perforated envelope of celluloid, which it fits closely. The plate is then ready for use, and after its first formation

Digitized by Google

by charging it becomes a solid and compact plate, capable, however, of free expansion and contraction. As far as the lighting of tramcars is concerned, some figures are forthcoming of the annual cost of illuminating the cars recently equipped on this system for the North Staffordshire Tramway Company. The battery in this case weighs 54lb. for each car, and has a capacity of 40 amperes at 16 volts. The charging current for each battery charge is 800 watt-hours, or 1·072 E.H.P. hours. If the actual cost of generation is considered as 2d. per electrical horse-power, this represents a cost of 2·144d. When fully charged, the battery is capable of lighting one lamp of 5 c.p., two of 3½ c.p. and two of 2½ c.p. for 11½ hours, giving for that period a total light of 17 c.p. The cost per car hour is 0·1861d., and assuming 2,000 working hours per annum, the yearly cost for current is £1. 11s. per car. Under the present arrangement the tramway company hires the equipment at the rate of 2s. 6d. weekly per car. This means an annual addition of £6. 10s. per car, and including interest on the capital expenditure for plant and fittings at 5 per cent., the yearly cost works out at £8. 14s. 9d. per car. If, however, the company was to purchase the car equipments the total annual cost, after allowing 10 per cent. for depreciation and 5 per cent. interest on the extra outlay, would only be £3. 11s. 9d., as compared with £8. 14s. 9d. The author then gave estimates of the cost of battery traction.

The PRESIDENT, in reply to Mr. Scott Russell, said that the directors of the Birmingham Central Tramways Company intended to make a trial of the I. E. S. batteries, but that owing to the unfortunate accident which resulted in the burning down of the generating station they had not yet been able to place Mr. New in a position to demonstrate the capabilities of that type of battery. The Chairman of the Company was, however, willing to permit the projected experiments to be carried out as soon as possible.

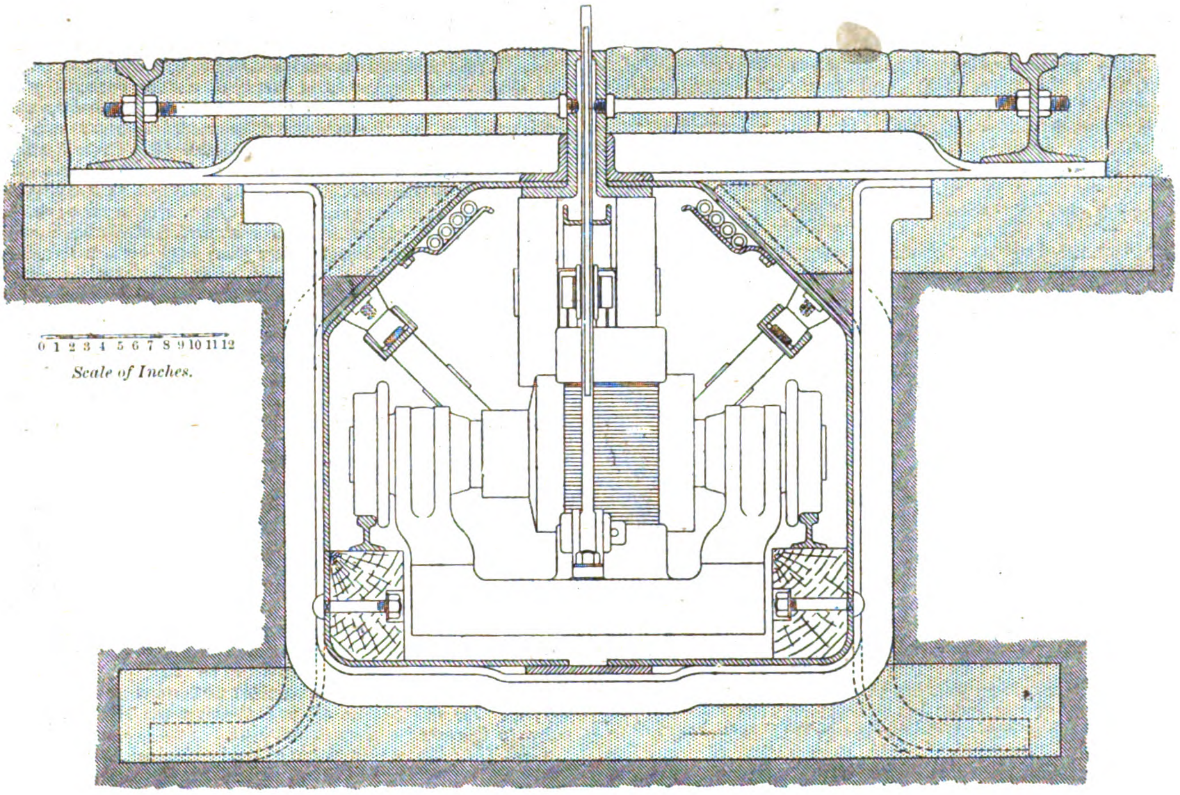
Mr. SCOTT RUSSELL submitted that as the batteries had not been tried in practical work the figures as to working costs were of no practical value. As far, however, as he understood the Paper, it was claimed that three times the electrical output was obtained as compared with other batteries. If that could be accomplished it would be an immense step in advance. He did not know that they could criticise it; the only thing they could say was that the promoters had not done it. With reference to the Thwaite-Cawley system, he failed to see any advantages beyond what they had already. It appeared to him that a conduit of that size must be more expensive than that at Buda Pesth or similar conduits. The fact of having all the working plant underground, where it might be affected by dust, dirt and water, &c., would be a great objection to the method. He failed altogether to see the advantage of the trolley in front. He thought all engineers had agreed in abandoning it. The advantage had been put forward of utilising existing cars, but he opined that anyone who had seriously attacked the problem would consider it better to start with a new and satisfactory plant throughout.

Mr. PERCY SELLON remarked that he had the same difficulty as the previous speaker in criticising any proposed new method of traction which had not received a distinct trial. The author wanted them to fall in with the suggestion that instead of having the motors on the car they should place them underground in a channel, dragging the car, similar to the traction adopted in the cable system. He had great difficulty in seeing where the advantages claimed for the system could possibly be. It had not been tried, but it might be they would see it put down and at work. As to the proposed use of gearless motors, as the conduit was very confined, he was afraid the author would have some difficulty in placing such a motor of sufficient power within those limited dimensions. It seemed to him that the Paper had not been put forward in a manner worthy of commendation. The systems brought before them should have money spent upon them and be shown in operation, so that a practical man could judge for himself what their likelihood of success would be. With regard to Mr. New's Paper, they were offered a battery which compared with the E P S. and Epstein accumulator, and which commended itself to every practical man. He hoped to see the batteries introduced on some line.

Mr. A. NEW said that only the latter portion of his Paper dealt with traction. The figures given in regard to lighting from the batteries could be taken as correct, and that particular type of cell was the accumulator which should be used. With reference to the Thwaite-Cawley system, he would like to know how the conductors were carried up from the motors so as to be controlled by the man on the car.

Mr. G. CAWLEY, in reply to the discussion, said that one of the advantages of the system was that the car was taken as it was, and it was not required to place the motors on the car. The method was not put forward as against the overhead system; it was submitted as a possible something which might be taken up in connection with the conduit system. As to the question of a sufficiently powerful motor, the cross-section showed that as the rails stood above the culvert bottom they could have any depth below the armature spindle which was thought proper. One advantage of putting the rails in the culvert was that they could carry the motor down below the rail level, and in that way they could get small wheels and have a large and powerful motor. He thought the culvert could be kept free from dust. Any dirt or dust falling through the slot fell into a shoot and dropped down towards the end of the motor. Concerning the means of conveying the current from the dummy down to the motors, a double slot was made in the bar, with two strips, along which the current passed up to be regulated and down again to the motor. The system was advanced as applicable for towns, but was not intended for use outside towns.

A vote of thanks to the President concluded the proceedings.



Cross-section of Thwaite-Cawley Conduit.

PARLIAMENTARY INTELLIGENCE.

THE STRAND DISTRICT ELECTRIC LIGHTING ORDER CONFIRMATION BILL.

Last week, before a Select Committee of the House of Lords, presided over by Lord Camperdown, the Strand District Provisional Order Confirmation Bill was dealt with, the promoters being the Charing Cross and Strand Electricity Supply Corporation, and the opponents the Metropolitan Electric Supply Company. Mr. Pember, Q.C., and Mr. Claude Baggallay appeared as counsel for the promoters; and Mr. Cripps, Q.C., and Mr. J. D. Fitzgerald represented the Metropolitan Company.

Mr. PEMBER, in opening the case for the promoters on Monday, said that the proposal before the Committee was to confirm a Provisional Order issued by the Board of Trade to supply electricity within the district of the Strand Board of Works, which was at present supplied by the Metropolitan Company, and which had the monopoly of supply by the alternating current with very high tension. The Charing Cross Company was one of the numerous companies which supplied with direct current and at low tension. He detailed the steps which had been taken to obtain the consent of the Board of Works and the Board of Trade to the Order, and said that the objection of the Metropolitan Company, who were monopolists and were the only petitioners against the Order, was obviously unreasonable. A large number of the inhabitants and most of the important consumers of electricity in the district had petitioned in favour of the Order, as they thought that the price, quality, and quantity of supply, and the general efficiency of the electric supply in the Strand district, would be favourably influenced by the competition. Up to the present time he believed no satisfactory motor for the use of electricity supplied by alternating currents had yet been invented, and for motive power they must have the direct current at a low tension. The whole question of electric supply had been settled on the basis of competition as recommended by Major Marindin, who held the inquiry in 1889, and who thought the competition should be limited to two companies in one and the same district; but he particularly emphasised that the one company should supply by the alternating current and the other by direct current. Dealing with the petition of the Metropolitan Company, which stated that they were prepared to supply the district on both systems, he said that if they were to supply some people on the direct current and some upon the alternating they must have duplicate sets of mains, which must be carefully isolated the one from the other, which would entail extra cost and inconvenience.

Mr. SEALE, the Secretary and General Manager of the Charing Cross Company, was then examined in support of the Order, and, after giving financial details of the Company and the cost of the supply, said it was an advantage that there should be competition in the district. Apart from the question of price, in the case of a breakdown of one Company's system the consumers would be able to resort to the other Company. It was their practice to exchange with other companies, and in the case of the London County Council the London Company and themselves were jointly supplying a change-over switching apparatus to enable them to have the light from one or other of the Companies in the event of the failure of either.

In cross-examination by Mr. Cripps, the WITNESS stated that his Company did not belong to the Messrs. Gatti. Over the last 18 months or two years the Company had had nine or ten applications for motive power for the purpose of driving printing and other machines. They were also required to supply motive power to the National Telephone Company and the Electrophone Company for the purpose of their batteries.

Mr. CRIPPS: Do you know whether the Metropolitan Company have got continuous currents, and are prepared to supply motive power whenever required?

The WITNESS said that he believed they had a continuous-current station, but he did not know that they supplied much from it, and he believed the mains did not extend very far.

Mr. W. T. MADGE, of the *Globe* and *People* newspapers, stated that application had been made to the Metropolitan Company for motive power for driving the Linotype composing machines, but they had not been able to obtain it. He was advised that they could not use the alternating current for such a purpose.

Mr. A. H. VESEY, electrical engineer and consulting engineer to the *Graphic*, *Illustrated London News*, and other newspapers, said that he had been consulted with regard to the running of plant by electricity, and had applied, at the request of some of the proprietors of pap rs, to the Metropolitan Company, with a view of working the plant by electricity. The Metropolitan Company told him they could supply him with currents, but the mere fact of their being able to do so was not satisfactory to him because he could not run an alternating motor economically. They did not offer to give any other supply than the alternating current, and he advised his clients not to put an alternating motor in as he knew it would not be satisfactory. The alternating current was not suited for running machinery, because, in his opinion, the motor would only work efficiently at full load; it could not start by itself, and if they took off any of the load the motor was going ahead all the same, but they were then spending money and getting no benefit from it. He advised his clients that the Metropolitan Company's system was not suitable either practically or commercially. For arc lighting he preferred the direct-current to the alternating system, but he admitted that there was a great variance of opinion on that point.

In cross-examination by Mr. Cripps, the WITNESS stated that he had put up a great many installations all over England, but none with the alternating current. He had seen alternating currents in action and carried out experiments with them, so that he was able to say it was a practical fact that they were only efficient for full loads.

Mr. CRIPPS asked the Witness on what scientific fact he based his opinion that alternating motors were only efficient when they had a full load. He was told that that was nonsense from an electrical engineering point of view.

The WITNESS said that from a practical point of view it had been tried and found not to be economical. He had not been in charge of such motive power himself but he had heard so from other people. In the case of some motors for driving electric pianos at Hatton-garden they would not work satisfactorily because they could not control them.

Mr. CRIPPS: Has there been any case where you have really been in control or where you yourself have had experience of any substantial amount of motive power supplied by the alternating-current system?

The WITNESS: No. He admitted that he had years ago applied to join the staff of the Metropolitan Company, but he did not then know of the conditions of their supply by alternating currents, as they had not then started. He was not refused on the ground that he had not sufficient knowledge of electrical matters, but he himself refused on account of the long hours which the Company wanted him to work.

Mr. CLAUDE BAGGALLAY: With regard to these alternating-current motors, do you know as a fact whether there are many such motors in existence?

The WITNESS: I have not heard of very many. I do not know of one large one at the present time anywhere.

On Tuesday Mr. W. Emden, Chairman of the Strand District Board of Works; Mr. C. Mason, surveyor to the St. Martin's Vestry; Mr. H. Leslie, Manager *Pall Mall Gazette;* and Mr. J. Place, engineer to the Linotype Company, also gave evidence in support of the Charing Cross Company.

Mr. W. H. PATCHELL, engineer to the Charing Cross Company, stated that there was a demand for a supply of electric current by the Company for lighting purposes, motive power, and also for batteries. Though it was possible to use the alternating current for motors and battery work, it was not at present commercially practicable. There were difficulties in starting motors and in keeping them going when started. There were a few cases where the alternating current had been actually used for motors, but it was on an entirely different system to that used by the Metropolitan Company. The direct current was almost entirely used, he believed, for arc lighting, and it was undoubtedly the best for arc lighting, because it was steadier and gave a better light for the same amount of energy. Applications for motor purposes in the Strand district to the extent of 150 H.P. to 200 H.P. had been made to the Company.

In reply to Mr. Cripps, the WITNESS said that if the Metropolitan Company were to supply motors with direct current they would have to lay down fresh plant.

Mr. CRIPPS said that the Metropolitan Company could supply motors on the alternating system, but they were willing to supply them by the continuous system.

This closed the case for the Charing Cross Company.

Mr. F. BAILEY, managing engineer to the Metropolitan Company, was examined in opposition to the Order. He said that every application to their Company for a supply of current had been met, and with regard to the supply of motive power by continuous current, he stated that the Company would prefer to give a supply from an independent circuit, either continuous or alternating. They would be able to supply the direct current for motive power to anyone in the Strand district within a month or six weeks. The great difficulty in connection with motive power hitherto had been when one set of mains only was provided, the turning on of the motor introduced great fluctuations in the supply of the district. Therefore he preferred to have independent power circuits supplied from distinct sources. He did not at all understand what Mr. Vesey meant by there being no efficiency without a full load.

Lord KELVIN, who was one of the original advisers of the Metropolitan Company, said that they adopted the alternating system for supplying the Strand district after having consulted with him. The alternating current gave for ordinary purposes all the advantages of the rival system. He could not have told by the quality of the light whether it was coming from the alternating or the direct system. Either system might show dips or sudden diminutions or augmentations of the light through something going wrong in the engine room or battery room. When additional lights were thrown on the accumulator in the direct-current system there was a sudden change; with the alternating current, when the supply was shifted from one generator to another, there might be an instantaneous blink, but there was no more liability to such changes in the one system than in the other. Large and small motors could be supplied by the alternating system to practical advantage. He believed there was a certain percentage of saving in the cost of the direct system for large motors, but it would only be a question of 90 per cent. as compared with 92 or 93 per cent. He had seen electric motors working on the alternating system with perfect success and doing practical work. At Edinburgh and Brighton the two systems were at work very satisfactorily, and it was remarkable that at certain times of the day and year the two systems were interchanged; when it was not advantageous to work the direct current the alternating current was thrown on, and *vice versâ*.

In cross-examination by Mr. Claude Baggallay, Lord KELVIN said that the direct-current system was preferable for street lighting by arc lamps, and also for lighting in theatres, because of the slight hum there was in the electric arc lit by the alternating current. As to the merits of the two systems for motive power, he would scarcely like to say definitely, but the practical engineers who had had the question before them had provided an enormous amount of transmission of power by the alternating system He should personally prefer in every one of those instances to use the direct current, but there were some of the greatest engineers of Europe and America who were choosing the alternate system for the transmission of power and for the supply of motors, and if he had been in consultation with

Digitized by Google

those engineers he might have been led by them to prefer the alternating to the direct. Brown of Baden, the Oerlikon Works at Zurich, and Ganz of Budapest, all used the alternating current system, and did very great things indeed in the way of the transmission of power and supply of motors.

Mr. R. E. CROMPTON gave evidence as to the cost of laying down mains. Mr. H. Cooper, Mr. C. Hobbs, and Mr. H. J. Cole, members of the Strand Board of Works, opposed the introduction of a second company into the district.

Mr. S. Z. DE FERRANTI was examined as to the inconvenience which had resulted in the St. Martin's and other districts when the London Company, of which he used to be the engineer, was in competition with other companies. He stated that it meant the breaking up of the streets twice, and sometimes three times, for the purpose of making house connections, and the ultimate result was that the Companies had practically come to a working arrangement by agreeing upon their prices, so that now it did not really amount to competition.

Without calling on the promoters to reply, the Committee, after having consulted in private, agreed to confirm the Order.

THE DUBLIN UNITED TRAMWAYS COMPANY'S BILL.

The Dublin United Tramways Bill came before a Committee of the House of Commons, presided over by Mr. Roby, on Tuesday, June 24th. Mr. Littler, Q C , Mr. J. D. Fitzgerald, Mr. Munroe, and Mr. Richardson appeared as counsel for the promoters ; and the petitioners against the Bill were represented as follows :—The Clontarf Township Commissioners by Mr. R. Whitelaw ; the Rathmines and Rathgar Improvement Commissioners and the Pembroke Township Commissioners by Mr. Pembroke Stephens, Q.C., Mr. J. W. Greig, and Mr. P. N. Fawcett ; and the Corporation of Dublin by Mr. Pember, Q.C., Mr. Gerald Fitzgerald, and Mr. John O'Connor.

Mr. LITTLER, in opening the case for the promoters, said that they proposed to use electrical power in connection with the tramways, subject to the usual clauses imposed by the Board of Trade. They also proposed to employ either insulated returns or uninsulated returns, so that there would be no danger to persons using electricity for other purposes. There were three methods of working electrical cars. One was to have accumulators ; the second was to carry the electrical current in a grooved receptacle, or along one of the rails ; and the third, which was the one the Company proposed to adopt, was to carry the wires overhead by means of posts, supporting the wires on arms which were carried over the line. He handed in views of the tramways at Walsall and Vienna, which were worked on that system, and said that the posts would be ornamental, and would cause no interference ; they were made in such a way as to be perfectly useful either for electric lighting or as ordinary gas lamp-posts, thereby getting rid of the other posts in the street. He explained that the streets of Dublin were especially inapplicable to the carrying of the current in grooves beneath the roads on account of the amount of the wet and dirt and dust, while to carry it along the rails they would have to take up the whole of the tramway system, which would lead to great expense and inconvenience. In fact, they did not honestly see their way to incur the expense of introducing electricity under those circumstances.

Mr. GERALD FITZGERALD, on behalf of the Corporation of Dublin, said that they were not hostile to the introduction of electric power, provided that they, as the road and municipal authority, had sufficient control over it. They objected to overhead wires.

Mr. LITTLER said that that was objecting to the whole Bill, because the overhead wire system was the only one that could be used with advantage. In the United States the overhead wires were everywhere succeeding the clumsy and inconvenient method of the slot system running under the streets, and if the Committee should be of opinion that overhead wires were not admissible they might just as well reject the Bill.

Mr. JOSEPH KINCAID, engineer to the Bristol Tramways Company, said that that Company was carrying out an electric system by means of overhead wires, the principal portion of the road being through narrow streets. He was also consulting engineer to the South Staffordshire Tramways running from Walsall to Darlaston, which were also worked by overhead wires. From his experience in those cases he could say that all reasonable requirements of the Local Authorities had been met. He explained to the Committee the different methods of working with overhead wires, and said that the one which the Dublin Company proposed to use was similar to that in use at Walsall, where they had one conducting wire fixed on brackets at the side of the road. That system was in use at Brussels and Havre, but at Frankfort the span system was used. The streets in Dublin would present great objections to the adoption of the conduit system, as it would be necessary to make a conduit which could be kept dry. There was some considerable difficulty in that, as there was constantly a great deal of wet and dust and dirt entering the conduit, which it was difficult to remove. The maximum pressure which the Company proposed to use was 500 volts, which was the amount authorised by the Board of Trade. The accumulator system was objectionable on account of the weight which the accumulators added to the cars and from the fact that when they got near the end of the journey the power gradually weakened, and it had been known to give out altogether.

Mr. H. F. PARSHALL said that he had given special attention to electrical traction, and was familiar with the various systems in use on the Continent and in England. Over 99 per cent. of the cars were operated on the overhead system, but the conduit system was at use at Blackpool and at Budapest. As to the best system for Dublin, he should say that there should only be one system, and that would be by overhead wires. His Company in America had undertaken to construct about 6,000 miles of overhead wires, many of which were now working successfully. They were working with the cross wires, or what might be called the birdcage system. He thought, however, that the single-wire system would be more suitable for people who were somewhat strict in their requirements as to the appearance of the streets. Although the conduit system might be successful in Budapest it was not successful in Cleveland, Ohio, on account of the rubbish and rain that got into the conduit, the result being that it was impossible to keep it insulated. A poor slot system would be three times as expensive to erect as the single-wire system, while the very best slot system would cost seven times as much.

Mr. C. E. SPAGNOLETTI, consulting electrical engineer to the Great Western Railway Company, said that he thought that the overhead system was the best that could be adopted for certainty of work and economy, and was as safe for the public as could possibly be. He thought that the underground system would be especially objectionable in Dublin, on account of the humid climate and the heavy rainfall. It would be difficult to provide for the disposal of the storm water, and if the conduits got full of water it would be fatal to the system. He thought the overhead system would cause less obstruction to traffic. As to the question of speed he did not think that 12 miles an hour, at present allowed by the Board of Trade, would be dangerous in the streets, and at that speed the car would be perfectly under control. The birdcage system he considered very unsightly. He knew of no instance where an accident had been caused by the electrical part of apparatus in connection with the overhead system. Wherever there had been an accident it had been purely from mechanical conditions which were in no way connected with the electrical apparatus.

The Committee then adjourned till Wednesday, when Mr. Dickinson, engineer to the Walsall Electrical Tramways, gave evidence to the effect that the Local Authorities of the town, now that the overhead system had been in working order for some time, and no doubt realising its advantages, were anxious for its extension. That system passed through the main streets of a very populous district, and he had never heard complaints arising from inconvenience to traffic. He concurred in the objections to the underground system. His experience of the Board of Trade was that they were more cautious in the matter of the use of electricity than the Local Authorities, and in view of the way in which they protected the public he thought the opposition which the Dublin Corporation were raising to this scheme could hardly be described as reasonable.

Mr. WILLIAM ANDERSON, secretary and manager of the Dublin Company, said that the system extended about 32 miles. A Committee of the Company had inspected the various electrical systems in England and on the Continent, the result of which was that the Committee came to the conclusion that electric tramways were worked more easily and expeditiously than any other kind, and cause no inconvenience to the public.

Mr. W. MURPHY, a Director of the Company, who formed one of the Committee of Inspection, also gave evidence.

This closed the case for the promoters, and Mr. Cripps addressed the Committee on behalf of the Dublin Corporation, urging that the Committee ought not to sanction the Bill in face of the opposition of the Local Authorities. In all such Bills it was strictly stipulated that the powers were not to be used except with the consent of the Local Authority, and if this Bill were carried it would be running in the teeth of every precedent.

The LORD MAYOR of DUBLIN was then examined in support of the objections of the Dublin Corporation, maintaining that the veto of the Local Authority ought to be sustained. For the purposes of the Bill openings would have to be made in the streets, and he looked upon that interference with the streets in the same way that he should look upon the laying of a new track. Until the Corporation came into that room they had not the faintest idea as to what system the promoters would adopt, and even now they were not certain what system really would be adopted if the Bill were passed. In cross examination by Mr. J. D. Fitzgerald, he said that the consent of the Corporation was a matter which was open to arrangement, and that an arrangement might be come to by payment. He did not see why any company who would make a profit by such a concession should not be made to pay for it. Wherever electricity was introduced it should be subject to the consent of the Local Authority.

Mr. J. D. FITZGERALD having replied on behalf of the promoters, the committee room was cleared, and, after a short private consultation,

The CHAIRMAN said the Committee had been very much impressed with a good deal of the engineering evidence, and if they were members of the Dublin Corporation they might be disposed to give a favourable hearing to the Company, but they were not prepared to allow this large change to take place without the consent of the Local Authorities, and consequently they had so far to find the preamble of the Bill not proved. Of course, Mr. Fitzgerald would tell them whether the Company were prepared to go on with the Bill with some words inserted to require the consent of the Local Authority.

Mr. FITZGERALD said he should like to consult his clients as to whether they would take the Bill at all or whether they would take it just so far as it applied to the townships which raised no objection.

The CHAIRMAN said that was quite reasonable, and the Committee adjourned till the following day.

On Thursday Mr. J. D. FITZGERALD said that what the promoters proposed to do was to strike the city of Dublin and the townships of Pembroke and Rathmines out of the Bill, and to amend the Bill so that it would only refer to those parts of the tramways with respect to which no objection was taken. The city of Dublin and those two townships being the objecting parties, and being entirely struck out of the Bill, the Bill would have no effect on them.

Mr. PEMBROKE STEPHENS asked if anything could be more senseless than to have a system of electrical working right up to the boundary of the city and then change it,

Digitized by Google

The CHAIRMAN said that he quite agreed with that view, but as the Committee would cut out of the Bill all that related to Dublin, Pembroke, and Rathmines, he thought that was all that Mr. Pembroke Stephens could fairly ask for.

The clauses of the Bill were then gone through and amended in accordance with the decision of the Committee, and the Bill was ordered to be reported to the House.

PARIS NOTES.

(FROM OUR OWN CORRESPONDENT.)

PARIS, *July 18, 1895.*

Electrical Awards.—At the meeting of the Société d'Encouragement on Friday last, presided over by M. Mascart, the following prizes were awarded in the Electrical Section. A prize of 500fr. was given to M. Lartigues, head of the outdoor service of the Municipal Central Station at the Halles Centrales, and a similar prize to M. Gaston Roux, head of the Bureau de Contrôle des Installations Electriques, for their memoirs on the measurement of the insulation resistance of a distributing network of a central station when at work. A silver medal was also given to M. J. Laffargue, municipal electrical inspector, for his work on "Electric Fitting Machinery."

Electrical Legislation.—The Senate has just passed a Bill relating to the erection of electric conductors, and the aggressive decree of May 15, 1888, has been abrogated. By this law no electrical conductor, other than a telegraph or telephone line, may be established above or below a public road without prefectoral authorisation, which is to be given under advice from the Postal Telegraph Department. Overhead conductors are not to be placed closer than 10 metres to a telegraph or telephone line without special permission from the Postal Telegraph Department. The Minister of Commerce, after taking the advice of his electrical advisers, is empowered to draw up rules with regard to the existing conductors which are likely to interfere with the telegraph or telephone service. The owners of existing lines likely to interfere in this manner are to be informed, within six months from the promulgation of the law, of the alterations that must be made; and within a year of notification these alterations must be carried out. Perhaps the most noticeable feature of the law is the fact that the Minister of Commerce is authorised to form a permanent Advisory Council, one half of which is to be composed of representatives of the electrical industry. This Council is to advise the Minister of Commerce with regard to rules and regulations on all electrical questions upon which he may desire their opinion.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *June 28, 1895.*

Mr. A. E. Kennelly.—Mr. A. E. Kennelly has received from the Western University of Pennsylvania the degree of D.Sc. in recognition of his scientific work in connection with cable testing and alternating current. His recent contributions on the subjects of inductance and capacity, and the application of complex quantities and simple graphical methods in the consideration of these, are specially mentioned.

The Berliner Patent Litigation.—The opinion of the United States Circuit Court of Appeals, reversing the recent decision of Judge Carpenter declaring void the Berliner variable pressure constant-contact telephonic principle, is extremely positive in its tone, and displays little patience with the allegations of fraud and collusion in the issue of the 1891 patent in suit. Its conclusions are that the delay of 14 years in the issue of the patent is to be ascribed solely to imperfections in our patent system, and that as the issue of the patent was within lawful authority of the Commissioner of Patents, the question of its anticipation by the 1880 Berliner patent is one over which the Courts have no jurisdiction in the present action. The net result of the litigation thus far is to probably dispose definitely of the fraud issue, but leaves open the question of anticipation, with the weight of one adjudication against the Bell Company—that of Judge Carpenter—though the reversal of his decision on the fraud issue leaves this without effect. We learn that the recently-formed national organisation of telephone manufacturers proposes to test the patent by having one of its members become a defendant on an infringement issue, which will bring the matter before the Courts without the legal complications that have surrounded the Government suit.

The Westinghouse Electromagnetic Railway.—For several years it has been known that Mr. George Westinghouse, jun., has been experimenting with a novel electric railway system. It seems, however, that Mr. Westinghouse was anticipated in the Patent Office by another inventor, Jerome Wheless, and a few days ago the announcement was made that Mr. Westinghouse had purchased the patents of the latter from the owners, the Electromagnetic Traction Company, which has for some time been operating an experimental line in Washington. At the same time the details of construction and operation were made public, from which it appears that the system is of the class that employs a storage battery current in the car to operate a magnet that in turn switches on the motor current. The magnet and switches are situated in an underground box which may be placed under the sidewalk or wherever convenient. In the centre of the track are three fixed projections, with which, when the car passes over them, brushes on the car make contact. One brush conveys the current of a three-cell storage battery to a magnet in the switch-box, which switches on the motor current. This current then passes through the second contact pin and brush to the motor, whence through the third brush and pin it passes to the return cable. The electrical public will await with much interest the verdict as to whether this system contains the elements of commercial success, or is to be classed merely as an inventor's hobby.

CORRESPONDENCE.

WAVE FORM SYNTHESIS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The idea of employing a special armature as suggested by Dr. Fleming, for the production of synthetic waves of potential difference or current, occurred to the writer some months ago. In considering the problem of constructing some simple form of harmonic synthesyser with Mr. Archibald Sharp, the writer suggested the idea of using an electrometer or galvanometer and tracing out with a light spot on a moving photographic plate any Fourier function which was to be made up by prearranged "harmonics"—the latter being electrical sine waves derived from a suitable source. It was proposed to employ an armature made up of separate parts—each being a complete Ferranti armature in itself—and the parts were to have respectively, say, 6, 12, 18, 24, 30, 36, &c., flat coils or bobbins, while the field was to have, say, 6 poles.

A rough idea of the arrangement is given in Fig. 1, a sketch made by the writer some time in February. Here three elemental armatures are represented in section. Armature 1 would have, say, 6 coils, 2 would have 18 coils, and 3 would have 30 coils. This is the arrangement proposed by Dr. Fleming, and was intended to give, when the elemental armatures were connected in series, as shown, a potential difference wave between T_1 and T_2 which would be the sine function of the fundamental, third, and fifth harmonics.

The rheostats R_1, R_2, R_3 enable one to adjust the relative amplitudes.

The writer suggested that for the automatic synthesyser (which was to be used for mathematical as well as electrical work) a small special alternator could be fitted with a set—say up to ten—of small thin coil elemental armatures, as described, so that any number or order of these could be fitted to the common shaft at will.

With the circuits of the elemental armatures connected in series we would have a wave form which, if drawn automatically

Digitized by Google

upon a moving photographic plate, or, for current waves, by the tracing of a pen or pencil upon a moving screen, would give us a very simple means of plotting Fourier functions.

Messrs. Burnie and Rodgers, of the Central Technical College, and the writer, have been working out the details of a curve tracer for the above purpose for some months past, but we are not at liberty to give the particulars of this instrument in the present letter.

One difficulty with the employment of elemental armatures in a single field, which may not have occurred to Dr. Fleming, is as follows: For the fundamental wave armature and the lower harmonic elements the distance between the field poles

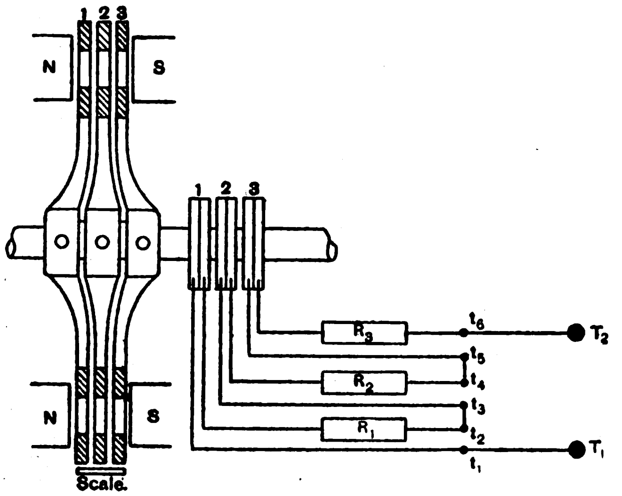

Fig. 1.

would be exaggerated, and hence the waves of low frequency could have a form something like that shown in Fig. 2, which is not a sine function. Practically speaking, with poles far apart there is a considerable angular distance midway between them, where the rate of change of lines is very low and nearly constant. Hence the wave of induced E.M F. is not a sine function.

For the mere production of *irregular* synthetic waves this would not matter, except that there would be no way of knowing the equation to the resultant graph.

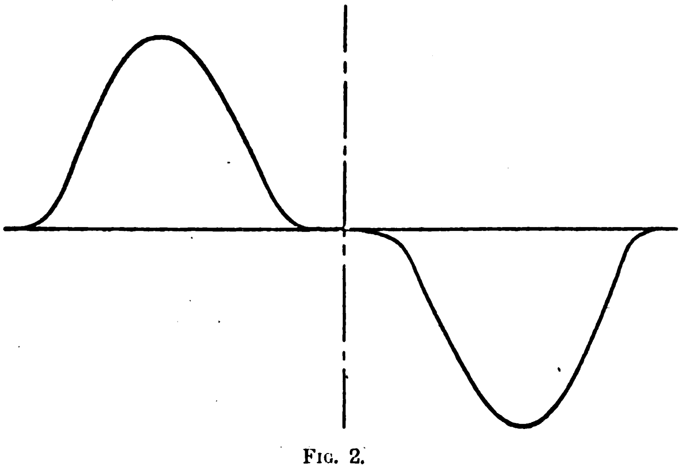

Fig. 2.

For the purpose mentioned by the writer it was therefore considered better to have separate field sets. It was also suggested to have sets of *similar* elemental armatures revolving in a common field, geared (with loose bearings on one shaft) to run at respective speeds which would give the successive frequencies required for the resultant graph sought.

A second method for producing synthetic electromotive force waves has been found feasible for use with the automatic synthesyser roughly described above, and the writer hopes to give the details later.—Yours, &c., JAMES MARK BARR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Kindly allow me to correct an error in Messrs. Barr, Beeton, and Taylor's Paper on the above subject, which appeared in your last issue.

At the bottom of column 2, page 287, they attribute to me a special method of connecting up an electrometer, which gives both proportionality and equal sensibility on the two sides of zero.

The method has been very frequently used during late years at the Central Technical College, but I can lay no claim to it, having come across the arrangement in Mascart and Joubert's well-known treatise.

I would also point out that the claim for greater sensibility mentioned in lines 8 to 11, column 1, page 288, presupposes that N and $\frac{a+b}{2}$ are of the same sign.—Yours, &c.,

T. MATHER.

SHIPBOARD GALVANOMETERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On reading Mr. Wilkinson's able article on "Shipboard Galvanometers," published in your last issue of *The Electrician*, I notice that he states, "the spot oscillates some time before coming to rest." This is, of course, due to the very small damping of the old system.

Mr. Wilkinson seems to be unacquainted with the new method devised by Mr. Weatherall and myself, which produces an almost dead-beat movement, the spot coming to rest well within two seconds. (This is made by Messrs. Elliott Brothers, where it can be seen.) The sensitiveness of the instrument is not to the slightest extent impaired—in fact, a much greater degree of efficiency is obtained.

Mr. Wilkinson also mentions the difficulty of reading electrostatic discharges on the marine galvanometer; this we have completely overcome, and they now can be observed as readily as with the ordinary astatic galvanometer. Further, by our method of damping, an ordinary testing instrument can be used for mirror speaking, and perfect signals can be obtained through lengths varying from 1 to 2,000 or more knots of cable. This method is an adaptation to the marine galvanometer of a system we have had in use with our astatic galvanometers for the last three years.—Yours, &c.,

THOMAS CLARK,
Electrician to the Telegraph Construction and Maintenance Company.

East Greenwich, July 2, 1895.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The instrument mentioned by Mr. Clark as designed by Mr. Weatherall and himself is of considerable interest and importance. I am quite sure that many besides myself would be glad to be referred to any published description of it. A few weeks ago a description of a damping arrangement designed by Mr. H. W. Sullivan appeared in this journal, which seemed capable of adjustment without bringing in too great a logarithmic decrement in discharge work. Results obtained, showing return to zero and absence of creeping, would be of great practical value.—Yours, &c., H. D. WILKINSON.

Wimbledon, July 4, 1895.

MAGNETIC SYMBOLS AND TERMS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The interesting correspondence in your current number about magnetic symbols and the use of the term "gauss" shows that there is still some difference of opinion on this point.

I venture to suggest that instead of a unit of magnetic intensity **B**, what we really want is a unit of magnetic flux analogous to the ampere. The term "magnetic line of force," used by some as the unit of magnetic flux, does not convey an accurate idea of the nature of the quantity which is measured. The Kapp line is open to a similar objection.

For some time I have been in the habit of using in calculations the term "mag" to denote the C.G.S unit of magnetic flux, and have found it extremely convenient. **B** can be

Digitized by Google

readily expressed in "mags" per square centimetre or "mags" per square inch according to the system of measurement in use, just as current density can be expressed in amperes per square inch or in amperes per square centimetre. The terms "erg" and "dyne," which are universally employed as the names of units, would form a precedent for the adoption of the term "mag" as the unit of magnetic flux.—Yours, &c,

J. A. Kingdon.

29, Marlborough-hill, London, N.W.,
July 1, 1895.

LEGAL INTELLIGENCE.

Edison and Swan United Electric Light Company v. Williamson.

In the Chancery Division of the High Court of Justice on Thursday the case of the Edison Swan Company v. Williamson was mentioned to Mr. Justice Stirling, it being an action to restrain the alleged breach of a licence.

Counsel for the plaintiff Company said that the defendant had given an undertaking in the terms of the notice of motion, and the action would be at once set down for trial, and the motion for an interim injunction would stand over on those terms until the trial of the action.

Counsel for the defendant said that the undertaking was given without prejudice, because his client contested the plaintiffs' case altogether. It was, however, a case in which there must be cross-examination, and that would best be taken at the trial.

His Lordship directed the motion to stand over on those terms.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

SPECIAL NOTICE.—The 1895 (thirteenth) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. In addition to the old well-known features of the book, which are brought up to date, a quantity of new and useful matter has been added, rendering the book more than ever indispensable to the Electrical, Engineering, and Allied Trades. Price, 7s. 6d., post free 8s. 3d., abroad 9s.

The following New Books and Editions of "The Electrician" Series *can be obtained of the Booksellers or direct from the Publishing Offices:—*

Laboratory Notes and Forms.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett (*now ready*). Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"Electric Lamps and Electric Lighting," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

A Large-Sheet Table, giving full particulars of the Electricity Supply Stations throughout the Kingdom, can now be supplied mounted on stout board, with cord for hanging. Price: Varnished, 3s. 6d.; Unvarnished, 3s. —each post free. A Map showing positions of Supply Stations throughout the country is mounted on the back of the Table, and a Coloured Map of Metropolitan Electric Lighting Areas and a large sheet of Electricity Supply Statistics are also mounted on some copies, the price of which complete, post free, is 5s.

A Sheet Table showing Total Capital Outlay and Receipts and Expenditure for the year 1894 of the Statutory Electric Supply Undertakings of the Metropolis is now ready, printed on thick paper, price 6d. each.

"The Work of Hertz."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"Electrical Engineering Formulæ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"Drum Armatures and Commutators."—By Mr. F. Marten Weymouth, is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"The Incandescent Lamp and its Manufacture."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

Tenders Invited.—The Brighton Borough Council invite tenders for the supply and erection of steam and feed piping, cast-iron storage tanks, feed water filters, electrically-driven feed pumps, circulation economiser, coal elevator and sundries. Also and erection of evaporative brass-tube surface condensers, electrically-driven air pumps, exhaust and condenser piping. Specifications may be obtained at the offices of the Town Clerk (Mr. F. J. Tillstone), Town Hall, Brighton, and tenders, addressed to Mr. Tillstone, must be sent in by 10 a.m. on Monday, the 15th instant. Some further particulars appear in our advertisement columns.

——— From our advertisement columns it will be seen that the Metropolitan Asylums Board require tenders for the supply and running of mains in the grounds, and for the wiring of buildings now being erected at the North-Western Fever Hospital, Haverstock Hill, N.W. Copies of the conditions and specifications may be obtained at the offices of the Board, Norfolk House, Norfolk-street, London, W.C., and tenders must be sent in by 11 o'clock on Thursday, the 18th inst.

——— The chief of the I. Regiment "Cetate," in Focsani, Roumania, are inviting tenders for the supply of 5,000 metres of telephone cable and eight sets of station apparatus.

——— The municipal authorities of Cullera, Valencia, Spain, invite tenders until the 8th inst. for the concession for the electric lighting of the streets for a period of 20 years. Tenders to the Ayuntamiente de Cullera.

——— In connection with the recent decision of the municipal authorities of Dortmund to establish an electric supply station in the town, a competition for the carrying out of the scheme is announced. Competitions are to reach the Magistratsamte, Dortmund, by August 14th next. Conditions, &c., may be obtained on payment of 1s.

——— The Town Council of the Borough of Richmond, Surrey, require tenders for an extension of the fire call system within the borough. Tenders must be sent in to Mr. Frederick B. Senior, town clerk, Town Hall, Richmond, Surrey, by 2 o'clock on Monday next, July 8th.

——— The Directors of the Manchester Ship Canal Company invite tenders for the necessary work for the permanent electric lighting of the Manchester and Salford Docks. Tenders, addressed to the secretary (Mr. A. H. Whitworth) must be in by July 10th.

——— The Visitors' Committee of the Bristol Lunatic Asylum, Fishponds, Bristol, require tenders for supplying and fixing wires, lamps, &c., for lighting the Asylum by electricity. Tenders to be in by July 15th.

——— The Corporation of Portsmouth invite tenders for the supply and erection of conduits and india-rubber covered electric mains, and for the supply and erection of "compound" covered high-tension electric mains. Tenders must be sent in to Mr. A. Hellard, town clerk, Town Hall, Portsmouth, by 6 p.m., July 10th.

——— The Urban District Council of Wellington (Salop) invite tenders for lighting the district by electricity or gas. Tenders before noon on Monday, July 15th.

——— The Parish Council of Hapton (Lancs.) require tenders for the electric lighting of the village from September 1st next to April 30, 1896. Tenders must be sent in to the Chairman of the Council before the 15th instant.

Tenders Accepted.—In our last issue particulars were given of the acceptance of the tender of Messrs. Clay Brothers and Co. for the electric lighting of Messrs. Hancock's brewery at Cardiff. The following is the complete list of tenders:—

	£	s.	d.
Clarke, Chapman and Co. (Gateshead-on-Tyne)	£1,705	0	0
Barclay and Son (London)	1,640	0	0
Easton, Anderson and Goolden (London)	1,579	15	0
Wilson (G.) and Co. (Aberdare)	1,578	19	0
Laing, Wharton and Down (London)	1,572	10	0
Lewis and Fletcher (Cardiff)	1,477	0	0
Knapman, Hodder and Co. (Cardiff)	1,420	6	0
Saunders and Co. (Cardiff)	1,420	0	0
Strode and Co. (London)	1,387	0	0
Clay Brothers and Co. (Cardiff (accepted)	1,337	17	0
Fergus and Co. (Cardiff)	1,245	0	0

——— The following tenders have been received for the electric lighting of the Presbyterian Church of England, Newcastle-on-Tyne:—

	£	s.	d.
S. Bury	£63	0	0
R. J. Charleton and Co. (accepted)	80	0	0
Wynne and Barnard	82	10	0
Reid (F.), Ferens and Co.	95	0	0
Rowland Barnett and Co.	110	16	7
Ernest Scott and Mountain	118	0	0
Bland Brothers	168	10	0

[All of Newcastle-on-Tyne.]

——— The Electric Light Committee of the Belfast Corporation have accepted the tender of Messrs. S. Z. de Ferranti (Limited) for the supply of meters.

Digitized by Google

Tenders Accepted.—The contract for the equipment of the Manhattan elevated railway in New York for electric traction, at an estimated cost of over a million pounds sterling, has, it is stated, been secured by the Westinghouse Company.

——— *Correction.*—It our issue of June 14th it was stated that the tender of Messrs. Knapman, Hodder and Co., of Cardiff, being the lowest, had been accepted for the lighting of the Cardiff Free Library. We are asked by Messrs. Strode and Co. to state that this is an error, Messrs. Strode's tender having been accepted.

——— On the recommendation of the Watch Committee the Birkenhead Town Council have accepted the tender of Messrs. W. A. Shaw and Co., of Stockport, for the erection and establishment of a fire-alarm system for the town for the sum of £835.

Tenders Received.—The Electric Lighting Committee of the Wolverhampton Town Council have decided to recommend the acceptance of the following tenders for plant for the electric lighting extensions :—

Thomas Parker (Limited) (dynamos, &c.)	£2,232
Marshall, Sons and Co. (steam engine)	845
Callender Company (extension of mains, &c.)	536

Business for Sale.—As will be seen from our advertisement columns, Mr. J. M. Macleod (liquidator under the sequestration of the estate of Mr. J. Scott, trading as D. and G. Graham) has for sale the business of electrical engineers, bell-hangers, &c., hitherto carried on by Mr. Scott, at 134 to 140, Douglas-street, and of wholesale and furnishing ironmongers at 201, Byars-road, Glasgow, together with the stock in trade, plant, machinery, and book debts. The business has been established over 50 years. The stock, plant and machinery may be seen on application to Mr. J. Macleod, 101, St. Vincent-street, Glasgow, who will give facilities for inspecting the works.

Appointment Vacant.—The Bradford Corporation are prepared to receive applications for the appointment of engineer to take charge of their electricity works at a commencing salary of £300 per annum. Applications must be sent in to Mr. W. T. McGowen, Town Clerk, Town Hall, Bradford, by the 17th inst. Some further particulars are given in our advertisement columns.

——— The Governors of the Northern Polytechnic invite applications for the post of principal. After the 25th March next the stipend will be at the rate of £500 per annum, and from September 29th next to March 25th at the rate of £300 per annum. Applications must be sent in to Mr. E. Griffiths, secretary, St. Mary's Vestry Hall, Islington, N., before July 15th.

——— The Birmingham Corporation requires an engineer, competent to take entire charge of the electric light and power installation in the new Municipal Technical School. Salary £2. 10s. per week. Applications, stating full particulars, must reach the Secretary (Mr. Geo. Mellor), Paradise-street, Birmingham, by the 13th inst. Some additional information is given in our advertisement columns.

——— The Governing Body under the Swansea Intermediate and Technical Education Scheme require a head master. A minimum salary of £600 per annum is guaranteed. Applications are to be sent in by Monday, the 15th inst., to the Chairman of the Governing Body, Guildhall, Swansea.

Appointment.—Mr. A. G. Ashcroft, formerly assistant to Prof. Kennedy, at present assistant in the laboratory of Prof. Baird, of University College, London, and lecturer on engineering at the People's Palace, London, E., has been appointed Principal of the Woolwich Polytechnic in place of Mr. Garrett, resigned. The commencing salary is £350 per annum.

——— Mr. Sydney W. Baynes, at present electrical engineer to the Bradford Corporation, has been appointed chief electrical engineer to the St. Pancras Vestry. The salary attached to the office is £600 per annum.

New Address.—The Nalder and Harrison Construction Syndicate (Limited) have now removed to their new address at Bow Common-lane, London, E. Telegrams: *Lucimeters London.* Telephone No. *5064.*

Liquidations.—At a meeting of the shareholders in Galloways (Limited), boiler makers, Manchester, a resolution was passed on June 10th last to the effect that it was desirable, for the purposes of reconstruction, that the Company be voluntarily wound up. This resolution was confirmed on June 25th, and Mr. J. W. Pollitt, of Marsden-street, Manchester, was appointed liquidator, with power to consent to the registration of a new company with the same title.

——— A resolution was passed on May 8th last, and confirmed on June 6th, that it was desirable to reconstruct the Otis Steel Company (Limited), and that the Company be wound up. Mr. A. Young, of Coleman-street, London, E.C., was appointed liquidator. On the 29th ult a petition for the winding-up of the Company was adjourned till Wednesday next.

——— In connection with the winding-up of the Agence Dalziel (Limited) the Official Receiver has issued the usual summary, and in his observations thereupon calls attention to the peculiar methods adopted in order to find capital for the flotation of the concern, the failure of which is by Mr. Dalziel attributed to the expenditure having exceeded the income owing to excessive competition, to the attacks of the Paris Press, and other similar causes.

Personal.—Mr. Reginald J. Wallis Jones, A.M.I.C.E., M.I.E.E., has been appointed engineer and manager of the Electric Welding Company (Limited).

Agency.—Messrs. George Piggott and Co., of Cannon-street, E.C., inform us that they have been appointed sole London agents for Messrs. C. E. Collins and Co., electric light fittings manufacturers, of Birmingham. Messrs. Piggott are also agents for Mr. F. M. Newton.

Aberystwyth.—Mr. A. H. Preece has presented a lengthy report on the electric lighting of the streets by the local electric light company. Mr. Preece expresses satisfaction with the result of his inspection, and recommends that the Council procure a photometer for the purpose of recording the power of the light.

Blackpool.—At their last meeting the Town Council considered the Electric Lighting Committee's report, which recommended that a Sub-Committee be appointed to consider Mr. Hammond's report on the present position of the electricity works, and that until a further extension of the electricity works be made no further applications for electric current be entertained. Councillor Pearson, in moving the adoption of the report, said that the present plant at their station was taxed to its fullest capacity, and the Committee would ask at an early date for power to largely extend the works. So far the electric light had proved an unqualified success, and the balance-sheet for the past year showed that they had made a gross profit of £1,604. Their total expenditure during the year was £3,877, while the receipts were £5,481; £1,409 was set aside for depreciation and interest, and £600 for sinking fund, thus showing a net loss of £278.

Bolton.—The Gas and Electricity Committee of the Town Council have instructed their electrical engineer (Mr. J. H. Rider) to prepare a scheme for furnishing a continuous supply of electricity throughout the borough. At present the current is switched off at midnight. A sub-committee has been appointed to consult with the Streets Committee on the question of electric traction on the Corporation's tramways.

Church Lighting.—St. Margaret's Church, Prince's-road, Liverpool, is now lighted throughout by electricity.——The United Methodist Free Church at Burnley has been fitted throughout for the electric light.

City of London.—At the meeting of the Court of Common Council last week a report was presented from the City Lands Committee asking authority to appoint Mr. A. A. Voysey as consulting electrical engineer to the Corporation at an honorarium of £50 per annum, subject to annual election by the Committee. The proposal met with considerable opposition, and ultimately the report was negatived. In the course of the discussion it was stated that the cost of electric current supplied to the London Corporation in 1893 was £387, and in 1894 £513; gas in 1893 £1,312, and in 1894 £882.

Cork.—The Cork Electric Light and Power Company (Limited) have notified the Corporation of their intention to apply for a Provisional Order enabling them to supply the city with electric current for public and private lighting.

Country House Lighting.—Mr. A. H. Browne, M.P., has instructed Messrs. Drake and Gorham to instal the electric light throughout Broome Hall, Holmwood.

Decimal System.—The Select Committee of the House of Commons on Weights and Measures has recommended that the metrical system should be legalised experimentally for two years, and should thereafter become compulsory.——An instructive Paper was read by Mr. J. L. Wilkinson on "The Decimal System" before the members of the International Railway Congress now sitting at the Imperial Institute. Mr. Wilkinson pointed out that the whole of the civilised countries of the world, except Great Britain and some of its important colonies and dependencies, had introduced the decimal system in some shape or form.

Eastbourne.—In deference to a request from the Town Council, the local electric light company have decided to make a reduction of 1d. per unit in the price of current supplied to the Town Hall and band stand from the 30th ult.

Eccles.—The minutes of the Watch Committee, presented to the Town Council on Monday, stated that Mr. S. V. Clirehugh, the Council's consulting electrical engineer, had prepared a report on the proposed electric lighting scheme, in which provision had been made for lighting the whole of the area covered by the Council's electric lighting Order, together with such private lighting as the Committee considered it was reasonable to anticipate. It was estimated that a capital outlay would be involved of £18,971, but

Digitized by Google

that no charge upon the rates would be necessitated, as the income, after allowing for expenditure, was estimated to leave a small surplus in favour of the scheme. If the public lighting of the district only were undertaken, it was calculated there would still be a balance in favour of the electric light of about £130, as the capital outlay figures would be reduced to about £15,000, and the annual upkeep, &c., to £1,560, against £1,690 now paid for gas. The Committee, after carefully considering this report, had decided to adopt it, and to recommend that application be made to the Local Government Board for powers to borrow £19,000 to carry out the scheme. It was pointed out by Mr. Alderman Kendall that the Board of Trade, having been informed of the proposed action of the Corporation, had deferred considering the question of the revocation of the Order until June 9, 1896, when, if some scheme was not in process of being carried out, the Order could be revoked, and it was more than likely that a private company would step in. After some discussion the Committee's minutes were approved, and application is to be made to the Local Government Board as above-mentioned. Plans and specifications are being prepared, and are to be considered at an early meeting of the Council.

Edinburgh.—At a meeting of the Electric Light Sub-Committee of the Town Council on Tuesday last, it was unanimously resolved to recommend that, in view of the various extra duties undertaken by Mr. Monkhouse (borough electrical engineer), and which were not included in the terms of his appointment, and having regard to the large salaries paid to similar officers in other cities, his salary be increased from £300 to £400 per annum. The Sub-Committee gave further consideration to the scheme authorised by the Town Council for the extension of the high-tension mains to the south side of the city, and every effort is to be made to expedite the works so as to ensure the supply of current by the beginning of the winter.

Electric Calls.—Several of the principal clubs and hotels in London are provided with a useful electrical device for cab-calling. In lieu of the discordant whistle formerly used, two lamps are suspended outside the building, one coloured red and the other green, and by pressing a knob in the entrance hall the hotel attendant shows one colour or the other. If a red light is shown cabmen are made aware that a four-wheeler is required, and if a green light that a hansom is wanted.

Electric Welding.—The Electric Welding Company (Limited), of Hindon-street, Pimlico, S.W. (owners in this country of the Thomson patents), exhibited at the *conversazione* held at the University College, Gower-street, W.C., on the 27th ult., an automatic wire-welding plant. It is stated that the use of wire-welding plants in America is almost universal, and the Company is making considerable progress in the introduction of these machines amongst wire and cable manufacturers in Great Britain.

Expansion of Telegrams.—It will be remembered that some weeks back *The Times* took strong exception to the course adopted by the Central News Agency in dealing with telegrams received in connection with the war between Japan and China. The *Daily Chronicle* understands that the conductors of *The Times* have decided to take legal proceedings against the Central News Company "for alleged breach of contract in connection with the 'expansion' of telegrams from the far East during the late war." If this course is adopted the case is likely to prove of great public interest.

Hull.—At a meeting of the Electric Light Committee of the Corporation, held last week, a report was read from the deputation, consisting of representatives from Hull, Blackpool, Bradford, Brighton, Lancaster, Wolverhampton, Glasgow, &c., which waited upon Major Cardew a few days back to place before him the views of the various Corporations on the revised Board of Trade regulations. The report states that Major Cardew gave general sympathetic consideration to the views expressed by the deputation, and promised, if it was found necessary, that the Board of Trade would later on convene a meeting of the Corporations and others interested in the supply of electric current for the purpose of obtaining a full discussion of the proposed regulations before they became law. It was pointed out that the regulations respecting voltage, if insisted upon, would seriously affect the Hull station.

International Railway Congress.—At a meeting of the delegates at this Congress on Tuesday a Paper was submitted by MM. Scolari and Rocca, officials of the Mediterranean Railways of Italy, on the subject of the 24-hours day, strongly recommending the railway authorities to adopt this system, which, the writers urged, would bring about genuine advantages, especially in the telegraph and railway services. By its adoption in the telegraph service mistakes that now easily occurred would be avoided, and there would be a saving in transmitting unnecessary signs. The writers estimated that in the system of the Western Union Telegraph Company a saving of the transmission of 150,000,000 letters annually would be effected out of the 44,000,000 messages a-year transmitted by that Company.

Limavady (Ireland).—At the last meeting of the Board of Guardians notice was received from Mr. J. E. Ritter, J.P., of his intention to apply for a Provisional Order to light by electricity a district of the Limavady Union. Mr. Hopkins thought that the shareholders in the Limavady Gas Company would not like to hear of this. Mr. Given said the shareholders in the Company did not care. Sir Thomas Leckey said that Mr. Ritter was to be congratulated on introducing the electric light into the Union. The notice was ordered to be put on the minutes.

Liverpool.—At the last meeting of the Special Lighting Committee it was stated that there was a good prospect of the Bill for the acquisition of the local electric supply company's undertaking being passed through Parliament this year. The Committee intend to apply for a Provisional Order to enable them to supply electric current to the whole of the city.

Nottingham.—Messrs. Calvert and Co., of Exchange-buildings, Manchester, have obtained a contract for lighting electrically Colwick Hall and Grounds, Nottingham. The installation, which is for 24 2,000 c.p. arcs, is to be completed by the 1st prox. Messrs. Calvert and Co., although a comparatively new firm in this country, notify that they are very busy in the contract department.

Omnibus Lighting.—Many attempts have been made, with more or less success, to light the omnibuses of the London General Omnibus Company and the London Road Car Company, but recently these attempts have been abandoned. A trial has, however, for the past two or three weeks been made on some of the 'buses of the London General running between Broad-street station and Westminster, and the lighting has so far proved satisfactory, the conductors affirming that no trouble has been experienced during the experiment, which is at present only on a small scale.

The Pacific Cable.—This week's bulletin is to the effect that the Vice-President of the San Francisco Chamber of Commerce, from thorough inquiries made, is convinced that a Pacific cable will shortly be laid by a group of British capitalists. The route chosen is from Auckland to Vancouver, by way of Norfolk Island, Fiji and Fanning Island. This very important information comes through Reuter's Agency.

Peterborough.—At the last meeting of the City Council the salary of Mr. J. C. Gill, the city engineer, was raised from £275 to £375 per annum, in consideration of his performing the additional duties of electrical engineer.

Provisional Orders.—The Carlisle Electric Lighting Provisional Order has been passed by both Houses of Parliament.

Redcar.—At the last meeting of the District Council a letter was read from Messrs. Stacey and Bennett stating that the cost of introducing the electric light for the public lighting of the district exceeded their unaided capabilities, and asking the Council's support in forming a company. It was agreed to appoint a committee to meet Messrs. Stacey and Bennett to consider the question.

Shanghai.—The Municipal Council have received plans for the construction of about 25 miles of tramway on the overhead electric system.

Snaefell.—The electric railway is rapidly approaching completion, and will, it is expected, be ready for opening in a few weeks. The railway opens out magnificent mountain scenery, and goes to the summit of Snaefell, the highest mountain in the Isle of Man.

Society of Engineers.—On Wednesday last the members of this Society visited the central station of the Dover Electricity Supply Company (Limited).

Stretford.—At the last meeting of the District Council a letter was read from the Manchester Suburban Electric Supply Company (Limited) intimating their intention of applying in the next Session of Parliament for a Provisional Order to enable them to supply the district with electric current, and asking for the sanction of the Council to the application. After some discussion the communication was referred to the Highways Committee for consideration and report.

Telephone Trunk Lines.—Interesting and successful experiments with the trunk telephone wires between the Exchange Post Office, Liverpool and the General Post Office, London, took place on Monday last before the Lord Mayor, the President of the Liverpool Chamber of Commerce, and representatives of the chief shipping firms. The object of the experiments was to test the utility of these wires, with which it is intended ultimately to connect the chief towns of the kingdom. Conversations were carried on between Mr. Spencer Walpole, the secretary of the Post Office, and several other leading officials, as well as with Glasgow and Leeds. Similar trials of the trunk lines took place at Bristol on the same day, the results proving highly satisfactory.

Digitized by Google

UP-RIVER STEAMERS.—The service of steamers on the river Thames, especially those for the beautiful up-river points, has hitherto, by universal consent, been most unsatisfactory. A new departure has now been made, and yesterday (Thursday) a large party of press representatives and others, under unfavourable weather conditions, proceeded from London to Hampton Court on the "Queen Elizabeth," a vessel drawing only 15 inches of water, and so constructed as to comfortably pass through all the locks up to Hampton Court. The builders, Messrs. Edwards and Co., of Millwall, are to be congratulated upon the handsome appearance of the boat, which has a promenade deck the entire length of the vessel (165 feet), and is installed with the electric light, fancy fittings being let into the panels of the saloons. A complete electric lighting plant has been supplied by Mr. W. Mackie, of Turnmill-street, London, E.C. The owner and manager, Mr. Edgar Shand, has exceptional experience of Thames river traffic, and it is to be hoped that his spirited endeavour to provide suitable craft for passenger and pleasure traffic may meet with such success as to warrant a speedy increase in the fleet of which the "Queen Elizabeth" is a promising example. Even in wet weather the "Queen Elizabeth" is a very comfortable boat.

WELLINGBOROUGH.—The installation of the electric light in the extensive sidings of the Midland Railway Company at Wellingborough, where the marshalling of all the coal traffic for London and the South is carried out, has now been completed. By means of the electric light work can now be performed with the same facility by night as in daylight, and with much less danger to the men employed.

WELLS.—Some time back an offer was made by Mr. A. Dixon Browne to light the public streets of Wells for a sum of £350 per annum for a period of three years. This proposal was approved by the Town Council, and a contract prepared for Mr. Browne's signature. There appears to be some hitch in the arrangements, and in a letter read at the last meeting of the Council it was suggested that, in order that the scheme of lighting the district electrically might be carried through, the appointment of another electrician might become necessary.

WEST COWES.—The District Council have received Mr. Medhurst's report on the proposed electric lighting of the district, and is to be considered at the next meeting.

WOLVERHAMPTON.—The report of the Lighting Committee, which is to be presented at the meeting of the Town Council on Monday next, states that the generating plant at the central station is now taxed to almost its utmost capacity, and, as the Council wish to make certain extensions, the Committee recommends that additional machinery be put down, and that application be made to the Local Government Board for sanction to borrow a further sum of £5,000 for this purpose.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

June 19, 1895.

11,944. C. RALEIGH. London. Improvements in the electrolytic deposition of metals and in means applicable therefor.

11,951. S. BERDITSCHEWSKY (called APOSTOLOFF). London. Improved system of telephonic exchange.

June 20, 1895.

11,973. C. B. CRAWSHAW and R. KENNEDY. Bradford. Improvements in lights and reflectors for photography by electric and other lamps.

11,976. H. W. HEADLAND. London. Improvements in electric safety lamps for use in mines and other places.

11,982. S. F. WALKER. Cardiff. Improvements in electromagnetic devices for automatically breaking the connections with the source of supply of electric light and power cables.

12,030. W. J. DAVY. London. Improvements in electric arc lamps.

12,035. T. J. PHIPPS. London. Mechanism for cutting off gas or electric current at any desired time.

12,042. W. JANDUS. London. Improvements in globes for arc lights for other lights of great intensity.

June 22, 1895.

12,157. J. L. BERNERS and F. GRIFFIN. London. Improvements in electric lighting, specially applicable for lighting vehicles.

12,161. A. J. MOULART. London. Improvements in apparatus for automatically indicating the fracture of electric conductors.*

June 24, 1895.

12,187. H. C. L. HOLDEN. Woolwich. Improvements in telephonic apparatus.

COMPANIES' MEETINGS AND REPORTS.

Electric and General Investment Company (Limited).

The sixth ordinary general meeting of the shareholders of this Company was held on Tuesday at Winchester House, under the presidency of Mr. George Herring.

The SECRETARY (Mr. J. Cecil Bull) read the notice calling the meeting.

The report having been taken as read, the CHAIRMAN said: The empty chairs tell me pretty plainly that the absent shareholders are perfectly satisfied with the report, and I have no intention of detaining those gentlemen who are present with a long speech. I will therefore at once proceed to the balance sheet. The first line on the left hand is the capital, and, as I have before explained, the smallness of the capital you have paid up is the cause of your large dividend. The reserve fund in connection with the Founders' shares I will speak of when I come to deal with the other side of the account. The reserve fund of the Ordinary shareholders still remains as before; and the item of "Provision for contingencies" we have left, for reasons we consider quite satisfactory, at £8,000. The loan account is increased to £26,790, and perhaps you will notice the reason for that by the footnote to the balance sheet. Last year there was a liability of £35,431, which is now reduced to £8,516. That partly accounts for the increased loan. The item of sundry creditors stands at £1,431. The balance of profit and loss account is £5,330, of which I will speak presently. On the other side of the balance sheet the entry "By investments at cost" is one upon which you naturally depend. I may say that the investments are stated at cost, not because we have not carefully gone over them and seen the valuations, but because we have determined not to be continually altering them according to the valuations, although we keep that point in our mind. I can tell you, however, that the £69,821. 8s. 2d. is absolutely good at the present moment. The sundry debtors are quite good; in fact, many of them have since paid. The item of cash in hand speaks for itself. The Founders' reserve fund is smaller by the amount of money on the other side—that is, by the dividends received and investments sold by trustees—£1,584. I shall have again to say a few words regarding the Founders' reserve fund, and therefore I will at this moment merely call attention to this alteration, and proceed to the profit and loss account. The first item there to which I will call your attention is the general charges, and, as I have before said, they increase with your profits, and you must grumble if you see the charges decrease, because that will mean that your profits are less. An interim dividend was paid to you last December at the rate of 10 per cent. per annum for the six months ended 30th November, and there is now a balance of £5,330, which we propose to divide in the manner stated in the report. We propose to pay to the Ordinary shareholders a dividend at the rate of 30 per cent. per annum for the past six months, and a dividend on the Founders' shares of £20 per share for the year. This will leave a balance of £330. 13s., which will be apportioned equally to the reserve funds of the Ordinary and Founders' shares. Now, with regard to the Founders' reserve fund I will say a few words. We invested it originally for the Founders, and in doing so we invested it, as we thought, in a proper and advantageous manner. Fortunately it has turned out to be even better invested than we had hoped for at the time, and therefore the Board and the Trustees thought that it was only a proper thing that some small part of the securities should be sold and be divided amongst the holders of the Founders' shares. Absent shareholders, as well as those present, must understand distinctly that all the stock of the Founders' reserve could have been sold if the Trustees had liked, but they only sold this portion in order to keep up the rate of dividend. I have no wish to discount or to prophesy regarding the future, but I think it only fair to tell you what the worth of your shares is at the present moment, and I can do that in a few words, so that you may see at once how you stand. Taking our word that the investments at cost price are worth the money, we find that we have the capital which you have paid intact, which we will call £1; the reserve fund, which we call another 10s.; and the provision for contingencies, which you may reckon as being about £5,000 for the Ordinary shareholders' reserve and £3,000 for the Founders' reserve, would give another 5s. a share, and in addition there is the present dividend of 3s. per share, so that altogether you have your Ordinary shares at this moment worth £1. 18s., *plus* the goodwill of the business, and it is for you to reckon what that is worth. We believe that the reserve fund, if cut up, would produce £140 to each of the holders of the Founders' shares. Their £5 of capital is intact; and taking at £30 a share their portion of the provision for contingencies we have £175 a share, in addition to the £35 16s. to be paid now. The Founders' shares are at this moment, therefore, worth absolutely £210 each, *plus* the goodwill of the business. I make these remarks because our shares are not dealt in on the Stock Exchange in the free manner that, for instance, Turkish stocks are dealt in, and therefore there is a general feeling—What is the worth of the shares? I have now told you what their value is at the present moment, irrespective of what the goodwill of the business may be worth. I do not know that I need detain you any further, but I shall be glad to answer any questions. I now propose—

"*That the report of the Directors and the statement of the accounts to May 31, 1895, with the appropriation of the surplus profits as proposed, be and the same are hereby received and adopted.*"

Mr. J. B. BRAITHWAITE, Junr., briefly expressed his pleasure in seconding the motion.

The resolution was carried unanimously.

The CHAIRMAN: I have now to propose—

"*That a dividend at the rate of 30 per cent. per annum for the half-year ended May 31, 1895—making, with the interim dividend at the rate of 10 per cent. per annum paid for the six months ended November 30, 1894, 20 per cent. for the year—be and is hereby declared on the capital paid up on the Ordinary shares, that a dividend of £20 per share be and is hereby declared on each Founder's share, and that the respective dividends be paid on July 3, 1895.*"

Mr. B. H. VAN TROMP seconded the motion, which was carried unanimously.

The CHAIRMAN: The Directors who retire are Lord Cloncurry and Mr. Braithwaite. Lord Cloncurry has found it necessary to remain in Ireland for the greater part of the year, and therefore wishes to retire. We have accepted his resignation with great regret, but we were compelled to do so. Mr. Braithwaite, the other retiring Director, offers himself for re-election. His abilities and devotion to your interests are so well known that it is not necessary for me to say anything further, and I therefore formally propose that he be re-elected.

The MANAGING DIRECTOR (Mr. Emile Garcke) seconded the resolution, which was unanimously agreed to.

On the motion of Mr. SYDNEY MORSE, Mr. George T. Rait was re-elected as auditor for the year ending May 31, 1896.

A cordial vote of thanks to the Chairman and Directors brought the meeting to a close.

India Rubber, Gutta Percha, and Telegraph Works Company (Limited).

A half-yearly general meeting of this Company was held on Thursday at Cannon-street Hotel, Mr. S. W. Silver presiding.

The SECRETARY (Mr. W. J. Tyler) read the notice calling the meeting.

The CHAIRMAN said: The occasion of calling you together to confirm the proposal just referred to in the notice calling the meeting affords an opportunity of reminding you that when we last met discouraging prospects of the trade of the country generally prevailed, and allusion was made to the caution necessary in opening accounts in order to avoid losses. This coupled with such keen competition as prevails on all sides, called for extra care and great efforts on the part of the staff and every one engaged, in order that the volume of business of this large and varied concern might not be diminished. Speaking generally, I may say the works, which are in first-rate order, at Silvertown and Persan, have been fairly well employed, with the exception of the submarine telegraph departments, in which we have no contract of importance to report. You doubtless are aware that our books are not made up until the end of the year. As a matter of prudence and precaution it is, in the judgment of the Directors, not judicious to pay a higher interim dividend than 2½ per cent. on the present occasion. With these few remarks I beg to move

"*That an interim dividend of 2½ per cent., or 5s. per share, free of income tax, payable on the 5th inst., be now declared.*"

Mr. ABRAHAM SCOTT seconded the resolution.

Mr. ROBERTSON asked if the shareholders might have a little further information with regard to the serious drop in the interim dividend from 10s. to 5s. per share. He thought that, at least, attention ought to have been called in the circular sent out to the reduction, instead of it being altogether ignored. The Board would probably have observed that some of the shareholders had been frightened by the announcement, and had been hurt in their interest. If anything of the sort should occur again he hoped the Board would give some explanation in the circular issued to the shareholders.

Capt. GRANT inquired if the Directors had any information to impart with reference to the Pacific cable.

Mr. WATSON wished to know if the reserve fund still stood at £450,000.

The CHAIRMAN, in reply, said: With regard to the circular issued to the shareholders calling this meeting, I may say that it has been in the same form from the commencement, and I do not think we shall alter it. (Mr. Robertson: "I hope you will.") The Pacific cable question remains unaltered. Yesterday's *Times*, I think, has a reference to it, but that is only a repetition of what we heard six months ago. It is in the hands of the Home and Colonial Governments. The reserve fund remains as it was.

The resolution was then agreed to unanimously.

Mr. TREBLE proposed a vote of thanks to the Chairman, which was carried.

The proceedings then terminated.

United River Plate Telephone Company (Limited).

The following report of the Directors of this Company for the year ended March 31st last will be presented at the ninth ordinary general meeting, to be held at Winchester House, Old Broad-street, E.C., on Tuesday next, at 12 o'clock:—

At par of exchange the Company's gross receipts for the year were £149,262. 2s. 9d., the working expenses in the River Plate £71,449. 9s. 3d., and the loss on exchange £58,693. 2s. 7d., leaving a profit, after the deduction of all charges, of £9,901. 15s., to which is added £6,417. 17s. 4d. brought forward, making a total of £16,319. 12s. 4d. The Directors propose to transfer to depreciation and renewal fund £3,000, and recommend that a dividend of 3 per cent. (free of income tax) be paid upon the

Digitized by Google

Ordinary share capital of the Company, and that the balance of £4,619. 12s. 4d. be carried forward.

The capital outlay for the year was £2,661. 16s., against £3,038. 5s. 8d. for the previous year. The plant has been maintained in good and efficient condition at the cost of revenue. There has been a continuous increase in the business of the Company, and the Directors trust that this improvement will be maintained in the future.

Mr. Frank W. Jones and Mr. Alfred Le Rossignol offer themselves for re-election as Directors, as do the auditors, Messrs. Cooper Brothers and Co.

NEW COMPANIES, STATUTORY RETURNS, &c.

CAPITAL AND COUNTIES ELECTRICITY SUPPLY COMPANY (LIMITED).—This Company was registered on June 28th, with a capital of £5,000, in £5 shares, to carry on the business of electric light contractors and makers and dealers in electrical plant and apparatus. The subscribers, with one share each, are: Edward Mann, electrician; F. Wright, C. E. Masterman, Percy Greville, electrician; A. Branch, electrician; W. E. Hanshaw, and Geoffrey New.

LIVERPOOL DISTRICT LIGHTING COMPANY (LIMITED).—This Company was registered on June 29th, with a capital of £2,000, in £5 shares, to carry on at Liverpool and its neighbourhood the business of an electric supply company in all its branches, electricians, mechanical and electrical engineers, suppliers of electricity for the purposes of light, heat and motive power, and manufacturers of and dealers in electrical apparatus and materials; to construct, lay down, establish, fix, and carry out all necessary cables wires, lines, accumulators, and works, and to carry on the business of a gasworks company. The subscribers, with one share each, are: J. Entwistle, H. J. Hale, W. Bartington, A. W. Cockeram, J. Cox, G. Hall, and J. Griffiths.

NEWMARKET ELECTRIC LIGHT COMPANY (LIMITED).—This Company was registered on June 27th, with a capital of £30,000, in £10 shares, to carry on at Newmarket, Suffolk, and neighbourhood, the business of electrical engineers, electricians, engineers and contractors, suppliers of electrical power, light and heat, manufacturers of and dealers in electrical and scientific apparatus, chemical engineers, and the general business of an electric light, heat and power supplying company. The subscribers, with one share each, are: T. Jennings, J. V. Lawrance, W. B. Sheppard, G. J. Jennings, B. Cuennell, A. Hughes, and E. H. Leach, all of Newmarket.

PINTSCH'S PATENT LIGHTING COMPANY (LIMITED).—This Company was registered on June 27th, with a capital of £60,000, in £5 shares, to carry on the business of lighting railway carriages, buoys, &c., with gas or other illuminating agency.

STANDARD ELECTRO-GALVANISING COMPANY (LIMITED).—This Company was registered on June 27th, with a capital of £4,000, in 3,500 Ordinary and 500 Deferred shares of £1 each, to purchase and work certain patents, &c., and to carry on the business of manufacturers and galvanisers of iron, steel, and other metals.

TOWN AND VILLAGE ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—This Company was registered on June 25th, with a capital of £100,000, in 19,800 Ordinary shares of £5 each and 1,000 Founders' shares of £1 each, to acquire and take over as a going concern the business of supplying electric light, heat and power, carried on by the Western Counties Electric Light and Power Syndicate (Limited), at Kingswood, Gloucestershire, and at Keynsham, Somersetshire, and carry into effect agreements made between George J. T. J. Parfitt and Edward B. A. James (acting for the Company), and between Harry Seymour Foster and the Company, and to carry on the business of undertaking the supply of electricity for light, heat, power and other purposes, electrical and mechanical engineers, electricians, and manufacturers of and dealers in all apparatus required for the generation, distribution, supply, accumulation and employment of electricity. The subscribers, with one share each, are: H. A. Tobias, H. E. Bailey, C. A. Mocatta, T. J. Woodrow, I. du Mont, C. F. Ince and L. H. Lemon. The first Directors are: F. B. Bond, W. Clifton, E. B. James and E. Casper.

ALTERNATE-CURRENT ELECTRO-MOTOR SYNDICATE (LIMITED).—An agreement, dated April 8th, made between Walter Langdon-Davies, engineer (the vendor), and George W. de Tunzelmann, electrical engineer (acting as trustee for the Company), provides for the sale to and purchase by the Company of the rights of the vendor as the inventor of certain improvements in electro-motors and similar electromagnetic apparatus having for their object the production of an approximately uniform rotating magnetic field suitable for working non-synchronous alternating-current motors, for which he has filed provisional specification and acquired provisional patent rights No. 19,364 of 1894. The consideration for the sale has been fixed at £2,500, payable £500 in cash and £2,000 by the allotment as fully paid of 2,000 shares of £1 each. The vendor has agreed to serve the Company at a salary of £400 per annum.

ANDREWS' FOREIGN SYNDICATE (LIMITED).—The statutory return, made up to May 6th, has been filed. The nominal capital is £4,000, in £1 shares. Of these 3,710 have been taken up, and 3,318 issued as fully paid to Joseph D. F. Andrews, electrical engineer, and John C. B. Andrews. The full amount has been called on the remaining 392 shares.

CITY NOTES.

CENTRAL LONDON RAILWAY.—Letters of allotment in the recent issue of the capital of this Company have been posted.

CHARING CROSS AND STRAND ELECTRICITY SUPPLY CORPORATION (LIMITED).—This Corporation makes payment of the half-yearly interest on the Five per Cent. Mortgage Debentures, due 1st inst., on and after that date.

CHELSEA ELECTRICITY SUPPLY COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend on the Six per Cent. Preference shares of the Company for the half-year ended June 30th. The dividend is payable July 18th.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended June 30th were £780, as against £1,020 in the corresponding week of 1894, being a decrease of £240. The total receipts for the half-year amount to £23,873, against £23,638 for the corresponding period of 1894, an increase of £235.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—The warrants for interest due July 1st on this Company's Five per Cent. Debenture Stock have been posted.

CONSOLIDATED TELEPHONE CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).—Mr. C. L. W. Fitzgerald presided yesterday (Thursday) over an extraordinary general meeting of the shareholders of this Company, when the resolutions relative to the modifications of and additions to the Articles of Association passed at the extraordinary general meeting of the Company held on June 6th last, were unanimously confirmed.

COVENTRY ELECTRICAL ENGINEERING COMPANY (LIMITED).—This Company has issued a prospectus inviting applications for 3,234 £1 shares. The Company was registered on September 11th last with an authorised capital of £5,000 in £1 shares, and carries on a general electrical engineering business. The lists opened on Monday last and closed yesterday (Thursday).

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of June, 1895, amounted to £1,884, as against £1,617 in the corresponding period of last year.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of June amounted to £58,500, and to £53,752 in the corresponding period of 1894, being on increase of £4,748.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of June, 1895, amounted to £36,679, and to £44,244 in the corresponding period of last year.

ELECTRIC AND GENERAL INVESTMENT COMPANY (LIMITED).—The warrants for the dividends, &c., recently declared by this Company, have been duly posted.

ELECTRICAL COMPANY (LIMITED).—We are asked to state that at the general meeting of this Company, on June 25th, Mr. F. T. Eggers was elected as Director. A resolution was passed by the Board appointing Mr. Eggers Managing Director. It was also decided that an important increase of capital will take place at the fall of the year.

INDIA-RUBBER, GUTTA-PERCHA AND TELEGRAPH WORKS COMPANY (LIMITED).—On the announcement of the greatly reduced interim dividend on the Ordinary shares of this Company, a fall in the shares from 21½—22½ to 17—19 took place. The *Financial News* is responsible for the following explanation:—"The reduction in the interim dividend of the India-Rubber and Gutta-Percha Company from 5 to 2½ per cent., which caused such a heavy fall in the shares last week, is not, we believe, due to any falling off in the Company's general business, but to a special reason. Tenders were invited some time ago for the new Pacific cable, and although nothing has yet been finally decided, the tender of the India-Rubber Company was the lowest, and has every prospect of being accepted. It is probably in order to retain as much cash in hand as possible, in case they get the contract for laying the cable, that the Directors have reduced the usual interim distribution; and, if this be so, shareholders need have no anxiety for the future." The closing price of the shares on Wednesday was 20—22.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 30th ult. amounted to £1,193. The amount for the corresponding week last year was £894; increase, £299.

NATIONAL TELEPHONE COMPANY (LIMITED).—The Directors of this Company, at their meeting yesterday (Thursday), resolved, subject to final audit, to recommend at the forthcoming general meeting of shareholders the following dividends (less income tax) for the half-year ended June 30th last:—At the rate of 6 per cent. per annum on the amounts paid up on the First and Second Preference shares, 5 per cent. per annum on the amounts paid up on the Third Preference shares, and 5 per cent. per annum on amounts paid up on the Ordinary shares, carrying £35,000 to reserve and about £3,000 forward. The transfer books of the Company will be closed from the 13th to the 26th inst. inclusive, and the dividend warrants will be posted on the latter date.

WEST AFRICAN TELEGRAPH COMPANY (LIMITED).—This Company gives notice of the annual drawing of Five per Cent. Mortgage Debentures, which will be paid off at par on September 2nd next at the National Bank of Scotland (Limited), Nicholas-lane, Lombard-street, E.C.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended June 28th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,552.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the half month ended June 30th were £1,854, as compared with £2,301 for the corresponding period of last year.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 895. [No. 11. Vol. XXXV.] FRIDAY, JULY 12, 1895. PRICE SIXPENCE.

NOTES.

In another column will be found a brief description of a large isolated plant recently laid down at Reading, the chief point of interest of which lies in the use, sanctioned by the Phœnix Fire Office, of iron piping. Instead of being run in the orthodox wood casing, the conductors from the main switchboard to the ceiling roses are encased in iron pipes.

The employment for a new purpose of what in the quaint language of the Patent Office would be termed an old "instrumentality" is always to be preferred to the adoption of any brand-new device answering the same end, provided, of course, the old instrumentality answers the purpose economically, mechanically and electrically at least equally well. The right place for the insulation of a house wire is on the wire itself, not on its protecting shield, the sole object of which should be to afford protection from mechanical injury, wet, fire, and the depredations of rodents. However, almost any form of conduit is better than wood casing, and it is therefore satisfactory to learn that the wiring of the new buildings now being erected on the grounds of the North-Western Hospital, Haverstock Hill, is also to be carried out on some conduit system. The tenders for this job have to be sent in by Thursday next, but, so far, the response to the advertisements has been meagre in the extreme. If, of course, one particular type of conduit had been specified, this result would have been expected. But as the contractor is left free to adopt any pattern within wide limits, it looks as if wood casing had more adherents than is warranted by the reason of things.

It is becoming increasingly difficult to vindicate any line of research from the charge of futility unless one can specify exactly in what its utility consists. The plea of the general utility of an extension of knowledge no longer avails. It is not enough to discover a way of attaining a certain end; the advantage—scientific or industrial—of reaching that end must be made plain. Tried by this standard, low temperature research is amply justified. In an address delivered some time ago before the Royal Institution, and reprinted in our present issue, Prof. Dewar marshals in formidable array the scientific fruit gathered by him when investigating the properties of bodies at the temperature of liquid atmospheric air, or thereabouts (−190°C.). Liquid oxygen is found to be very transparent to heat rays; the electrical conductivity of metals and alloys becomes exceedingly high; the optical properties of bodies are greatly modified; the elastic constants of metals are profoundly altered, there being for the most part a large increase in tenacity, although bismuth maintains its reputation for eccentricity, its breaking stress being reduced by 50 per cent. between 15°C. and −182°C. And now Prof. Dewar, in conjunction with Prof. Fleming, publishes a preliminary account of some low-temperature investigations on the thermo-electric properties of various pure metals and alloys. The experimenters propose to discuss their results in a further Paper, and we will therefore confine ourselves to pointing out the anomalous behaviour of our eccentric friend bismuth: at about −80°C. the thermo-electric curves of both pure and impure bismuth become discontinuous, bismuth behaving in regard to thermo-electric property at low temperatures in much the same way as does iron in regard to magnetic property at high temperatures. The final justification of low-temperature research, its industrial application, will no doubt come in due time; meanwhile this demonstration of its scientific utility will suffice for most of us.

A number of interesting experiments on the phenomena of electrostatic discharge have recently been undertaken by Mr. G. T. Hanchett, and are described by him in an article in the *Electrical World* of New York. Mr. Hanchett has found that when a uni-directional spark is passed between two tinfoil electrodes there is no appreciable loss of weight of the electrodes, even when weighed with a balance turning with 0·01 milligramme, although finely divided dust of tin was deposited symmetrically around the electrodes and in the spark gap. The dust must have been of an extremely finely divided nature in order to be apparent over so large an area, and yet to possess negligible weight. It is to be regretted that Mr. Hanchett does not appear to have employed any optical or other method of determining the thickness of the film. We would suggest also that oxidation of portions of the electrodes may possibly compensate to some extent for loss of weight, and thus make the latter seem negligible. The discharge exhibits two marked characteristics—a fine blue line and a hazy red line; but when only feeble discharges are passed the red line is not present. Increase of electrostatic capacity in the circuit has the effect of giving greater prominence to the blue line, and it gives a yellower tint to the red one. The author regards this as being in

Digitized by Google

curious disagreement with MAXWELL's formula, since the increased capacity of the circuit apparently produces a discharge of shorter luminous wave-length. This, however, is rather an unwarranted interpretation of MAXWELL's formula, which is intended to give, not the frequency of the spark light, but the frequency of the electrical oscillations.

PASSING an open street box in the City recently, we observed a couple of men engaged in removing a quantity of what appeared to be wood-paving blocks. The blocks had been placed inside the box in order to fill up space which might otherwise be occupied by an explosive mixture of gas; and they were apparently being removed in order that a joint might be made. The use of bulky solids in this way is an excellent expedient under the circumstances. Various materials have been proposed, from bags of sand to blocks of timber; but the use of all of them entails considerable increase in the labour and time of opening up a street box. Bulk, not weight, is the chief desideratum. Timber blocks no doubt answer the purpose sufficiently well, the only conceivable objection to them being the possibility of their becoming ignited in the remote event of a gas explosion. But it would seem advisable to string the blocks together, so that they may easily be drawn out, rather than to have them separate, as is now the case. Metal, were it not so heavy, would be the best thing to use, as its high thermal conductivity would prolong an explosion into a safe and mild temporary combustion.

IT is well known that in the case of some substances which are poisonous in small quantities, a very much larger dose will prove its own antidote; but it has been left to a Belgian Viscount to apply this principle to secondary batteries. In the old days the great drawback to pasted plates was the liability of the peroxide to flake off and form a connection between the two plates, with consequent detriment to the cell; and much trouble and ingenuity have been expended to render short-circuiting from this cause well-nigh impossible. In Belgium, however, they are about to order things differently; that is, if the Viscount can have his way. He has discovered that oxides in general, and peroxide of lead in particular, have no specific conductivity, and that if they conduct the current when used in a cell, it is only due to the liquid in which they are immersed. Utilising this discovery, he reduces the internal resistance to a minimum by placing the negative electrodes in direct contact with the peroxide without the interposition of any insulator whatever. The inventor states that the only care which need be taken in the setting up of this exceedingly simple and compact cell is to avoid any purely metallic connection between the positive and negative electrodes. There is a delightful simplicity about the construction of this cell which, we make no doubt, will be as much appreciated by our readers as by ourselves.

Cable Interruptions.—There are no cable interruptions to report this week.

Budapest Tramway Company.—The Municipal Committee of Budapest has renewed the contract with the Tramway Company for 50 years, on the condition that by 1898 all the lines are electrically equipped.

Copper Market.—According to Messrs. Merton and Co.'s statistics the visible supply of copper on June 30th was 58,182 tons, as against 50,072 tons on June 30, 1894, and 49,955 tons on June 30, 1893.

Central London Railway.—The Directors of the Central London Railway have instructed their engineers (Sir John Fowler, Sir Benjamin Baker, and Mr. Greathead) to proceed at once with the work.

Telephonic Communication in Java.—A company has just been formed in Batavia with a capital of 33,000fl., to be known as the Telefoon Maatschappij Buitenzorg, to establish and operate a telephone exchange at Buitenzorg.

Municipal Telephony in Amsterdam.—In view of the fact that the concession granted to the Bell Company for the operation of the telephone exchange in Amsterdam shortly expires, the municipal authorities have lately decided to carry on the same as a municipal undertaking.

"The Engineer" Road Carriage Competition.—Our esteemed contemporary the *Engineer* is offering a prize of one thousand guineas, in two or more prizes, for a public competition upon one of the main roads of the kingdom, of mechanically propelled vehicles. Further particulars are promised later.

The Lagrange-Hoho Process.—A practical demonstration of the Lagrange-Hoho process for the electrical treatment of metals was lately given at the central electric lighting station in Fribourg. A company is, it is stated, being formed to acquire and exploit the Swiss patents of the process.

Relative Merits of Cable and Electric Traction.—In speaking of the relative economy of cable and electric traction, Mr. McCulloch, general manager of the National Railway of St. Louis, is of the opinion that where a line earns only £10 a day per mile of single track, it is more economical to operate by electricity, but at £20 per day per mile the cable is the cheaper.

Drilling a Gas Well by Electric Motor.—The Westinghouse Electric Company will begin this week the drilling of a well for natural gas on the land in front of its new works at East Pittsburg, and the novel experiment of using electricity for power will be made. An ordinary 25 H.P. motor, such as is used in a traction car, will be placed in the engine house instead of a steam engine, and the electricity will be supplied from the works.

Electric Traction on Branch Railways in America.—According to *Engineering* the Pennsylvania Railroad Company, finding some of their branch lines financial failures, have introduced electric traction to try and render them remunerative. The first of these branches to be so worked is the Mount Holly line, which is about seven miles in length. In some preliminary experiments a speed of 42 miles per hour was obtained with a trolley car on this line, and with two standard cars attached a speed of 30 miles per hour was reached.

Accumulators at the Paris Central Telegraph Office.—Up to 1892 the work of the Paris central telegraph office required no less than 10,000 large Callaud cells. In that year, however, more than 3,000 of these cells were replaced by two batteries of accumulators. These accumulators have given such satisfaction that it is now proposed to suppress primary batteries altogether, and to instal a further batch of accumulators. The accumulators at present in use consist of a 50 cell battery of 60 ampere-hour Laurent-Cely cells, and a 60-cell battery of 72 ampere-hour Tudor cells.

Damage by Lightning.—On Tuesday last week a ploughman was driving from Lochearn Head Station, when he was struck by lightning and killed. The horse was also thrown down, but recovered.—At Wednesbury, on Saturday last, a young lad, aged 16, was killed by lightning while running across a field.—During a thunderstorm in Southern Sweden on Monday last week a shed, in which nine men and five women had taken shelter, was struck by lightning. Eight of the men were killed on the spot, while the shed was destroyed by fire. Those not killed were seriously injured.

Curious Accident in a Canadian Power House.—According to the *Canadian Electrical News*, an unfortunate accident occurred at the power house of the Toronto Railway Company some short time ago. The electrician in charge of the new Siemens-

Digitized by Google

Halske generator undertook to scrape the machine with a knife. The result was that the knife was drawn in and the armature short-circuited; the machine was badly damaged and severely burned the attendant. The accident threw on to the generator of the Canadian General Electric Company so great a strain that it broke down. Traffic on the street railway was for a short time stopped, and during repairs there was some restriction in the number of cars running. The Siemens-Halske machine had not passed out of the hands of the electrician of the firm, who was making the usual tests, when the accident occurred.

Report of the Select Committee on the Telephone Service.—The following is the text of the report of the Select Committee appointed to consider and report whether the provision now made for the telephone service in local areas is adequate; and whether it is expedient to supplement or improve this provision either by the granting of licences to Local Authorities or otherwise:—"Your Committee have examined numerous witnesses upon the matter referred to them, and have completed their evidence, but have not, in view of the approaching dissolution of Parliament, had sufficient time to consider their report. They have therefore agreed to report the evidence they have taken to the House, and to recommend that a Committee on the same subject be appointed in the next Session of Parliament, to consider and report upon the evidence already taken, and, if necessary, to take further evidence.—June 25, 1895."

Obituary.—The death is announced of Mr. J. B. Stearns, who died at Camden, Maine, U.S.A., on the 5th inst., aged 65 years. Mr. Stearns will be chiefly remembered in connection with the practical application of the duplex system of signalling. He showed how capacity could be added to the artificial circuit by means of condensers in such a way as to successfully balance the static capacity of the line. This made the duplex system practical and workable. He visited this country in the early seventies, and the result was the adoption by the Post Office in 1873 of his system of balancing. By means of this system the Department was enabled to work long circuits as duplex circuits, whereas before it had only been possible to apply duplex working to short lines having small capacity.——Rear Admiral Arthur Cecil Curtis, who suddenly expired at Spithead on Wednesday in a boat when returning from a visit to some of the vessels of the Italian fleet, was senior lieutenant of H.M.S. "Terrible," when that vessel took part in the Atlantic cable expedition of 1866, and he was promoted to the post of commander for his services in this connection.

Magnetic Observations.—In the report of the Astronomer Royal to the Board of Visitors of the Royal Observatory, which was read at the annual visitation, it is stated that the variations of magnetic declination, horizontal force and vertical force, and of earth currents have been registered photographically, and accompanying eye observations of absolute declination, horizontal force, and dip, have been made as in former years. Increased magnetic activity was shown in the year 1894, and great disturbances occurred on July 20th and August 20th; the spot of light of the vertical force magnet on the former date, and the spots of light of the horizontal force and vertical force magnets on the latter, having passed beyond the range of the registering sheets for some hours. In July and August the disturbances in the earth-current registers caused by the South London Electric Railway showed a great increase, which is presumably due to the experiments then being made in the use of motors on the carriages of the railway instead of separate locomotives. In the year 1894 there were 10 days of great magnetic disturbance and 13 other days of lesser disturbance. Tracings of the photographic curves for all of these days are being made, and will be published in the annual volume according to the arrangements made with M. Mascart.

Electric Traction for Milan.—As we announced in our issue of June 21st, the Town Council of Milan has entered into a contract with the Italian Edison Company by which the entire tramway service will be transferred to that Company on January 1, 1897. According to the *Frankfurter Zeitung*, this Company a short time ago received a concession from the Italian Government which enables it to employ water of the Adda—the outflow of Lake Como—to the extent of 24,000 H.P. This power the Company intends to transmit to Milan, a distance of about 22 miles, and several adjacent towns for lighting and power purposes. The conditions of the tramway contract are as follow:—The town undertakes to build and equip the lines and purchases all the materials and plant at its own expense, for which purpose a loan of 3,000,000 lire (£120,000) will be taken up. The town pay the Company for the working of the line 0·287 lire per car kilometre about 4½d. per car mile. The cars are to run 18 hours per day, from 6 a.m. till midnight. The town is to take 55 per cent. of the gross receipts and the Company 45 per cent. The system employed to be that of overhead conductors, as already put down by the Edison Company on a trial line 1·5 mile long.

The Electric Supply of the Dresden Railway Stations.—The novel feature of this plant is the up and down transformation of the "drehstrom" current, which is generated at 150 volts, transformed up to 3,100 volts, transmitted to the various railway stations and repairing shops, and transformed down again for lighting and power purposes. The plant consists of four 200-kilowatt Siemens "drehstrom" machines, coupled direct to horizontal tandem and compound engines running at 100 revolutions. The alternators have 60 poles and, therefore, a periodicity of 100 per second. The alternators feed on to three omnibus bars. For parallel running, electrical devices are provided on the governors of the steam engines which enable the speed to be regulated. A small motor moves the balance weight of the governor, and a switch on the main switchboard controls the action of this motor, and so allows the speed of the engine to be altered at will. In this way, two machines can be put in parallel without the assistance of resistances or an artificial load by simply influencing the governors of the two engines. The main current is taken from the omnibus bars to the transformer room, which comprises at present nine 100-kilowatt "drehstrom" step-up transformers, whence it is taken away by underground triplex cables. From a tower about 50 yards away run bare overhead conductors, which are then employed throughout the whole system.

Spherical Reflecting Globes for Arc Lights.—In a recent number of *L'Electricien* M. Albert Nodon relates a curious episode which occurred at Havre in connection with two Brianne arc lamps, which lighted a jeweller's shop front. These lamps were variable focus lamps, and were run two in parallel off the secondary of a transformer giving 60 volts, impedance coils being placed in series with each lamp. The carbons were placed inside a large glass globe, the hemisphere which faced the street being silvered inside and frosted out, so as to keep the light from the eyes of the passers by and reflect it back into the shop windows. As soon as the lamps were started running it was noticed that they went out regularly at intervals of about half an hour for an instant or so. On investigating the matter several small pieces of carbon about 4cm. long, cratered at one end and pointed at the other, were found at the bottom of the globe, and on further examination afforded an explanation of the extinction of the lights. The arc, in fact, when struck usually occupied a point somewhat above the horizontal diameter of the globe. A conjugate focus was formed at the corresponding distance below the horizontal diameter, with the result that the greater portion of the luminous and heat rays from the arc were concentrated upon the lower carbon, which soon became red hot at that point and then began to burn away, a process which was hastened by the increased heating effect of the current due to the increased resistance of the carbon at this point. The carbon was soon eaten away, and fell to the bottom of the globe; the mechanism of the lamp then brought the upper carbon into contact with the lower; the arc was struck below the horizontal diameter of the globe, and a conjugate focus of the arc was formed at a corresponding point above, with the result that the upper carbon was then eaten away in a similar manner, and so on. The difficulty was got over by doing away with the spherical globes, and replacing them by cylindrical reflectors of parabolic shape.

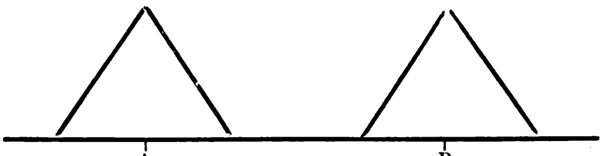
ELECTROMAGNETIC THEORY.—LXXI.*

BY OLIVER HEAVISIDE.

(*Continued from page 253.*)

§ 276. Imagine any wave form to be transmitted at a constant speed undeformed, as, for instance, a hump running along a flexible cord. Let it be as in the figure, namely, a triangular hump whose position at the moment of time $t=0$ is A, and at some later time t is B. It is to be imagined to travel at uniform speed v from left to right, so that the distance AB is vt, increasing uniformly with the time. If the base line is the axis of x, the travelling form is our "function of x," its value being the ordinate of the wave form.



Let $f(x)$ represent the function when at A, and let it become $F(x)$ at B. They only differ in the change of origin. Their relation to one another is

$$F(x)=f(x-vt); \tag{77}$$

that is, the value of F at x at the moment t is, by definition, the same as the value of f at a distance vt to the left. Equation (77) expresses the characteristic property of an undistorted and unattenuated wave when the speed is constant. It is a positive wave. When it goes the other way, it is a negative wave, and the *minus* sign must be changed to *plus*.

Differentiate equation (77) with respect to x and t separately and compare them. We see that

$$\frac{dF}{dx}=-\frac{1}{v}\frac{dF}{dt}. \tag{78}$$

This is the characteristic partial differential equation of a solitary undistorted wave. It is easily understood by watching the transit of a particular part of the wave past a fixed point, and considering how the speed v of transit combined with the slope determines the time rate of increase of F at the fixed spot. Equations (78) and (77) have practically the same meaning. Thus, given (78), its solution is (77), understanding that f expresses an arbitrary function of x.

Now write (78) in the form

$$\frac{dF}{dt}=-v\Delta F, \tag{79}$$

where Δ stands for d/dx, and solve it as an ordinary linear equation. This makes

$$F=\epsilon^{-vt\Delta}f, \tag{80}$$

where f is a constant with respect to t. In our present case it is any function of x. That (80) is the solution is verifiable by its satisfying (79). What f is may be seen by putting $t=0$. Then $F=f$. So f is the initial state of F, and is therefore the same as the former f. Comparing (80) with (77), we see that the operator $\epsilon^{-vt\Delta}$ is the translation operator, so that

$$\epsilon^{-vt\Delta}f(x)=f(x-vt). \tag{81}$$

This is the universal property of the operator $\epsilon^{h\Delta}$ when h is a constant. What it does, when applied to a function of x, is to translate it bodily through the distance h to the left.

Applying (81) to the result (76) which gave rise to these remarks about uniform motion of a function, we found that a certain F series, when considered to exist only on the positive side of the origin, was identical with

$$(1-x/l)2(+\epsilon^{-2l\Delta}+\epsilon^{-4l\Delta}+\epsilon^{-6l\Delta}+\ldots)1, \tag{82}$$

where the operand 1 is only positively existent. Denoting this operand by $f(x)$, the auxiliary terms in (82) are equivalent to

$$2f(x-2l)+2f(x-4l)+2f(x-6l)+\ldots \tag{83}$$

The value of every one of these functions is 2 when it exists. But the first one only begins to exist when x reaches $2l$, the next when x reaches $4l$, and so on. The result is that the constant 2 is added on every time the variable x passes the points $x=2l$, $4l$, $6l$, &c. The function $(1-x/l)$ therefore, which falls down to -1 when $x=2l$, and which would by itself go on decreasing to $-\infty$, is lifted up by the first auxiliary to its starting value $+1$. The same series of values are then repeated between $x=2l$ and $4l$. Then the second auxiliary begins and lifts up the function to its initial value for another repetition. The F. series therefore represents $(1-x/l)$ between 0 and $2l$, followed by unending repetitions of the same series of values of the function.

If we allow the F series to exist on the negative side also, it is sufficient to note that it is an odd function of x, to see its nature there. The negative side may be done operationally by itself by ignoring the part already done, and reckoning x positively the other way; but this is quite unnecessary, since the work has been already done equivalently on the positive side.

Equation (81), or, which is the same,

$$\epsilon^{h\Delta}f(x)=f(x+h), \tag{84}$$

is the well-known so-called "symbolical" form of Taylor's theorem. For it is merely the condensation of the form obtained by expanding the exponential, viz.:

$$\left\{1+h\Delta+\frac{(h\Delta)^2}{\underline{|2}}+\frac{(h\Delta)^3}{\underline{|3}}+\ldots\right\}f(x)=f(x+h). \tag{85}$$

The form (84) is much more convenient. It is the form that always occurs naturally in operational mathematics. That is, we get solutions of the form $\epsilon^{h\Delta}$ acting upon something or other, and the meaning is simply a bodily translation performed upon it.

The way followed above is not the usual way of leading to Taylor's theorem, for which see works on the Calculus. It is a quasi-physical way, by which its truth becomes obvious in a general sense. It only involves the idea of translation of a form so far as the essential part goes. But now comes the question of failures. In fact, the proofs of Taylor's theorem are largely devoted to the discussion of modified forms with remainders occurring when there is some discontinuity, involving an infinite differential coefficient. When mathematicians come to an infinity they are nonplussed, and hedge round it. They would, for example, stick at the three sharp corners in the function above used, which involve discontinuity in the slope, or infinite curvature.

But there is no difficulty of the kind in the physical way of looking at the matter, so far as the act of bodily translation is concerned. One shape of the function is just as easily conceived as another, and we are not limited to the angelically perfect function which is finite and continuous itself, and has all its derivatives finite and continuous. It was long ago remarked by Sir G. Stokes that it is important for physical mathematicians to conceive of functions wholly apart from their possible symbolical expression. The remark is particularly important in the discussion of waves and their propagation, when discontinuous functions have frequently to be dealt with.

Now (77) is unexceptionable, and requires no special interpretation involving infinities. If $f(x)$ makes a jump suddenly at any place, so does $F(x)$ precisely at a corresponding place. But (78), which is taken to be equivalent to (77), inasmuch as it utilises differential coefficients, may require interpretation. We should not say that the whole thing breaks down if the slope is infinite, because (78) becomes meaningless. It requires interpretation, but is not uninterpretable. The variations in dF/dx and those in dF/dt keep pace together precisely, and this tie does not break when they are momentarily infinite.

Although, of course, in a popular sense, infinities are immeasurable, they are not necessarily unmeasurable. A suitable standard is required to measure an infinity. Consider, for example, the case of electrification. Starting with a finite volume density, if we imagine it condensed on a surface, we have infinite volume density. But that causes no trouble. It is now to be measured by its surface density. Again, imagine it condensed from finite surface electrification to linear elec-

* This series of articles is a portion of Vol. II. of Mr. Heaviside's work on "Electromagnetic Theory." All rights of reproduction are reserved.

Digitized by Google

trification. This means infinite surface density, and therefore doubly infinite volume density. But we now have a finite linear density, so there is no difficulty in measurement, or at any rate in the conception of the suitable way of measuring. Again, the notion of impulses in dynamics is exceedingly useful, though it involves the idea of an infinite force. We must not be afraid of infinity. If suitably measured, it may be no bigger than zero, or else quite small.

Now I think that similar ideas may with advantage be introduced into pure mathematics, to enlarge the scope of the mathematicians' investigations, and enable them to tackle infinities, instead of evading them. However, we are not concerned with the real or supposed failures in Taylor's theorem, perhaps rather to be considered failures in the mathematical machinery. In the operational mathematics $\epsilon^{h\Delta}$ is the translational operator, no matter how many discontinuities may be in the way. We do not have to consider the infinite values, but just jump over.

In physical applications, say to waves, the subject of operation is real and single valued, though it need not be finite and continuous. But I do not see any reason why the translational idea should not be carried further. Let it be applied to any definite series of values, or of multiple values, or perhaps to the case of a multiple pole, involving a collection of infinities.

§ 277. Since the investigation in § 275 shows one the working of the inner mechanism of a Fourier series in an interesting way, it will be worth while to consider another example of the same sort. We may put it thus :—

$$\coth l\Delta \,.\, f(x) = (1 + 2\epsilon^{-2l\Delta} + 2\epsilon^{-4l\Delta} + \dots)f(x) \qquad (86)$$

$$= \left\{\frac{1}{l\Delta} + \sum_1^\infty \frac{2/l\Delta}{1+(n\pi/l\Delta)^2}\right\}f(x); \qquad (87)$$

and if we like to confine ourselves to the region 0 to $2l$, we may omit the translational auxiliaries, and write

$$f(x) = \left\{\frac{1}{l\Delta} + \sum_1^\infty \frac{2/l\Delta}{1+(n\pi/l\Delta)^2}\right\}f(x). \qquad (88)$$

Take $f(x) = 1$ to make up the expansion of $1 - x/l$ considered in § 275.

Next take $f(x) = x$. Then (88) becomes

$$x = \frac{x^2}{2l} + \sum_1^\infty \frac{2l/(l\Delta)^2}{1+(n\pi/l\Delta)^2}, \qquad (89)$$

since $x = \Delta^{-1}1$, $\frac{1}{2}x^2 = \Delta^{-2}1$. Continuing the algebrisation we obtain

$$x = \frac{x^2}{2l} + \sum_1^\infty \frac{2}{n^2\pi^2}\left(1 - \cos\frac{n\pi x}{l}\right); \qquad (90)$$

or, which is the same,

$$x = \frac{x^2}{2l} + \frac{1}{3} - \sum_1^\infty \frac{2}{n^2\pi^2}\cos\frac{n\pi x}{l}. \qquad (91)$$

This is true between $x = 0$ and $2l$.

But the full meaning, according to (86), (87), including the auxiliaries, is

$$\sum_1^\infty \frac{2}{n^2\pi^2}\cos\frac{n\pi x}{l} = \left(\frac{x^2}{2l^2} - \frac{x}{l} + \frac{1}{3}\right) - \frac{2}{l}[x - 2l] - \frac{2}{l}[x - 4l] - \dots, \qquad (92)$$

where the terms with square brackets are the auxiliaries. They are to be understood in this way. In (86), $f(x)$ is to be x, so the auxiliary functions (not doubled) are $f(x - 2l)$, $f(x - 4l)$, &c., and these are the same as $x - 2l$, $x - 4l$, &c., when they exist. Now $f(x)$ is born when $x = 0$, and is positively existent. So $f(x - 2l)$ is born when $x = 2l$, and so on. The final result is simple enough, namely, that in (92), with a particular value of x, just as many of the auxiliaries exist as have positive values. The rest are not yet born ; they are zero.

In the region $x = 0$ to $2l$ we have the curve

$$y = \frac{x^2}{2l^2} - \frac{x}{l} + \frac{1}{3}. \qquad (93)$$

The ordinate y is $\frac{1}{3}$ at $x = 0$ and $2l$, and has its minimum, namely $-\frac{1}{6}$, midway between. After $x = 2l$, it would rise up to infinity by itself, but the first auxiliary is now existent. Adding it on, we get

$$y = \frac{x^2}{2l^2} - \frac{3x}{l} + \frac{13}{3}. \qquad (94)$$

This is the same as

$$y = \frac{(x-2l)^2}{2l^2} - \frac{(x-2l)}{l} + \frac{1}{3}. \qquad (95)$$

Comparing the last with (93), we see that they have the same form, only x in (93) becomes $x - 2l$ in (95). So the values of y between $x = 0$ and $2l$ repeat themselves between $x = 2l$ and $x = 4l$. Then the second auxiliary comes into play, and causes another repetition of the same series of values of y. And so on to infinity.

The above refers to the positive side of the x axis. On the negative side we see the meaning of the Fourier series by observing that it is an even function of x.

The reader who is curious in this matter will find it useful to treat various simple Fourier series in the manner of § 275, to discover their meaning. Thus, given

$$f(x) = A_0 + \sum_1^\infty A_n \cos\frac{n\pi x}{l} + \sum_1^\infty B_n \sin\frac{n\pi x}{l}. \qquad (96)$$

This may be converted at sight to

$$f(x) = A_0 + \sum_1^\infty \frac{A_n}{1 + (n\pi/l\Delta)^2} + \sum_1^\infty \frac{B_n(n\pi/l\Delta)}{1 + (n\pi/l\Delta)^2} \qquad (97)$$

by the use of (73) and its cosine companion formula. Now sum up the partial fractions, if you can. The coefficients are supposed to be known functions of n. The summations may be effected by the formulæ for the expansion of $\coth l\Delta$, $(\text{shin}\, l\Delta)^{-1}$, &c., in partial fractions, or by formulæ derivable from them. When this is done, comes another important step. The trigonometrical functions of $l\Delta$ may be expressed in series exponentially (*e.g.*, like $\epsilon^{-2l\Delta}$, &c.), and then Taylor's theorem, in its general translational sense, comes into play, and the full meaning of the F. series becomes evident. We determine it to represent a certain function between certain limits, and endless repetitions of the same values caused by the existence of the auxiliary terms involving the translational operators. The example in § 275 is fully descriptive in a general way, combined with the explanation in § 276, and the application may be made to a variety of formulæ. But the method is not meant for general use, because the summation of the partial fractions may be a troublesome matter.

The question arises whether a Fourier series with its constants given numerically can be done in the same way. Probably it can, or by some extension of the process. But it may be necessary to discover first the law followed by the coefficients, so that they may be regarded as functions of n.

§ 278. By equation (86), we see that the operator $\coth l\Delta$, applied to a positively existent function of x, turns it into the sum of $f(x)$ and of twice the sum of its values at the points $x - 2l$, $x - 4l$, &c.

From this, we conclude that if $f(x)$ exists only between 0 and $2l$, meaning thereby that it is zero outside those limits, the series $\coth l\Delta \,.\, f(x)$, as in (86), represents $f(x)$ first, in its proper place, and then an infinite series of repetitions of the values of the same function doubled. For example, if $f(x)$ is x^2, we get first x^2, next $2(x - 2l)^2$, then $2(x - 4l)^2$, and so on, in regions of length $2l$, every one by itself.

Therefore

$$(\tfrac{1}{2} + \tfrac{1}{2}\coth l\Delta)\mathrm{I}f(x) \qquad (98)$$

represents $f(x)$ and periodic repetitions of the same (not doubled), from $x = 0$ to ∞, still understanding that $f(x)$ is zero except between 0 and $2l$.

And by a slight extension we see that if

$$\mathrm{F}(x) = (1 + \epsilon^{-2l\Delta} + \epsilon^{-4l\Delta} + \dots + \epsilon^{2l\Delta} + \epsilon^{4l\Delta} + \dots)f(x), \qquad (99)$$

then $\mathrm{F}(x)$ represents $f(x)$ and periodic repetitions to right and left through the whole range of x from negative to positive infinity. Only one term exists (or is finite) at a time. But if $f(x)$ be so chosen that its initial and final values do not agree, there is a jump in the manner before alluded to. The periodic property $\mathrm{F}(x + 2l) = \mathrm{F}(x)$ is momentarily violated, unless we represent the vertical part of the curve by the mean value.

Now, the reader may amuse himself by considering the exponential expansions of other trigonometrical functions of a differentiator, as than $l\Delta$, and the reciprocals of shin $l\Delta$ and

Digitized by Google

cosh $l\Delta$, and their powers as operators on a function. It will be sufficient here to derive Fourier's theorem in its general form from the above.

Go back to (99). By construction the series $F(x)$ has the same meaning as Fourier's

$$F(x)=\int_0^{2l} uF(y)dy, \qquad (100)$$

where

$$u=\frac{1}{2l}\left(1+2\Sigma_1^\infty \cos\frac{n\pi(y-x)}{l}\right). \qquad (101)$$

Here u is expressive of a unit impulse at the points $x\pm 2nl$, as before explained, and (100) shows how a single value of the function is isolated.

Now $\Delta 1$ is a unit impulse at the origin of the variable. Let the variable be $y-x$. Then $\Delta 1$ signifies a unit impulse at point $y=x$, and nothing anywhere else. So, by (99), we have

$$u=(1+\epsilon^{-2l\Delta}+\epsilon^{-4l\Delta}+\ldots+\epsilon^{2l\Delta}+\epsilon^{4l\Delta}+\ldots)\Delta 1. \qquad (102)$$

Since, by construction, this u represents the periodic unit impulse, like (101), we see that (102) must be the operational form of (101) itself.

But to algebrise (102) it is convenient to consider the positive and negative regions separately. Split u into halves, thus :—

$$u_1=\tfrac{1}{2}(1+2\epsilon^{-2l\Delta}+2\epsilon^{-4l\Delta}+\ldots), \qquad (103)$$

$$u_2=\tfrac{1}{2}(1+2\epsilon^{2l\Delta}+2\epsilon^{4l\Delta}+\ldots), \qquad (104)$$

Here u_1 is for the positive side, and u_2 for the negative, u_1 meaning half a unit impulse at the origin $y=x$, and whole ones at $y=x+2l$, $x+4l$, &c.; whilst u_2 means half a unit impulse at $y=x$, and whole ones at $x-2l$, $x-4l$, &c.

Now (103) is equivalent to

$$u_1=\frac{1}{2l}\coth l\Delta \,.\, l\Delta. \qquad (105)$$

This is equivalent in partial fractions to

$$u_1=\frac{1}{2l}\left\{1+\frac{2}{1+(\pi/l\Delta)^2}+\frac{2}{1+(2\pi/l\Delta)^2}+\ldots\right\}. \qquad (106)$$

Finally, the algebrisation is immediate, making

$$u_1=\frac{1}{2l}\left\{1+2\cos\frac{\pi}{l}(y-x)+2\cos\frac{2\pi}{l}(y-x)+\ldots\right\}. \qquad (107)$$

This result shows the same expression identically as Fourier's u in (101). But it has not the same meaning. Remember the reservation that $y-x$ ranges from 0 to ∞ only in connection with u_1. In (105), (106) the positively existent unit operand is understood. So (107) is limited to the positive side.

Similarly, from the symmetry of the complete u in (102) with respect to the origin $y=x$, or by reckoning $y-x$ positively the other way, so that u_2 is represented formally by u_1, we find that u_2 is given by the same expression (107) as u_1. Only in this case y has to be not greater than x.

So, removing the restriction, we see that the sum of u_1 and u_2 has the same expression as either. No change is needed in the trigonometrical formula because it is an even function of $y-x$. In its use to represent u_1 or u_2 alone, we merely restrict the range of its application. When unrestricted, we find that the u of (101) means the same as that in (102), the impulse periodic both ways.

It seems somewhat unnatural to consider the right and left halves separately. And yet it is necessary. This becomes evident at a discontinuity. Suppose $f(y)$ is zero on the left side of $y=x$, and finite instantly on the right side. Evidently u_2 is inoperative, and u_1 alone works. It gives only $\frac{1}{2}f(x)$, that is $\frac{1}{2}$ the value on the right side.

Again, if at $y=x$, the function is A on the left and B on the right side, u_1 will give $\frac{1}{2}$B, and u_2 will give $\frac{1}{2}$A. The complete u will therefore spot the mean value.

Poisson's demonstration is interesting in this connection. Instead of u he used the function

$$v=\frac{1}{2l}\left\{1+2\Sigma_1^\infty h^n \cos\frac{n\pi(y-x)}{l}\right\}. \qquad (99)$$

It becomes the same as u when $h=1$. Now when h is <1, this v function is continuous. Its total between 0 and $2l$ is 1, and it has a hump at the point $y=x$. The closer h is made to approach to unity, the more the v function is heaped up at and close round the point $y=x$. In the limit it is all there, like u. Now the curve of v is symmetrical with respect to $y=x$; half its area is on one side, and half on the other. So, if h is very close to 1, and we use v in the formula (91) instead of u_1, we shall obtain $\frac{1}{2}$(A+B) approximately, and the more closely we make h approach unity the closer the approximation. I know no reason why a failure should occur just as perfection is reached.

(To be continued.)

NOTES ON SOME EXPERIMENTS WITH ELECTRO-MAGNETIC MECHANISM.

BY P. V. McMAHON.

(Continued from page 293.)

The next group of experiments was made with the same coil, and under similar conditions with cores Nos. 2, 3, 4 and 5, each core being 15·5in. long, $\frac{2}{3}\frac{2}{2}$in. diameter. No. 2 had both ends cylindrical, No. 3 had the top end tapered for a distance of 2in., No. 4 the top end tapered 6in., and No. 5 both top and bottom ends tapered 6in. (*see* Fig. 3). A set of observations was obtained for each core (*see* Figs. 5, 6 and 7), with different weights attached, and the travel and variation of ampere turns plotted as before. It is noticeable from these curves that their general shape is very similar, but the travel is shorter as the weight is increased for the same variation of ampere turns. Thus, with the cylindrical-ended core light the travel for 5,000 ampere turns variation is 2·3in.; with 35oz. weight attached the travel is 1·9in. for the same variation of exciting power; increasing the weight to 52oz. the travel is further reduced to 1·5in. for 5,000 ampere turns variation. The same reduction of travel is obtained with the other three cores for an increase of weight, except in the case of the double-tapered core without a weight; here the travel is 2·25in. for a variation of 5,000 ampere turns. With 35oz. added to core the travel is 3·2in. for same exciting power; increasing the weight to 52oz. the travel is reduced to 2·55in. for 5,000 ampere turns variation. This difference in behaviour is probably due to the core being so much lighter, on account of the bottom end being tapered, that it was drawn into the coil much more than in the other cases with the lowest excitation. In fact, comparing it with the core tapered 6in. at the top end, we can plainly see from the curves that the latter core point was 0·5in. below and inside the top flange of the coil, with an excitation of 3,500 ampere turns, while the double taper core point was 1·4in. above and outside the top flange of coil; thus the effect of tapering the bottom and top ends of the core, as compared with the top end only, raises the core 1·9in. in coil for same minimum excitation. This difference disappears as the cores are weighted, but the double taper core seems to rise much quicker in the beginning than the single taper core, and then bends over rather quickly at the end of its range.

For greater convenience in comparing the different cores, the results are arranged in sets, first taking the four different cores under the following conditions, viz.:—Core only, core plus 35oz. attached, core plus 52oz. These results plotted give the curves Figs. 5, 6 and 7 respectively. Secondly, on each sheet of curves a section of the top of the coil is given full size, the zero line of travel corresponds with the outside top edge of the coil, and the first point in the curves gives the various positions of the core with minimum excitation (or the least number of ampere turns that will sustain the core). In this set the position of each individual core and the amount of excitation with different weights is given; and, lastly, the effect of using the coil iron clad is given for cores Nos. 3 and 4. The latter core was tried with a weight of 100oz. attached.

It may be here mentioned that the weights used were made of lead, to avoid any disturbance of the lines of force; this also accounts for the odd weights 35oz., 52oz., and 100oz, instead

Digitized by Google

of 25oz., 50oz., and 100oz., say, or the succeeding weights being some multiple of the first weight.

Table II. gives the result of the 12 experiments with these four cores, under the condition of—core only, core plus 35oz., and core plus 52oz. For the sake of comparison, columns 4 and 5 give the travel of each core under the conditions above mentioned for a variation of 5,000 ampere turns excitation.

In the first set, 2 to 2*c*, with core only, the 6in. taper gives a travel of 4in., and movement of the core is more nearly proportional to the increase of excitation than the others. Next in merit comes the 2in. taper core, which has a travel of 2·9in. The square-ended and double taper cores are almost equal as regards the travel; but the former gives best movement. By best movement I mean a motion of the core proportional to the increase of excitation and the whole arrangement sensitive to the changes in the amount of excitation.

The next set, 3 to 3*c*, the core had a weight of 35oz. attached (or total weight about double that in 2 to 2*c*). Here the double taper core gave the largest travel, 3·2in. Next

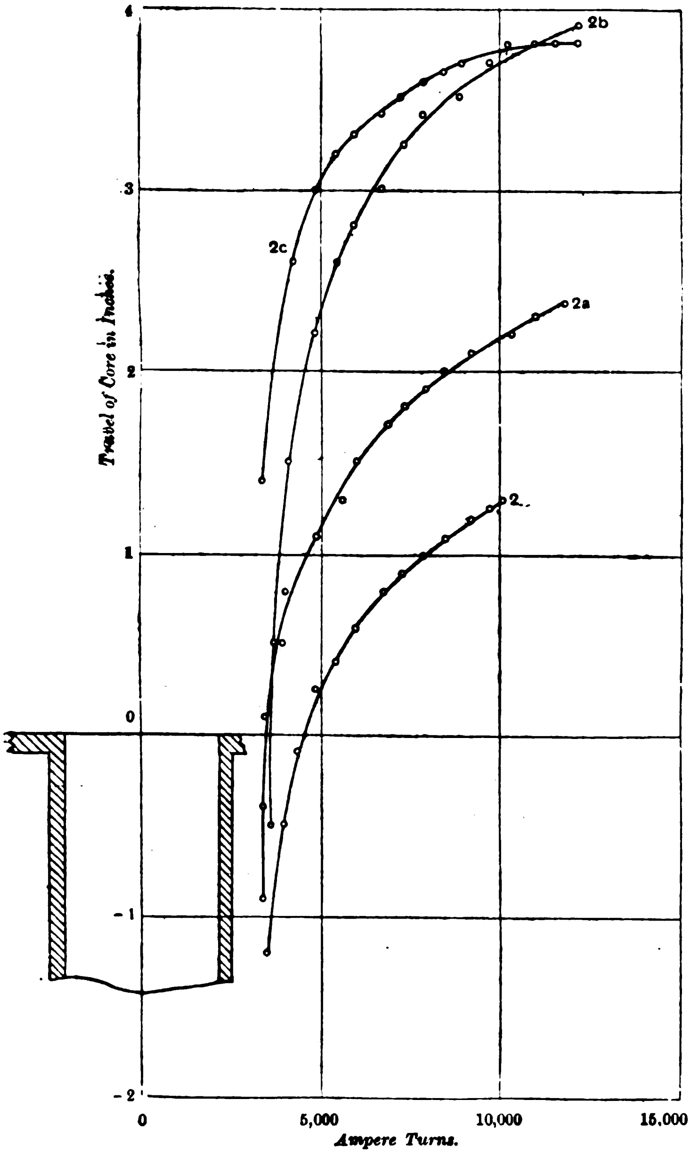


Fig. 5.—Core only.

comes the 6in. taper core (3*c*), with a travel of 2·7in.; the 2in. taper (3*a*) and square ends (3) come next, with travels of 2·15in. and 1·9in. respectively. Although in this set, from the point of view of maximum travel, 3*c*, or double-taper core, is the best, yet upon examining the curves we can find that 3*b*, or 6in. taper, is more suitable for the purpose aimed at, as this curve may be said to be straighter than any of the other of the same set.

Coming to set 4 to 4*c*, the core had a weight of 52oz. attached (or total weight nearly treble that in 2 to 2*c*). Here again

Table II.

—	Max. travel.	Max. S *i* variation	S *i* variation.	Travel for 5,000 S *i* variation.	—	
2	2·6in.	6,600	5,000	2·3in.	Square ends	core only
2*a*	3·25in.	8,100	5,000	2·9in.	Taper 2in. one end	
2*b*	4·4in.	8,800	5,000	4·0in.	Taper 6in. one end	
2*c*	2·4in.	8,800	5,000	2·25in.	Taper 6in. both ends	
3	2·0in.	6,100	5,000	1·9in.	Square ends	core +35 oz.
3*a*	2·25in.	5,750	5,000	2·15in.	Taper 2in. one end	
3*b*	3·0in.	6,100	5,000	2·7in.	Taper 6in. one end	
3*c*	3·3in.	6,100	5,000	3·2in.	Taper 6in. both ends	
4	1·4in.	4,000	5,000	1·5in.	Square ends	core +52 oz.
4*a*	1·9in.	4,700	5,000	1·9in.	Taper 2in. one end	
4*b*	2·8in.	6,500	5,000	2·45in.	Taper 6in. one end	
4*c*	2·7in.	5,400	5,000	2·55in.	Taper 6in. both ends	

the double core has the maximum travel, 2·55in., not very much more than 4*b* or 6in. taper, which has a travel of 2·45in.; 4*a*, or

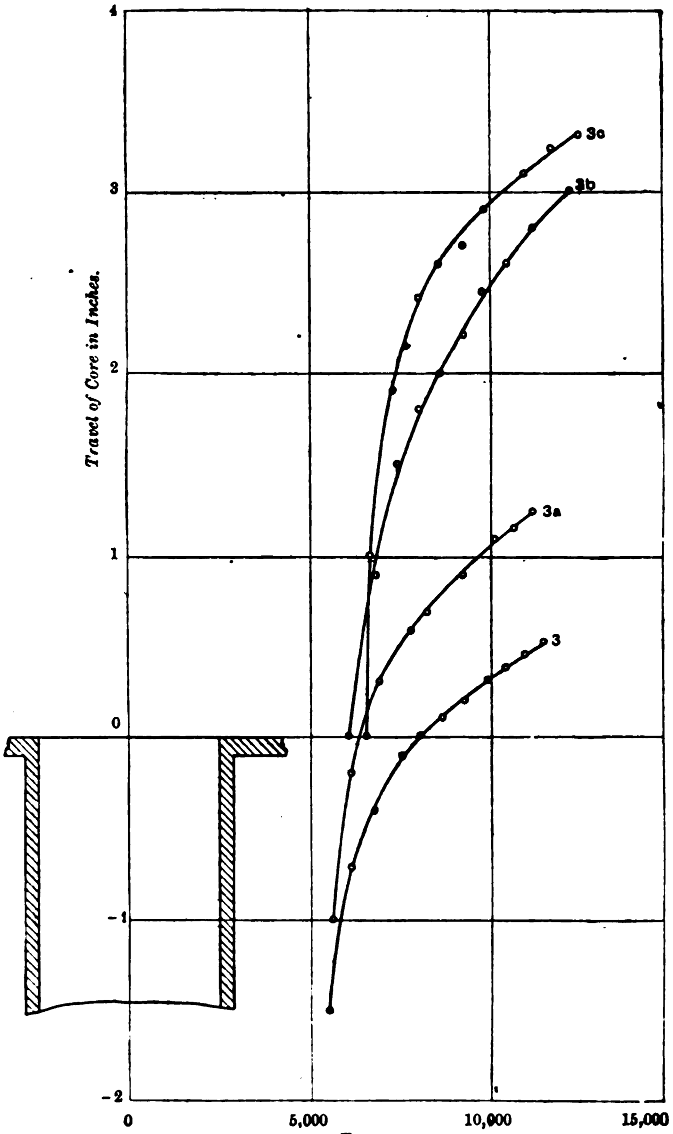

Fig. 6.—Core + 35oz.

the 2in. taper core, has a travel of 1·9, and 4, or cylindrical-ended core, travel 1·5in. In this set, as in the last, the 6in. taper core gives the best result, as an inspection of the curve will show; here the distance travelled is almost proportional to the increase of excitation.

Bearing in mind the object of these experiments, *i.e.*, maximum strength, range, sensitiveness, and equal increments of travel for equal increments of excitation, it seems as if 4*b*, or the 6in. taper core, weighted to 52oz., is the best; next comes 4*c*, or the double taper core.

Digitized by Google

It is interesting to examine the different positions taken up by the point of the core with the least excitation, *i.e.*, the smallest number of ampere turns that will sustain the different cores under different conditions. Take the cylindrical-ended core: with the core only, smallest excitation is 3,500 ampere turns, and the point of the core 1·2in. inside and below the top flange of the coil. With 35oz. attached to the core, least excitation is 5,500 ampere turns, and point of core 1·5in. inside and below top of coil. Increasing the weight to 52oz., the minimum excitation is 7,000 ampere turns, and point of core is 1·2in. inside and below top of coil, or exactly the same position as when the core had no weight attached and the excitation was half the present amount.

Next take the core No. 3, tapered 2in. from the top, with core only; the minimum excitation was 3,500 ampere turns, point of core 0·9in. inside and below the top of coil. When the 35oz. were attached to the core the point was 1in. inside and below the top of the coil, and minimum excitation was

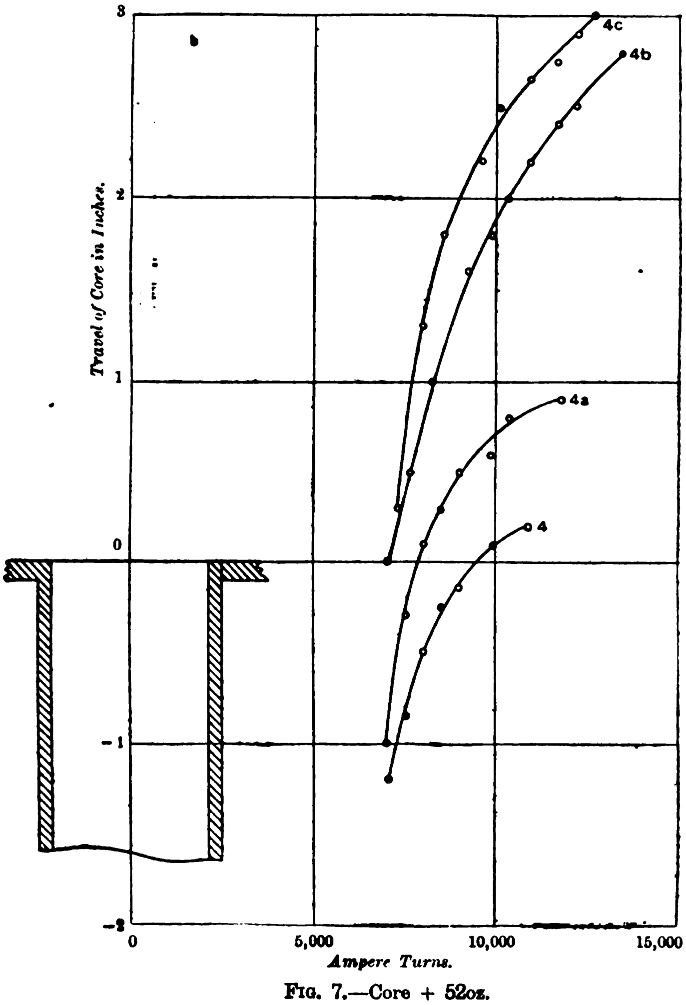

Fig. 7.—Core + 52oz.

5,500 ampere turns. With weight increased to 52oz. the minimum excitation was 7,000 ampere turns, and point of core was 1in. inside and below top of coil, or same position as with 35oz. attached, but 55,000 ampere turns.

Now take No. 4 core, tapered 6in. from point downwards, with core alone; minimum excitation was 3,500 ampere turns, and point of core took up a position 0·5in. inside and below top of coil; attaching 35oz. to the core, the excitation was 6,000 ampere turns, and point of core just flush with top of coil; when the weight was increased to 52oz. the figures were 7,000 ampere turns and point of core just flush with top of coil.

Lastly, using core No. 5, tapered for 6in. top and bottom, with core only, the minimum excitation was 3,500 ampere turns, and point of core was 1·4in. outside and above top of coil; when the 35oz. weight was attached to core, the excitation was 6,500 ampere turns, and point of core was flush with top of coil; the same position as No. 4 with same weight, but requiring 500 ampere turns more; and finally, attaching the 52oz. to core, excitation and position was 7,380 ampere turns, and point of core 0·3in. outside and above top of coil.

Summing up with respect to minimum excitation and position of core, the excitation seems to remain constant for the different kinds of core under the same condition with regard to the weight, and the position of point seems to vary without regularity.

The effect of using the iron jacket was next tried, but cores Nos. 3 and 4 only were used. Referring to the results obtained in the first set of experiments with the coil iron clad, it would seem as if the action was no longer that due to a core and solenoid pure and simple, but depended upon the variation of the air gap to move the core. The square-ended core was not used in this experiment, as once the circuit was closed the point of the core would immediately fly to the top of the coil, and the air gap remaining constant, no movement of the core would take place by varying the excitation.

For an almost similar reason the double-tapered core was discarded. This core, being tapered in opposite directions for 12in. of its length, only leaves 3·5in. of the core parallel. Now, the coil being 7in. long, it can be seen that by the time the top of the core was flush with the outside of the iron jacket the other taper in a reverse direction comes into action at the bottom of the core; thus the result would be a sort of differential action—that is to say, when the air gap at the top of the coil was tending to decrease by reason of the upward movement of the core, the air gap at the bottom would commence to increase, and a large range was not to be expected; in addition, the weight supported would in all probability be small. Returning to the cores actually tried, we see from the curves plotted the vast difference made in the shape of the curve by increasing the length of the taper.

With No. 3 core (2in. taper) the curve rises quickly at first and then bends sharply, giving a very small travel. This happens with 35oz. and 52oz. attached; the travel is slightly reduced by the latter weight. Compare this result with that obtained with No. 4 core under similar conditions. Here we get a curve fairly straight, and a range more than twice as great for the same variation of excitation.

Referring to columns 4 and 5, Table III., which gives the travel of the two cores under the condition mentioned, and taking 5,000 ampere turns variation as a standard for comparison, with No. 3 core loaded with 35oz., the travel is 1·2in., while, increasing the weight to 52oz., the travel is 1·1in., and the curve is even more regular, although both are entirely unsuitable for their purpose (*see* curves, Fig. 8).

Table III.

—	Max. travel.	Max. S*i* variation	Trav'l for 5,000 S*i* variation	—	—	
3a¹	1·7in.	9,250	1·2in.	5,000	Core + 35oz.	2in. taper.
3b¹	1·4in.	9,000	1·1in.	5,000	„ + 52oz.	
4a¹	3·7in.	7,250	3·15in.	5,000	Core + 35oz.	6in. taper.
4b¹	3·6in.	6,500	3·05in.	5,000	„ + 52oz.	
4c¹	2·3in.	3,750	3·1in.	5,000*	„ + 100oz.	

Using core No. 4 (6in. taper), with 35oz. attached, the travel for 5,000 amperes variation is 3·15in.; increasing the weight to 52oz., the travel is 3·05in., or only 0·1in. less. With this core the weight was further increased to 100oz., and the curve is almost a straight line. In this case the excitation was only varied through 8,750 ampere turns, the minimum being 9,200 and maximum 12,500 ampere turns; for the variation the travel is 2·3in., producing the curve through a range corresponding to a variation of 5,000 ampere turns, shown by the dotted part of the curve; the range is 3·1, or practically the same as with 35oz. and 52oz. attached, but the curve is straighter, although the weight is nearly treble that first used. From these results it would seem, by properly proportioning the length of taper and weight supported by the core, that the curve connecting travel and excitation may be made absolutely a straight line.

* Assumed.

Digitized by Google

Undoubtedly No. 4 core with iron-clad coil gives the best result, but it lacks the sensitiveness obtained when the coil is used without the iron jacket. This sluggishness might, I think, be overcome to a great extent by very carefully centring the coil with respect to the iron jacket, and ensuring that the core is a good fit in the coil.

In experimenting with some smaller coils and taper cores I found it a very good arrangement to have the core tube slightly

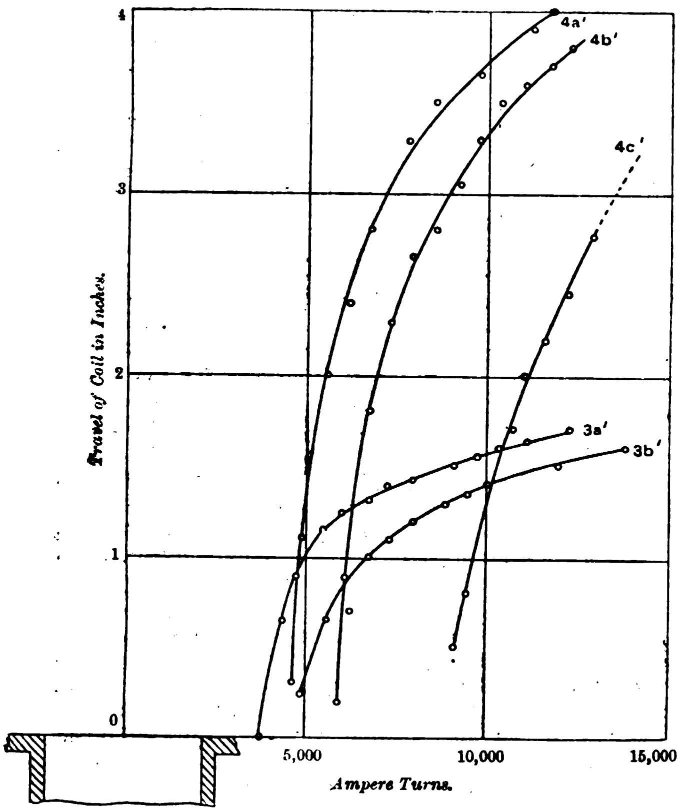

Fig. 8.—Iron-clad.

larger in diameter than the core, say $\frac{1}{16}$th of an inch, and to secure the core in a very thin brass tube, making the latter a good yet easy fit in the former (Fig. 9).

The want of sensitiveness due to the use of the iron jacket appears from the experiments to be due to the air gap between the core and iron jacket not being exactly the same width all round the core. The smallest amount out of line between the coil and jacket axis makes an incredible difference, so much so

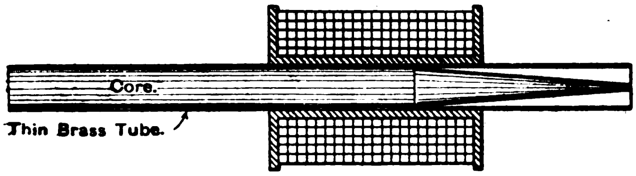

Fig. 9.

that, comparing two curves obtained with same core, one carefully centred with respect to the holes in the iron jacket and the other slightly out of truth, the former give a series of points perfectly regular and sensitive, while the latter gives the points of the curve so much out of line that it requires a stretch of imagination to draw the curve between the points instead of from point to point, and the core keeps sticking, and would take up several different positions for the same number of ampere turns.

At first it seemed as if this sluggishness was due to the better magnetic circuit, but the result of the experiments seems to point to the reason given above. No doubt the better magnetic circuit may have a little effect upon the sensitiveness, but want of proper adjustment seems to be the principal cause.

Before leaving this part of our subject, it may be instructive to compare the effect of the iron jacket upon the position taken up by the point of the core with minimum excitation; with that obtained with the same core and weight without this jacket. Taking No. 3 core first, we find that, weighted with 35oz., minimum excitation was 5,500 ampere turns and point of core 1in. inside coil; with iron jacket minimum ampere turn was 3,700, and point of core was flush with top of coil. Increasing weight to 52oz., minimum ampere turns were 7,000, and point of core was 1in. inside coil; using iron jacket the ampere turns and position of core were respectively 5,000, and point of core 0·2in. outside of coil, or 0·2in. inside iron jacket. Turning to No. 4 core, weighted with 35oz., the minimum excitation was 6,000 ampere turns and point of core flush with top of coil; using the iron jacket the above numbers became 4,600 ampere turns and point of core 0·3in. outside top of coil and 0·3in. inside iron jacket. When the 52oz. weight was attached the minimum ampere turns were 7,000 and point of core was flush with top of coil; the effect of the iron jacket was to make minimum excitation 6,000 ampere turns and point of core 0·2in. inside iron. Thus in all cases the iron-clad coil supported the core and weight with less ampere turns, and drew the core further in than when the coil was used alone.

(To be continued.)

THE TELEPHONE SYSTEMS OF THE CONTINENT.

BY G. L. ADDENBROOKE.

Mr. A. R. Bennett during last year spent some months in making a tour of the Continent with the object of inquiring into and noting the position and progress of the telephone in each country. The results of his experiences are now embodied in a book with the above title which has lately been published by Messrs. Macmillan and Co.

The first effect of this work is rather confusing, because it commences by a long introduction of 30 pages, in which the matter which follows is employed in an attempt to demonstrate how badly the public have been served by the holders of the existing telephone monopoly, and to show how much rates might be reduced and the utility of the telephone extended if municipalities, companies, or co-operative societies were allowed a free hand to erect and work exchanges for their mutual benefit. Thus the reader is plunged at once into the middle of a controversy and confronted by statements for which as yet he has received no warranty.

The idea is thus conveyed that the book is technical and out of the province of general readers and telephone users, who, on the other hand, are the people for whose benefit the book is presumably written.

If, however, readers will skip the introduction, and read first the data and descriptions which Mr. Bennett gives, the mind will be carried comfortably along, and the result is that one is led on to comprehend of the subject after a fair amount of easy reading, diversified by a good sprinkling of valuable illustrations and with an occasional semi-humorous touch, such as the description of the method of settling disputes between subscribers and operators in Paris. Having thus gone through the book it is easy to turn back and read the *introduction* effectively and follow Mr. Bennett's arguments. Logically, this introduction should have been the *conclusion*, and come at the end of the book with a separate title-page.

The descriptions of the results attained abroad would then have gained in prominence, the appearance of bias would have been removed, and the authority of the book and its influence on the public and on the Committee of the House of Commons which has recently been dealing with the question would have been enhanced. So much for general criticism.

Seeing that, apart from the manner of the book, the matter raised grave issues, the writer thought it would be worth while calling on the National Telephone Company and at the Post Office to find out in what light they viewed Mr. Bennett's efforts. At the Telephone Company's office, after sending in his name and object, the general manager returned a message to the effect that he had read the book, and did not think it of much account, but that the Company would be pleased to show him

Digitized by Google

(the writer) their exchanges, and explain what they were now doing. At the Post Office the authorities are not pleased with Mr. Bennett's references to them, which we think he would have been wiser to omit, as there is another version which quite simply explains the apparent discourtesy noticed in Mr. Bennett's introduction. This is not, however, the place to discuss the attitude and position of the Post Office authorities towards the telephone; but of the policy and actions of their technical advisers it is impossible to speak without high praise. The writer has a pretty adequate knowledge of the comparative attention which has been bestowed on the scientific study of the telephone both in the Post Office and the National Company, and while the investigations which have been made by the Post Office, and which have just resulted in the splendid trunk lines to Glasgow and Dublin, must command the admiration of any impartial observer, on the other hand the short-sighted repression of all scientific work, which was the keynote of the late United Telephone Company's policy, and the luke-warm support of it by their successors, is very unfortunate when one thinks of what might be done for the public good and convenience if a really enlightened policy were adopted, instead of an unwilling and ungracious acquiescence in improvements which have been forced by public opinion from outside instead of arising from increasing knowledge and experience within. The administration of the Company has certainly improved recently, but had they from the first adopted a more enlightened attitude technically towards the nation they would have been saved many of their difficulties, and would have secured better treatment from the Post Office, which is really the guardian and mouthpiece of the national will in this question.

Mr. Bennett's statistics and arguments must be left to speak for themselves, and we hope later on that the author will see his way to condense them and eliminate the less important, so that the gist of the work could be presented to the general reader and telephone user in a small volume at a price which a non-technical reader would be likely to pay. As it stands, while the work is valuable to practical telephonists, the majority of telephone users can hardly be expected to buy it.

THE BRUSSELS ELECTRIC TRAMWAY.

There are two lines of electric tramway at Brussels. The one runs from the Midi to the Nord railway stations, following a semi-circular route through the main boulevards of the town, and is three miles long; the other runs from a point in the south-east of the town to a suburb, Uccle, and is 2·7 miles long. The generating station is about a quarter of a mile distant from the Midi end of the Midi-Nord line. The Uccle line branches from the other at about two miles from the Midi station.

The whole plant and equipment was ordered by the Brussels Municipality from the Union Elektricitäts Gesellschaft, of Berlin. It was completed in June, 1894, the Union Company undertaking to work it for the Municipality for two years at a guaranteed maximum expenditure per kilowatt-hour. As, however, the expense of working has been considerably under that guaranteed, the municipality are satisfied, and will take over the line this month.

The tramway is an excellent example of international practice. It is in a thickly-populated district, which has waived its objection to overhead wires, and where coal is cheap and the horses are overworked. The boilers are English, the engines German, the motors American, the contractors' chief engineer (M. Pedriali, who kindly showed our correspondent round the generating station) Italian, and, doubtless, some of the polite gentlemen in the general office are French.

In the boiler house are three Babcock-Wilcox boilers. The boiler pressure is 118lb. per sq. in. The feed water is pumped from the town main by Worthington pumps through a Dervaux purifier, a Schmidt meter, and the feed-heater, where it is heated by the exhaust steam (the engines being non-condensing). A small quantity of lime and carbonate of soda is used to soften the feed water. Native coal, of a poor quality, is used, and the stoking is done by hand.

The engine house adjoins the boiler house, and the steam main is duplicated. There are five tandem engines, built by Ludwig Loewe and Co., of Berlin, each giving 180 I.H.P. The valve gear is Mackintosh-Seymour, and the governor works direct on the throttle-valve. The five dynamos, each 100 kilowatt, are belt-driven. They are of the Thomson-Houston type, but manufactured by the Union Elektricitäts Gesellschaft; they are four-pole and slightly over-compounded. The engines run at 235 and the dynamos at 625 revolutions per minute. The mean electrical pressure at the station is 520 volts. The average maximum current leaving the station during the day is 500 amperes. The daily output from the station is from 2,000 to 2,200 kilowatt-hours. The brushes of the dynamos, as well as of the motors, are of carbon. As an average, 6·6lb. of coal are consumed per kilowatt-hour supplied at the dynamo terminals.

The switchboard is of slate, there being one panel for each machine. The connections are all made behind the board, the back of which forms, as it were, the wall of a narrow corridor with a door at each end, so that the connections can be got at without any difficulty. The switching arrangements are very simple. There are no fuses on the switchboard, but there is a 250-ampere fuse on each terminal of the dynamos themselves.

The cars and line are on the usual Thomson-Houston single-trolley system. The greater part of the line is two-track, both tracks being on the same side of the road. The trolley-wires are in most places suspended from ornamental steel poles placed at the edge of the pavement, and this arrangement is by no means unsightly. Span wires are only used in a few places where there is no room for poles. On part of the suburban line wooden poles are used. The trolley wire is of Felten and Guilleaume's phosphor-bronze, and is 0·322in. diameter. The wire is divided into sections of 550 yards length, insulated from one another. One distribution cable is used, there being no feeders. The cable is from Siemens and Halske, and is insulated with jute and compound, lead-covered and steel-armoured. Both the T and straight-through joints are made in Siemens' cast-iron junction boxes of the well-known pattern. The rails form the return circuit, without a supplementary cable or feeders. The "channel-pin" bond is used to connect them.

There are 22 cars running during the day, each consisting of a motor car and trailer, each car being designed for 35 persons. The cars, when empty, weigh 6½ and 2½ tons respectively. The steepest grade is 6·8 per cent. The motor cars are each fitted with two Thomson-Houston single-reduction 15 H.P. motors of the W.P. 30 pattern. The motors are series-wound, and can be switched by the driver either in series through a resistance, in parallel with a rheostat in series, or each singly on to the line in series with the rheostat. The maximum speed of the cars in the town is about 12 miles an hour; outside the town, 15 miles an hour.

THE MEXICAN GOVERNMENT TELEGRAPH SERVICE.

Within the past ten years the telegraph service in Mexico has undergone a complete transformation under the able and energetic management of Saturnino Islas, who was singled out for the task by President Diaz when carrying out those great reforms in the civil service which are associated with his name. Previous to 1885 the telegraphs in Mexico were almost a bye-word on the American continent. The operators were political nominees, who seem to have drawn their salaries, like their patrons, for party services, and not for the work they were supposed to perform. The lines were in a deplorable condition, and had obtained such an evil reputation that travelling by night was rendered dangerous through the prevalence of broken or derelict wires on the roadways. Contractors who had charge of the maintenance neglected their obligations, though drawing their payments punctually. If the accounts recently published by the *Electrical Engineer* of New York are correct, half the messages entrusted to the Mexican authorities never reached their destination; and, as a natural result, the service was comparatively little used, whilst

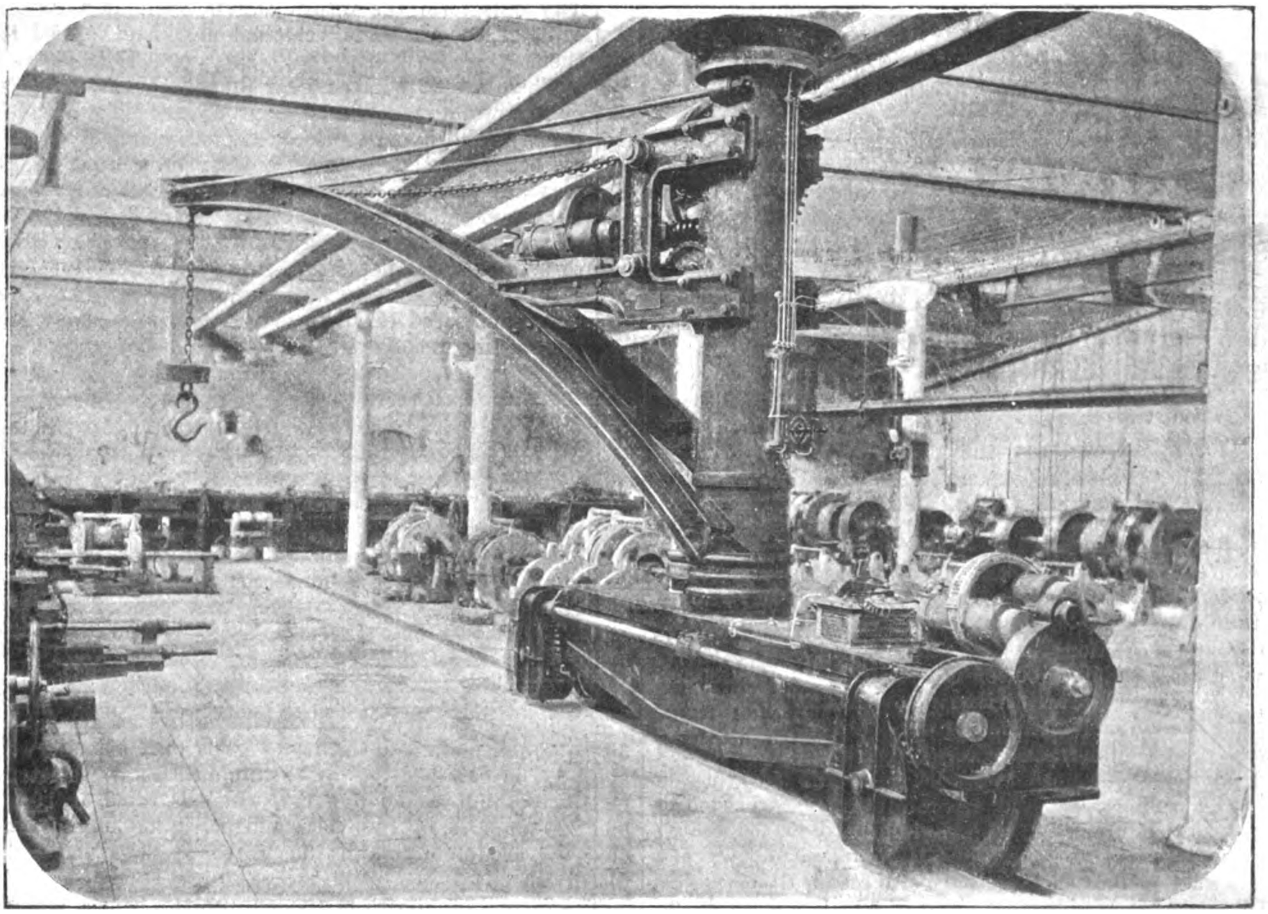
Digitized by Google

the expenditure was far in excess of the revenue. Saturnino Islas has now changed all this, and the financial position of the Mexican telegraph system now compares favourably with that of any other department of the Mexican Republic, which has made such rapid strides of late that its revenue is more than double what it was some 20 years ago. Having studied modern telegraphy in the United States, and applied his knowledge practically on the Vera Cruz Railway, Saturnino Islas went to work in reorganising the department over which he speedily acquired sole control. By first changing the *personnel* of the service and then setting to work on the repairs of the lines, he soon made it evident that traffic would not be slow to follow restored confidence. Competent operators took the place of the old ornamental employés; the lines were got into working order, and useful extensions carried out on an efficient and rational scale, so that at this moment there are 26,000 miles of wire and 806 stations directly under Government control. The central office in the capital is handsomely appointed and thoroughly well manned; whilst the country is carefully divided under the direction of able superintendents, who are held responsible for the maintenance of their several sections.

It should be noted that the Government telegraphs in Mexico are primarily for State purposes—that is to say, for the service of the army, a very important function in countries like the South American States, where the population is always turbulent, and more or less given to revolutions. Consequently we do not look for an ideal tariff in those regions suited for popular use such as we consider essential on the European continent. But we should have expected from Saturnino Islas, who in other respects has shown many qualities of independence and originality, something better than the "zone" system of charges—a system which is neither sound in theory nor good in practice. The tariff, as designed by him, ranges from 20 cents to 2 dollars for a message of 10 words, the rates varying by 20 cents for every 120 miles (180 kilometres) or fraction of the same—that is to say, every office is treated each as the centre of a number of circles that distance apart, the charges therefore varying according to the zone in which the place is situated to which the telegram is going. Approximately this is charging by distance, but the approximation is so wide that the difference of cost must appear very arbitrary in the case of places situated near the zone boundaries but on different sides of them. It is claimed for this system that the official can see at a glance what the charge must be when he has found the place on the plotted map; but it leaves out of account the customers' ignorance as to a detail of that sort. Nobody knows what he may have to pay beforehand; and this circumstance deprives the system of all title to being a popular one. Experience has proved that a charge based strictly upon distance is not theoretically defensible, seeing that the expense, after first cost, does not vary by distance. But a tariff framed on approximate distances is altogether indefensible. Mexico is settling down into habits of peace and civilisation; it is perhaps not too much to hope from it that a tariff more in accordance with the experience of older countries abroad may soon find favour in that country. It is interesting to note that all the cables used in Mexico are manufactured in England.

A WORKSHOP ELECTRIC CRANE.

The accompanying illustration has been reproduced from a photograph sent us by M. Fabius Henrion, of Nancy. It



represents a 6-ton electric crane. As the rail upon which the crane runs extends the whole length of the shop (80 metres), and as the jib has a radius of action of 5 metres, the crane is able to serve an area of 80 by 10 metres. The crane picks up the castings as they arrive, takes them to the various tools, thence to the erecting shop, thence

Digitized by Google

to the testing shop, and afterwards to the spot where the machines are painted, packed, and put on the trucks. At the bottom the crane runs on a single Brunel rail; at the top it is guided by two iron girders between which runs a roller. Along these two girders run two wires, from which the current is collected by two brushes. The movement of translation is effected by the motor mounted on the carriage, the motor being caused to drive the crane ahead or astern, slowly or quickly, by means of a lever turned more or less to the right or left. The reversal of the motor is effected by reversing the current in the field. Carbon brushes in fixed positions are used. The motor which is seen on the platform between the pillar and jib effects the lifting motions, and is governed by the regulator fixed to the pillar. When the load is being lowered it cannot descend too quickly, for if the speed increases beyond a certain point the motor becomes a generator and a brake is thus automatically put on.

AN EXAMPLE OF INTERIOR CONDUIT WIRING.

BY ALBION T. SNELL.

Some interest now attaches to the use of interior conduits for electric wiring, and perhaps a brief description of a lighting plant which I have recently designed for Messrs. Heelas, Sons and Co., of Reading, may on this account prove of interest.

Messrs. Heelas have one of the largest drapery and furniture houses in the South of England, and their premises extend over a ground plan of more than an acre. The buildings vary from two to five stories at the front and back of the block,

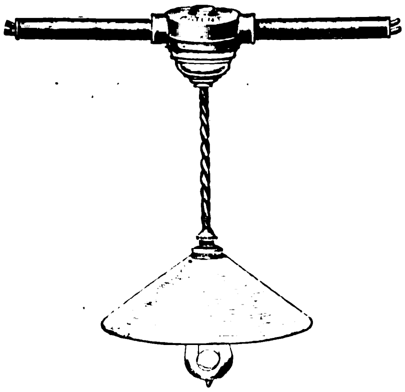


Fig. 1.

while in the centre portion they are generally of one storey with a lofty skylight. Consequently the levels of the ceilings differ in all the departments. Owing to the peculiar arrangement and construction of the interior of the buildings it was felt that wood casing was unsuitable. It was not strong enough to be carried in air from point to point as was absolutely necessary, and, moreover, it would be unsightly in many places, even assuming it could be economically and securely erected. Accordingly it was decided to use iron pipes throughout, running the conductors in pairs in one pipe.

To facilitate the distribution and balance the fall of pressure the area is divided up into sections, and each is served by a feeder from the engine house. In some cases sub-feeders are carried from the section boxes to smaller distributing boxes, but in most cases the distribution is effected from the section boxes. The sub-circuits are divided into circuits of five amperes each. The section and distributing boxes are all made of cast iron, with glazed iron-framed doors. The iron pipes to and from the boxes are tapped into sockets in the sides of the boxes. The ceiling roses and separate switches are fixed in iron bases, so that from the main switchboard to the ceiling roses the conductors are encased in iron pipes, and are free from the least chance of an electric fire, and they are also practically safe from mechanical injury. The lamps are chiefly suspended by strong flexible cord (Fig. 1), but a few are fitted as shown in Fig. 2.

The generating plant is situated in a separate brick building with the accumulator house alongside. The plant comprises a Crossley Otto 14 nom. H.P. gas engine of the new scavengering type, which indicated 43 H.P. on testing when first erected (*see* Figs. 3 and 4. It has the usual heavy flywheels and electric-light governor, and ordinarily runs at from 204 to 200 revolutions per minute. Since the initial pressure of the exploding gas, with this type of engine, is about 250lb. to the square inch, and the exhaust is made at from 40lb. to 30lb., some difficulty

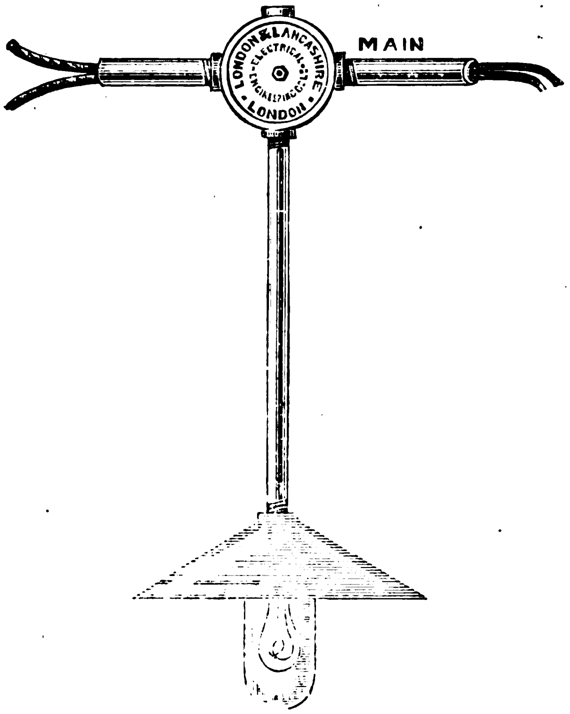

Fig. 2.

was experienced at first with the noise. Ultimately it was overcome, and the engine now makes little, if any more, noise than one of the same power of the ordinary type. There is a 4-in. cast iron exhaust pipe about 58ft. long leading into the top of a "hangdown" silencer with an open bottom, fixed into a brick chamber laid in cement and built into the ground.

Fig. 3.—Indicator Diagram of 14 N.H.P. Crossley Gas Engine of "Scavenger" type. Full Load. 200 revs. and 100 explosions per minute. 43 I.H.P.

The uptake for carrying off the fumes has an area of about 36 square inches, and the discharge is made almost without noise. The engine drives by belting an Electric Construction Company shunt-wound dynamo, which is rated at 105 volts and 220 amperes, or 140 volts and corresponding current for charging accumulators. It has three bearings and a heavy disc flywheel.

The main switchboard is divided into two panels, one for the positive connections and one for the negative, in the usual manner. The feeders are all brought to omnibus bars, and have

Digitized by Google

a switch and fuse to each main. Ammeters are provided for reading both the current from the dynamo and that given to or from the cells, and a voltmeter with two-way switch enables the dynamo and feeder pressures to be read as desired. There is also a magnetic cut-out in the charging circuit which cuts in the cells when the dynamo pressure is high enough for charging, and cuts them out in the event of the pressure falling. The storage battery consists of 55 R5 Epstein cells, which have a capacity of about 200 ampere-hours at 50 amperes discharge. They act as a regulator during the hours of lighting, and as a storage reservoir for the light load by day and the night load after the shops are closed.

There are six arc lamps each of 2,000 c.p. nominal, and the equivalent of 850 incandescent lamps of 8 c.p. each, the actual number of lamps being about 528. Great care has been taken in the arrangement of the lamps to secure the best illuminating effect, and economy of power has been specially studied on account of the short hours of full-load working. All the incandescent lamps are of 3-watt efficiency.

The chief point of interest to users of gas-engine plant is the consumption of gas in the engine per B.T.U. This has been ascertained with considerable accuracy, as the gas is supplied through a separate meter. Reading gas costs 2s. 9d. per 1,000 cubic feet. From the mean of tests taken at different times and by different observers it appears that the cost of gas, at a maximum output of six arc lamps and about 450 incandescent lamps of various powers, is a little less than 1·25d. per B.T.U., and at a minimum output is 1·75d. These figures have never been beaten, I believe, for a plant of the same size.

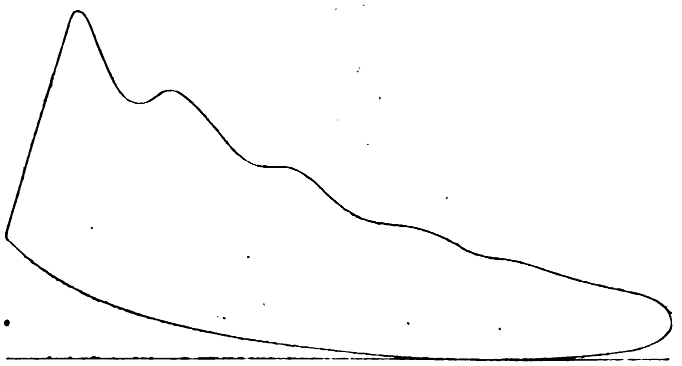

Fig. 4.—Indicator Diagram of 14 N.H.P. Crossley Gas Engine of "Scavenger" type Running Light. 200 revs. and 21 explosions per minute.

The cells are charged, when necessary, in the mornings from 9 o'clock until about midday, it being found that this is sufficient in a general way. During charging, a few lamps are run in the basements through a suitable switch arrangement. The cells supply the lamp current until it reaches 50 amperes, when the engine is started and kept running until the demand falls again to 50 amperes. In the winter time the engine runs for the lighting service from about 4 o'clock until half-past 7 or 8. The house has about 70 incandescent lamps installed in the service rooms, sitting rooms, dining rooms, and bed rooms, the current for which is supplied from the battery when the engine is shut down.

Mr. Musgrave Heaphy made an inspection of the plant, and expressed himself as being highly pleased with the use of iron piping and iron distributing boards, and the general method upon which the wiring was planned. The whole of the work was carried out by the London and Lancashire Electric and General Engineering Company to the plans and specifications of the writer.

Magnetic Observatory for Greenwich.—Provision has been made in the Navy estimates for the erection in Greenwich Park of a magnetic pavilion for absolute determinations of the magnetic elements, and the plans are now being prepared in the Director of Works' department. It is proposed to establish this station in the immediate neighbourhood of the Observatory, and at such a distance that there would be no suspicion of disturbance from the iron in the buildings.

THE BRUSSELS CENTRAL ELECTRIC LIGHT STATION.

By the courtesy of Mr. Pullar-Phibbs, electrical engineer to the Brussels municipality, an occasional correspondent of this journal was recently able to view the Brussels central lighting station. Our correspondent's impressions are given below. He gives several items of information not to be found in the description of the station which appeared in our issue of March 30, 1894.

The chief part of the load at Brussels is spread over a rectangle whose sides are about 1 mile and $\frac{2}{3}$ mile long. The station is at the Place St. Catherine, at one of the corners of this rectangle. At present there are 30,000 lamps of 8 c.p. (or the equivalent) connected to the mains. The three-wire system with accumulators is used, the pressure between the outer mains being 220 volts and the middle wire not being earthed. The distribution network is fed at 11 points, and it is intended shortly to increase this number to 24. At every feeding-point there are feeders to all three mains.

The boilers are by Babcock and Wilcox, and are similar to those at the tramway generating station. They are fitted with "smoke preventers" on the Orvis system, but these are not used, as coke is burnt. This system consists of leading a mixture of steam and air to the top of the fire, each furnace being provided with four of these inlets. The feed water, which is obtained from the Willbroeck canal, is softened with lime and carbonate of soda, and a purifier by Dervaux of Lille is used, as at the tramway station.

There are eventually to be six engines, each of 650 H.P., though only three have been put down at present, one alone being now sufficient to take the maximum load with the help of the battery. They are horizontal compound engines, built by Carels Frères, of Ghent, and are fitted with Sulzer valve gear and jet condensers, which latter produce a vacuum of 25·6in. Each engine rope drives two dynamos through rope driving. The engines run at 60, the dynamos at 300 revolutions per minute. The latter are separately-excited four-pole machines with drum armatures, built by La Société Anonyme Electricité et Hydraulique (formerly Julien Dulait) of Charleroi. Each machine is designed to give a maximum current of 1,200 amperes at 130 volts. The field magnets are excited by the batteries, and are connected two in parallel, two in series. Thus connected their resistance is $5\frac{3}{4}$ ohms, and they require a current from 10 amperes at light loads to 18 or 19 amperes at full load.

The battery consists of 140 Julien cells. The boxes are of lead; they contain 41 plates $101\frac{1}{2} \times 101\frac{1}{2}$in., and their capacity is 3,500 ampere-hours. The normal maximum rate of discharge is 350 amperes, but they are guaranteed to give 1,400 amperes for half an hour without damage to the plates.

The switchboard is on a gallery, as at some of the London stations, and does not present any novel features. All the feeders are brought to the switchboard, and each is connected to the omnibus bar through a rheostat, there being a voltmeter for each feeding point. The accumulator regulating switch is of the usual vertical type, there being 25 regulating cells. There is an automatic switch between the dynamo omnibus bar and the battery, which breaks contact when the current falls to a certain value. To give a rough indication of the condition of the insulation of the mains, a high-resistance voltmeter is inserted in turn between each outer main and earth once a day. If the two readings differ a little, but not too much, the mains are considered to be in a good condition; if the two readings are exactly equal the middle wire falls under suspicion. There are also recording ammeters to record the current leaving the accumulator terminals. The instruments are all of Hartmann and Braun's manufacture. The board is of black marble, and all the connections are at the back, where they are only with difficulty accessible.

The testing room, which is honoured with the title of "Chambre de Vérification," is on the first floor. There is a complete cable-testing set of the same design as that in the India-rubber Company's testing rooms at Silvertown. It includes a four-coil Kelvin mirror galvanometer, a four-dial Wheatstone's bridge, Rymer-Jones keys, &c., all of the Silver-

Digitized by Google

town manufacture. The galvanometer is suspended on four india-rubber tubes, but there is no arrangement for supporting the instrument when dusting it. There is, in addition, a Crompton's potentiometer, with an Ayrton-Mather l'Arsonval galvanometer, for checking and calibrating the station instruments. There is also a spare Carpentier-d'Arsonval galvanometer.

The mains have all been supplied by the India-rubber, Gutta-percha and Telegraph Company. They are of vulcanised india-rubber, and are drawn into cast-iron pipes, there being a separate pipe for each of the three mains. The testing wires for all three mains are in the same pipe as the neutral wire. The section of the neutral cable is, on an average, about half that of the other cables. All the drawing-in, junction and distribution boxes are built of brick. Only a few of them are drained, and there is no system of ventilation. The ends of the pipes in the boxes are not blocked. The house service cables are T'd from the distributing mains by solid joints, which are insulated with india-rubber, and mostly not vulcanised. The insulation of the complete network is 350 to 400 ohms; this is high, considering that the minimum insulation of the house installations is fixed at 2 megohms per lamp.

The Silvertown Company were the contractors for the whole of the plant under the stipulation that as much as possible of it should be of Belgian manufacture. The contractors' guarantee expires next November. The price charged per unit is 80 centimes (7·6d.). Two supplementary stations are being built—one at the Hotel des Chemins-de-Fer, which is also at the edge of the district of greatest load. This station is to be driven by five gas engines of 120 H.P., the gas being obtained from the town mains. The other supplementary station is being built in the Avenue Louise, and will be chiefly for the lighting of the Ministerial Offices, where 4,000 8 c.p. lamps are being installed. This station will not be connected to the network. It will also have gas engines as prime motors, four 60 H.P. engines having been ordered for it.

THE METROPOLITAN WEST SIDE ELEVATED RAILROAD OF CHICAGO.

This line, of which our New York correspondence gave a short description in *The Electrician* of May 10th, resembles in many ways the Liverpool Overhead Railway, and a few of the more important details, as given by the *Street Railway Review*, may be of interest.

The road, says our contemporary, was built for a steam road, and all the plans were drawn for locomotive traction. The credit for inducing the owners of the road to adopt electricity is probably due more to the present general superintendent, W. E. Baker, than to any other man. As general manager of the Intramural Railway at the World's Fair he secured possession of facts and figures which were convincing as to the economy of electricity as a motive power. The structure is the heaviest elevated road structure yet built in America. It was designed to carry safely in service 30-ton locomotives, followed by double-deck cars. The minimum height of the structure above the street is 14ft., the usual height being 15ft. The track is 4ft. 9in. above the bottom of the supporting girders. The supporting pillars are 14½ft. to 18½ft. high. The standard foundation is 7ft. deep and 8ft. square. The girders are 4ft. deep. Distance between pillars is 39ft. to 50ft. The lateral bracing is equivalent to 450lb. per lineal foot of track. The rail is 90lb. T, with four-bolt fish-plates.

The most notable of the structures is the rolling lift or jack knife bridge across the Chicago River. The bridge spans 174ft. from pier to pier. It is really two distinct bridges, each bridge having two tracks. The two parts are raised and lowered separately. The west halves are operated from an elevated tower between the tracks, and the east halves from the switch and signal tower south of the tracks. The motors, controllers, and air brakes for raising and lowering the bridges are practically identical with the motor car equipments.

The greater part of the structure had been built and many of the rails had been laid before the use of electricity was fully decided on. The laying of the third conductor rail was not, however, attended with much difficulty, except at the complicated switches on some parts of the four-track structure. The trolley contact rail is 45-lb. T, and is run at one side of each track about 7in. above the track rails. It is supported on blocks of wood boiled in paraffin. These blocks are 6in. square, and are mounted on iron brackets about 1in. high. The contact rail is fastened down to these insulating blocks with wood screws and clips. Contact shoes are put on each of the four corners of a motor car, and at switches the third rail on one side is discontinued as on the Liverpool line, and a rail is placed where the shoes on the other side of the car will make contact until the switch is passed. Where the third rail ends at switches, V-shaped frogs, lower at the head than at the point, are provided, so that the trolley shoe will not catch in passing on to a rail. To hold the ends of the trolley rail in alignment, light two-bolt fish-plates are used. The bonds are put under the rail base, and consist of heavy flexible copper strips about $\frac{3}{16}$in. thick, and as wide as the base of the rail. These strips have two rivets in each end, which are riveted up through the base of the rail, one each side of the web. Forty-five pound T rail is also used for feeders. These feed rails are run between tracks, and are boxed over for protection and so as not to interfere with workmen walking along the structure. At switching points and at some stations where there is not room on the structure for the feed rails, copper wire hung under the structure is substituted.

The contact rail is sectioned, each section being controlled by a feeder panel, with circuit breaker at the power house. From the power house, which is only 1¼ miles from the down-town terminus, 18 feed rails go west. The contact rails are sufficient to feed the down-town end. Contact rails are cross bonded, and connected to feed rails about every 300ft., though at switching points and curves this distance is lessened. For a return circuit the track rails are used; these are not bonded at the joints, but are connected at the middle of each rail to the structure. At all connections where copper wire is connected to iron rails, a cast brass rivet is sweated to the end of the wire and riveted to the rail.

At the Chicago River, where the continuity of circuits is broken by the rolling lift bridge, four Simplex rubber and lead-covered armoured submarine cables were laid on the river bottom. A shallow trench was dredged in the mud of the river bottom before they were laid.

The four-track structure necessitates the use of a much more elaborate system of switches and signals than have yet been put on any elevated road. There are three notable pieces of special work. At Marshfield-avenue, where three double-track lines converge to the four-track main line, elaborate special work is put in, which allows the sending of trains in any direction. On the viaduct just east of the Canal-street station is another complicated piece of special work to facilitate terminal switching. At the east side of the river is still another system of interlocking switches for use at the Franklin-street terminus. The system of interlocking switches is similar to that used on steam roads, but has the added complication of the third contact rail, which in some places has to be shifted along with the switches. This problem has never before been faced either by builders of special work or interlocking switches. The tower at Marshfield-avenue has 13 levers for 24 switches, and four movable point frogs; 11 levers for 28 facing point locks, 23 levers for 23 signals, and six levers for working 10 contact rails. There are seven spare spaces for levers, there being a provision for 60 levers on the frame.

The road has at present an equipment of 55 motor cars and 100 trailers. For the first few years trains of one motor and two trailers will be run. The present motor cars have two motors. When the traffic increases enough to justify longer trains, two more motors will be put on each motor car and six car trains can be run. The new cars are 47ft. 2⅞in. over all, and 40ft. over the sills. The width at the sills is 8ft. 7in., and at the eaves 8ft. 11in. The roof is 12ft. 10in. from the rail. These motor cars are intended as smokers, and have none but side seats. The motorman's cab occupies two corners, half of each cab being in the car and the other half occupying half of the platform. To give the car strength to act as an electric locomotive a very substantial steel sub-frame was put on, and in order to have sufficient traction, no attempt was made to lighten anything about the motor cars. The weight of the car, exclusive of the motor, is about 18 tons. They are finished in quartered oak, and have rattan covered side seats. The motor car trucks consist of very heavy steel frames, with central cross beams hung on elliptic springs. One end of each of the motors is suspended from the centre beam. The dimensions of the trail cars correspond approximately with those of the motor cars, and their seating capacity is 48.

This is the first elevated road to adopt an automatic coupler, the Van Dorn coupler being selected. For brake equipment the straight air brake was adopted, as it was thought that the driver has a much more accurate control of his train in making stops with a straight air brake than with an "automatic" brake in which he has not direct control of the valve supplying the brake cylinders. This brake has the disadvantage, of course, that if the train pipe parts the brakes are useless, but in such an event the motors can be reversed and put in parallel with the circuit breaker open. For six-car trains it is hardly practicable to carry an air-storage cylinder large enough to brake a train making frequent stops, although with

Digitized by Google

the present three-car trains the motor car storage is ample. To provide for the future, storage tanks have been put on all the trail cars and are to be connected to the motor car by a separate hose. This arrangement is simply for air storage and is entirely independent of the train pipe supplying air to the brake cylinders.

The electrical arrangements in the driver's cab are very complete. In the right-hand front corner is the air-brake valve. Just left of this is the series-parallel controller. On the wall of the cab, at the left of the motorman, is a circuit breaker. A fuse is also placed in the cab, but it is very heavy, and it is not intended that it shall melt except in extreme cases. The circuit breaker is intended to take care of all ordinary overloads. In one cab is the air pump operated by an electric motor. This motor is automatically cut in and out of action by the air pressure in the main reservoir. This automatic regulator is put on the left wall of the cab, below the circuit breaker. The cab which does not have the air pump in has a small rheostat controller for the air-pump motor. In front of the driver is an air-pressure gauge with two different coloured pointers. One pointer indicates the pressure in the main reservoir and the other the pressure in the train pipe and brake cylinders. To avoid any annoyance from having circuit breakers on both ends of a car, they are connected in parallel, and the driver throws out the one at the rear when he leaves it to change ends.

The series-parallel controller is an imposing structure compared with those used on street cars, providing as it does for four motors and such a heavy current. The arrangement is such that it can be used as a series-parallel controller or as a plain multiple controller. The reason for this is that sometimes, when starting with a heavy load with the motors in series, one pair of wheels will slip and the counter electromotive force of the slipping motor reduces the current flowing through the others, so that the power of starting is still further reduced. With the motors in multiple the slipping of one does not affect the other. The arrangement of the controller is very peculiar. When the controller is off, the handle is always at the left, and when it is at the left the controller is always off. To make a start with the motors in series the driver turns the handle in a direction contrary to the hands of a watch. When he has gone a half a revolution the motors are in series with all the resistance out. To put the motors in multiple he continues turning a full revolution. During the revolution and a half necessary to make the ordinary start the steps have been as follows: During the first half revolution the motors are in series and the resistance is gradually cut out. During the second half revolution the process is reversed, so that at the end of the first revolution the motors are entirely cut out as they were before starting. When, however, the handle begins on the second revolution, the motors are in multiple with the resistance all in circuit. When a revolution and a half has been covered the motors are in multiple with no resistance in. To shut off current and bring controller back to zero, the motorman continues another half revolution. To start with the motors in multiple the handle is turned a half revolution in the direction of the hands of a watch. Indicators on top of the controller plainly show the driver what he is doing. In ordinary service a man need only turn the handle one way, a revolution and a-half to start and a half revolution more to shut off current. The magnetic blow-out is, of course, used on this controller. In the cab near the brake valve is a small handle for turning on the sand. The sand will be blown by compressed air.

The motors are of the General Electric type, weighing about 13 tons each. The armatures are barrel-wound, and the insulation of the motors is asbestos, so that they are believed to be fireproof. Doors are provided both above and below the commutator, and the brush holders can be put either above or below, so that they can be looked after from the car or from the pit. Another feature peculiar to this motor is that there is a cap to slip over the end of the brush, so that a side contact is not depended upon. The suspension of the motor is by a link from the centre cross beam of the truck. The only spring in the suspension is that afforded by the springs in the truck.

All cars are heated with electric heaters, made by the Central Electric Heating Company, of New York, 12 to each car. They are arranged in series of four. When all are in circuit, the current taken is 14 amperes at 500 volts (7 kilowatts). The driver's cab also has a small heater. Every motor car has electric headlights and "markers," or designation lights. The electric headlight is put over the centre of the hood, and the two markers are put on each side of it. The head-light markers and lights in driver's cab, a series of five at each end of a motor car, are on an independent circuit, which is turned on and off as the motorman changes ends.

The contact shoes, of which there are four to each motor car, are supported on wood beams projecting out from the motor truck frames. There is a chilled cast-iron shoe hanging loosely by links slotted at one end. There are no springs about it. A flexible copper wire connects to the middle of the shoe to make electrical connection. The angles of the links by which it is hung are such that it is perfectly rigid in the direction in which the ordinary strain comes, while it will give way to unusual obstructions.

The power plant is at present of about 6,000 H.P. nominal capacity, but could be increased to 12,000 H.P. The distance to the river is about one mile, and provision has been made for running the station condensing. There are four Reynolds-Corliss vertical cross-compound condensing engines, of which two are direct connected to General Electric 1,500-kilowatt generators, and are guaranteed to work satisfactorily with a load of 3,100 H.P. The two small engines are direct connected to 800-kilowatt generators, and are guaranteed to a load of 1,500 H.P. The engines are fitted with a special Reynolds-Corliss valve gear, which allows cutting off steam at any point from zero to ¾ stroke. The cut-off of both cylinders is controlled by a heavy fly-ball governor. The valve gear is also so arranged that if desired the low-pressure cut-off may be set by hand instead of being controlled by the governor. Each engine is provided with a separate governor, which controls a butterfly valve in the main steam pipe. This governor is set so that if anything should happen to the governor which controls the speed of the engine, causing it to run away, the auxiliary governor would close the butterfly valve and shut off steam entirely from the engine before the speed could increase to a dangerous point. The connecting rods for the two sides of the engine are connected to overhung cranks on the ends of the shaft, and the fly-wheel and armature are keyed on to the shaft between the two main frames of the engine. The engines are very heavy and massive, and are spread out wide in all directions on top of the foundations so as to prevent vibration. The principal dimensions of the two large engines are as follows:—Stroke, 48in.; diameter high-pressure cylinder, 36in.; low-pressure cylinder, 72in.; diameter main shaft, 24in.; length, 22ft.; flywheel, 24ft. 4in. in diameter; weight, 150,000lb.; revolutions per minute, 75. With each of these large engines is a Reynolds independent vertical air pump and condenser, with air pump 36in. in diameter by 16in. stroke, driven by a Corliss steam cylinder 16in. in diameter. The two small engines are of exactly similar proportions as the large. The initial steam pressure is 125lb. Each engine has a Stratton separator. A travelling crane runs the length of the engine room, and is operated by electricity.

The boiler room contains 12 300 H.P. Babcock and Wilcox boilers, in batteries of two each. The most interesting thing about this boiler room is the arrangement for handling and burning coal. Coal is thrown directly into storage bins in front of the boilers by being dumped down through doors in the roof from cars on a siding of the elevated structure which passes directly overhead, or it can be hauled by teams to the alley in front of the boiler room and thrown in through the windows. Shoots take the coal from the bins to the hoppers of the mechanical stokers. The grate of this stoker consists simply of an endless chain running over sprockets at the front and rear. The coal from the hopper feeds on to this chain and motion is supplied the chain by a stoker engine furnishing this power for several batteries of boilers. If the right speed is given to the grate, the fresh coal will take fire before it has travelled many inches of the grate, and will be practically consumed by the time it reaches the back of the grate. The motion of the grate over the sprockets at the back throws the ashes down into the pit. The speed of each grate is regulated independently of the main driving shaft by changing the length of the crank working the rachet which drives the grate. This stoker has the advantage over others that it gives a perfectly even and level grate surface, and the grate does not move relative to the coal. This allows the burning of fine cheap fuel, and ensures an evenly distributed admission of air to the fire. Another advantage of this stoker is the fact that at a moment's notice the whole thing can be pulled out from under the boiler, as it is mounted on wheels and runs on a track.

A steel stack 150ft. high and 12½ft. inside diameter lined with brick furnishes the draft. This can be supplemented by two Sturtevant blowers which can deliver air to the ashpits.

A Notable Chemical Action on Aluminium Alloy.—An experiment of M. le Chatelier was described in a recent communication to the Académie des Sciences, which may have an important bearing. Equal parts of aluminium and copper were fused together in a crucible. The resulting ingot was then placed for 24 hours in a solution of common salt and lead chloride, with a view to dissolving out the uncombined aluminium. No apparent change could, at the end of this time, be observed in the ingot. It was accordingly removed from the saline bath, washed, and dried. At the end of 12 hours the whole mass was found to be reduced to the state of powder from the spontaneous oxidation of the alloy. A similar ingot, not immersed in the solution of sodium and lead chlorides, was unchanged at the end of a month.

A PLEA FOR THE ORGANISATION OF INVENTION.

Between the adoration of the inventor; as practised in America, and the distinct discouragement of him which is fashionable in England, there is a happy mean preferable to either extreme. The widely different attitude adopted towards men of many inventions on this side and on the other side of the Atlantic has its origin in the widely different circumstances and characteristics of the two peoples. The groove which our forbears have been good enough to cut for us is so broad, and has led us for so long in the right direction, that it seems to most Englishmen to smack of rank heresy, not to say gross disrespect, to suggest that the groove is also a deep one, and as difficult as it is desirable to get out of. This sleepy self-satisfaction results in a certain irritating obtuseness to new ideas, and, indeed, to novelty of any kind, which, although of no small utility in the painless repression of fads and faddists of all sorts and conditions, forms an atmosphere which is not exactly suited to the delicate constitution of the inventor. Even in those countries in which the inventor is encouraged by legislation and public opinion, and where invention is more or less organised and directed to definite ends, the principle of encouraging originality, admitted in theory, is with difficulty actually practised; the effort to grasp new conceptions, the discomfort of getting out of an old rut into a new one, is too severe for most of us to take to it kindly. In a country, then, in which there is not overmuch legislative encouragement of the inventor, and no general public encouragement whatever, the passive and active hindrances to invention become highly effective. Again, the typical inventor of the story-book and after-dinner speech, an individual who, it must be candidly confessed, has a real corporeal existence, is not calculated to win respect in any country where the narrow business spirit predominates. To begin with, the typical inventor is usually suffering from a very severe attack of enthusiasm; a grave disadvantage

Digitized by Google

where business bargains and the financial support of business men are the matters in hand. Furthermore he is, as often as not, completely ignorant of the industry which he has honoured with his attentions; nevertheless, he is almost fanatical in his faith in the efficacy of and necessity for his particular device, and as a fanatic is quite unable in the nature of things to give reasons for the faith that is in him, he fares badly in the hands of anyone wanting to know why it is absolutely necessary to adopt this or that improvement, and how long it will be before the returns come in. For the typical inventor, so called, it is impossible, indeed, to do more than obtain good-natured toleration. Many things, from the Salvation Army to German bands, are good-humouredly suffered by the great British Public, and the typical inventor would only be one more small addition to the very long list of irritants modern man is expected to endure without loss of temper. Typical inventors are certainly very trying, but then there is always about one chance in ten thousand that you may be contemptuously tolerating a Schwarz or a Gutenberg, which adds all the flavour of a mild Stock Exchange speculation to your magnanimous condescension.

It is not, however, the technically ignorant or wildly enthusiastic inventor that our good friends the Americans publicly worship. A dash of enthusiasm is indeed no disadvantage, nor for matter of that a little technical ignorance; an overtrained mind is not likely to possess the freshness requisite for genuine invention. Graham Bell, Elihu Thomson, Nikola Tesla—none of whom, by the way, are American born—are typical of the character, bent of mind, and genesis of the transatlantic inventor. An inventor is as much a part of the bag and baggage of a big American manufacturing or engineering company as a works manager, head draughtsman or chief estimating clerk. They do not use steam-hammers to crack nuts with out there, and inventive geniuses are not expected to waste the greater portion of their time in deadening routine work. Not only are the pecuniary rewards large, but inventions are not, as with us, usually labelled with the name of the reigning Sovereign, or any other pointless appellation, rather than endanger the inventor's peace of mind—and his fidelity to his employers—by connecting his name with the mechanism he has devised. Economically this severe suppression of the individual would seem somewhat short-sighted, since many would be content to take some of their reward in fame, which costs nothing. Of course, the ostentatious encouragement of invention which is so much *à la mode* in America has its reverse side. The legal facilities and forms ostensibly intended to stimulate and protect invention can be and have been made to serve quite other purposes. The much talked of poor inventor, unless he has, to use the phraseology of Emerson, "hitched his waggon to a star"—that is to say, to a big manufacturing concern or a millionaire speculator—fares but little better across the Atlantic than in this country, although, indeed, his fellow countrymen are considerably more predisposed in his favour. Concerns which enjoy a monopoly, whether in the United States or in the United Kingdom, do not, of course, encourage invention. They have, as a rule, paid huge sums for the patents which confer the monopoly, and their natural instinct is to sit quietly at the receipt of custom during the fourteen or seventeen protected years and trust that their long possession of the field will enable them to hold their own for many a year after the inventor is let loose upon them. But even in the case of monopolistic concerns, placing a straight waistcoat upon the inventive minds of the staff and a muzzle on their mouths defeats its own object in all but a very few exceptional cases. A monopoly with long-sighted men at its head might, by the judicious encouragement, and above all by the proper organisation, of the inventive spirits that are sure to be found amongst its employés, build up a new network of patents as fast as the old one wore out and thus perpetuate itself *ad infinitum*, and if it were to perpetuate itself in this manner its perpetuation would not be the unmixed evil it otherwise would certainly prove to be. Useful even as a means of maintaining a monopoly the organization of invention is invaluable as a weapon in competitive warfare. Concerns engaged in an industry where competition is keen do not indeed disdain the aid of the inventor, although with us he is not in most instances regarded as a separate organism, but is expected to work out his ideas in his leisure hours—if he has any—in much the same hap-hazard manner that a writer of Society verses dashes off his rhymes on the back of an envelope after dinner. This method, or rather lack of method, without doubt achieves one end. The percentage of unqualified failures is extremely small. It cannot, however, be considered conducive to epoch-making inventions, and it is to be questioned whether our present plan of graciously permitting foreigners to invent what we condescend to subsequently apply and improve is one which will lend itself indefinitely to the preservation of our industrial supremacy.

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(Continued from page 327.)

§ 47. **Capacity Tests** (*continued*)—With further reference to the "earthing period," previously mentioned, the Saunders key can be used in a manner to make this period anything desired, although provided as described with the arrangement to make the period as small as possible. The earthing period is, of course, the time elapsing between raising the charge key and putting down the discharge key. Mr. Arthur Dearlove's above-mentioned article, which will repay careful study, shows that the earthing period had an important influence on the accuracy of the correction: if insufficient time was allowed the cable was not properly discharged, and the correction became too large, making the apparent capacity too high. The tests were taken on laid cables of 1,331 and 100 knots respectively, and the true capacity per knot was taken as that determined on two-knot lengths at the factory, at a temperature of 75°F. The cables were each balanced against condensers of 20 and 60 microfarads capacity. On the large cable the mean of the tests gave an excess of only four-fifths of one per cent. over the true capacity as measured in factory lengths. This on a cable of 472 microfarads must be admitted to be a very good proof of the usefulness of the Muirhead correction. The earthing period allowed was three seconds, and it was found that a less period complicated matters, as the absorption discharge was then first in one direction and then in the other. In such cases the *difference* only was taken as the correction to apply, but the author of the Paper points out that this effect may be used as a means of finding the right time necessary for the "earthing period" for any length of cable. For the purpose of verifying the accurateness of the correction, the periods of "charge" were varied from 5 to 60 seconds, and it was found that the correction became somewhat too powerful with periods exceeding 30 seconds. The normal period of charge need not, in the ordinary course, exceed about 5 seconds on the longest cables, but it is gratifying to know that this time may be extended to 30 seconds without lessening the accuracy of the correction, as it allows more time to balance the slides.

One cannot fail to notice in these results that the apparent or uncorrected capacity is *less* than the true in all the tests on the long cable and *more* than the true in all tests on the short cable. Looking for some reason to account for this we find that the tests on both cables were made with the same standard condensers, the insulation resistance of which were about seven megohms per 60 microfarads, or about 420 megohms per microfarad. Turning now to the insulation resistance and capacities of the cables, these are given as one megohm for the 1,331-knot cable and six megohms for the 100-knot length, the true capacities being 0·352 and 0·354 microfarads per knot respectively. The insulation resistance of the long cable was therefore

$$1{,}331 \times 0{\cdot}352 \times 1 = 470 \text{ megohms per microfarad,}$$

or about the same as that of the standard condensers used with it in the tests. On the other hand the insulation resistance of the 100-knot cable was

$$100 \times 0{\cdot}354 \times 6 = 212 \text{ megohms per microfarad,}$$

or only about half that of the standard condensers.

It appears therefore that the uncorrected tests make the apparent capacity of a cable *less* than the true when the insulation resistance of the cable per microfarad *exceeds* that of the condenser tested with it, and *more* than the true when the resistance is *less* than that of the condenser.

From this it appears that, with a certain relation between the insulation resistances per microfarad of the cable and condenser (possibly when equal, or nearly so), the apparent capacity, as given by the test, will be the true capacity, and needs no correction. The author of the Paper has also pointed out that the correction for absorption may become very small when the insulation resistance of the two capacities compared is about the same per microfarad. Mr. E. C. Rimington has also shown mathematically (*Phil. Mag.*, September, 1887) that in comparing capacities by Gott's method the insulation resistance of the cables or condensers compared must be known, and if unequal allowed for in the formula.

The *equalisation* of the insulation resistances per microfarad of the capacities under comparison has fortunately been tried on cables of different lengths with excellent results, shunting either the condenser or cable as necessary; and it has been found that this brings the apparent capacity equal to the true within sufficiently accurate limits, no correction being then required. The method and results are published in a Note to *The Electrician* of February 5, 1892, p. 361, signed by "F. W.," of Alexandria, Egypt. Taking the first example cited in this Note, the cable (of 910 knots) had an insulation resistance of 0·63 megohm and a capacity of 280 microfarads; that is,

$$280 \times 0{\cdot}63 = 176 \text{ megohms per microfarad,}$$

while the condenser used in the test with this cable measured 10 megohms and 99 microfarads; that is,

$$10 \times 99 = 990 \text{ megohms per microfarad.}$$

To make the insulation per microfarad of the condenser equal to that of the cable (176) it is clear that the absolute resistance of the condenser must be

$$\frac{176}{99} = 1{\cdot}78 \text{ megohms.}$$

The condenser was accordingly reduced to this insulation by shunting it with a resistance of $\frac{10 \times 1{\cdot}78}{10 - 1{\cdot}78} = 2{\cdot}16$ megohms, the result being a perfect balance on the slides—that is, the absorption discharge being *nil* and no correction being required. The apparent capacity was then equal to the true capacity within 0·03 per cent.

Another case is cited in which the insulation resistance per microfarad of the cable was *higher* than the condenser; and, notwithstanding that the insulation had to be reduced by an artificial leak at the home end, the test showed the apparent capacity equal to the true within as close a limit as 0·4 per cent. The figures in this were

Cable (331·8 knots)	2·5 megohms and	97 microfarads,
Condenser	0·41 „	59·448 „

The condenser was therefore

$$0{\cdot}41 \times 59{\cdot}448 = 24{\cdot}25 \text{ megohms per microfarad.}$$

The cable resistance had to be reduced (by the artificial leak) to

$$\frac{24{\cdot}25}{97} = 0{\cdot}25 \text{ megohms}$$

to have the same insulation per microfarad as the condenser.

Considering, now, the application of this method to Gott's test, in which it is desired to determine the true capacity of a given cable, the *modus operandi* would be to obtain the balance first in the ordinary way on the slides, and then to adjust the shunt on the condenser (or artificial leak on the cable) until the absorption discharge is *nil*. Then the slide reading n is the correct one to give the true capacity in the formula

$$\text{Cable capacity} = F\left(\frac{10{,}000}{n} - 1\right) \text{ microfarads,}$$

where F is the capacity of the condenser. Generally the approximate capacity of the cable will be known and the shunt can be adjusted very nearly beforehand. Condensers in fairly good condition have generally a higher insulation per microfarad than cables that have been laid some time, and it will usually be found that the shunt has to be applied to the condenser. This method, which the writer of the Note ("F. W.") terms the double-zero method, is simple and accurate, and should prove of considerable utility in the determination of the true capacity of cables, which is of so much importance in furnishing data for the localisation of faults.

In an interesting communication to *The Electrician* (Dec. 12, 1890, page 168) on this subject, Messrs. Harold W. Ansell and Julian E. Young direct attention to the important part played by the insulation and retardation of a submerged cable in the discrepancies that occur between the apparent and true capacity. The authors of this Paper show that, when balancing against each other condensers with similar dielectrics, and therefore having similar rates of absorption, there is still a considerable error to be accounted for, if only a moderate leakage exists on one of the condensers. A very interesting method is given for determining the correction for insulation resistance and retardation of a cable—that is, a correcting factor for deriving the true capacity from the apparent. This factor is arrived at by a consideration of the time of charge, and the approximate insulation and capacity of the cable. The true capacity is proportional to the instantaneous charge, as in a condenser or a short length of a knot or two of cable; but when a long submerged cable is being tested, a certain time must be allowed for the charge to reach and attain its full value at the distant end. Letting K stand for the ratio of the full charge to the instantaneous charge, we have, by Siemens law of the fall of charge,

$$\log K = \frac{t}{2{\cdot}3026\, F R},$$

where F is the capacity of the cable in microfarads, R the insulation resistance in megohms, and t the time of charge in seconds. Assuming the ratio of the apparent to the true capacity to be the same as the ratio between the final and instantaneous charges, at the distant end, we have

$$\text{true capacity} = \frac{\text{apparent capacity}}{K}.$$

The value of the ratio K having been found from the above expression by inserting approximate values for F and R, and putting t the time of charge in seconds, the true capacity is found by dividing the apparent capacity by this number.

The authors balanced condensers of approximately 20 and 80 microfarads against each other, one of them having a leak artificially applied varying from ½ to 3 megohms. The results show that the apparent capacity increased considerably as the insulation resistance was reduced, but that the application of the correction gave the true capacity to within one-half of 1 per cent. The periods of charge were varied from 2 to 15 seconds.

(To be continued.)

The French Association for the Advancement of Science.—The twenty-fourth meeting of this Association is to be held at Bordeaux from the 4th to the 9th prox.

SCIENTIFIC USES OF LIQUID AIR.*

BY PROF. DEWAR, F.R.S.

When Faraday was working on liquid gases in this Institution about 1823, with such means as were then at his command, his inquiry was limited to the determination of the specific gravities and vapour pressures of such bodies. Twenty years later, by the use of solid carbonic acid, the greatest cold then possible was obtained, and Faraday made admirable use of Thilorier's new cooling agent to extend his early investigations. Just as liquid carbonic acid produced in glass tubes was of no use as an agent for effecting the liquefaction of more resisting gaseous matters, until it could be manipulated in the solid state, so liquid air, until it could be handled, stored and used in open vessels, like any ordinary liquid, could not be said to possess scientific uses in any wide sense. Such operations become easy when double-walled vacuum vessels (such as were described in a former lecture) are employed in the conduct of experiments where substances boiling at very low temperatures have to be manipulated. The chief scientific use of liquid air consists in the facilities it gives for the study of the properties of matter at temperatures approaching the zero of absolute temperature. In this lecture the expression liquid air may mean either oxygen or air. Where a constant temperature is required oxygen is used. Liquid air made on the large scale may contain, after it is collected in open vacuum vessels, as much as 50 per cent. of oxygen. Such a liquid boils between −192°C. and −182°C., and the longer it is stored the nearer it comes to −182°C., or the boiling point of pure oxygen. For a number of experiments of a qualitative character, whether it is liquid air or oxygen that is used makes no difference. In many of the experiments to be recorded, liquid oxygen made from the evaporation of liquid air was employed. In pursuing this subject in consort with Prof. Fleming,† a long series of experiments, involving the use of large supplies of liquid oxygen, have been carried out on the electric resistance of metals and alloys, and the results warrant the conclusion that at the zero of absolute temperature all the pure metals would be perfect conductors of electricity. Under such conditions a current of electricity started in a pure metallic circuit would develop no heat, and therefore undergo no dissipation. Similarly, we infer there would be no Peltier effect at the zero. In other words, the passage of electricity from one metal to another would take place without evolution or absorption of heat.

Further investigation, along with Prof. Liveing,‡ on the refractive index of liquid nitrogen and air, has led to the conclusion that the refractive indices of nitrogen and air are respectively for the D-ray, 1·2053 and 1·2062. In these determinations, instead of using the prisms we have employed the method of Terguem and Trannim, which consists in suspending in the liquid two plates of glass with a thin layer of air between them, and measuring the angle of incidence at which the chosen ray suffers total reflection at the surface of the air. As all the vacuum vessels are either spherical or cylindrical in form when filled with liquid, they act as lenses which are irregular and full of striations. Further, small bubbles of gas being given off in the liquid rendered any image indistinct when viewed with a telescope. In order to avoid the necessity of observing any image through the liquid, it was used simply as a lens to concentrate the light observed on the slit of a spectroscope. Under such conditions the observations were easily executed, and the results satisfactory.

For some time a series of observations on the thermal opacity of liquid oxygen and nitrogen have been projected. It is, however, exceedingly difficult to experiment in such a way as to eliminate the absorbing action of the glass vessels, and as the use of rock salt is impracticable, the absorption of heat of low refrangibility remains for the present undetermined. It is possible, however, to use the glass vacuum vessels to determine approximately the relative thermal transparency for heat of high refrangibility, such as is radiated by a colza lamp. The following results represent the heat transmitted through the same vacuum vessels filled with different liquids, taking chloroform as the unit for comparison and correcting for differences of refractive index :—

Chloroform	1·0
Carbon bisulphide	1·6
Liquid oxygen	0·9
Liquid nitrous oxide	0·93
Liquid ethylene	0·60
Ether	0·50

From this result it follows that liquid oxygen is nearly as transparent to high temperature heat radiation as chloroform, which is one of the most transparent liquids next to carbon bisulphide. Liquid ethylene is much more opaque. These results must, however, be considered only as an approximation to the truth, and as generally confirmatory of the inferences Tyndall drew as to the relation between gases and liquids as absorbents of radiant heat.

Instead of silvering the interior and exterior of the vacuum vessels, it is found convenient when using mercury vacua to leave a little excess of liquid mercury, in order that the act of filling the inner vessel with liquid air should cause a fine silvery deposit of the metal over the exterior surface of the inner vessel. In such a vessel liquid air or oxygen shows no signs of ebullition, the surface remains as quiet and still as if it was ordinary water. The supply of heat is cut down to less than 4 per cent. of what it is without exhaustion and silvering in good vacuum vessels. The result is that volatile liquids can be kept 30 times longer. Such vessels do not, however, maintain indefinitely the high standard of heat isolation they possess the first time they are used. After repeated use all vacuum vessels employed in the storage and manipulation of liquid air deteriorate. Illustrations of the appearance of such vessels are given in Figs. 1 and 2. The rapidity with which a space is saturated with mercury vapour (which we know exerts a pressure of about one-millionth of an atmosphere) is easily proved by simply filling a barometer in the usual way, and then instantly applying a sponge of liquid air to a portion of the glass surface of the Torricellian vacuum space, when a mercury mirror immediately deposits. It is important to know the amount of mercury deposited from a saturated atmosphere which is maintained (containing excess of liquid mercury) at the ordinary temperature, the condensation taking place when liquid air or oxygen is discharged into a vessel surrounded by such a Torricellian vacuum. If the deposit on the cooled bulb is allowed to take place for a given time, the outer vessel can then be broken

FIG. 1.—Vacuum Vessel for Storage of Liquid Air.

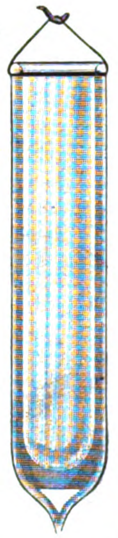

FIG. 2.—Vacuum Vessel for Storage of Liquid Air.

and the amount of mercury which coated the bulb ascertained by weighing. Knowing the surface of the cooled bulb, the amount deposited per unit of area can be calculated. In this way it was found that in ten minutes two milligrammes of mercury per square centimetre of surface was deposited. Considering that one-tenth of a milligramme of mercury in the form of saturated vapour at the ordinary temperature corresponds to the volume of 1 litre, this proves that the equivalent weight of 20 litres had been condensed in the space of ten minutes. This plan of cooling a portion of the surface of a vessel by the application of a liquid air sponge, enables us to test our conclusions as to the amount of matter present in certain vacua. Here is a globe of the capacity of 1 litre. It has been filled with, presumably, nothing but the vapour of mercury, by boiling under exhaustion and subsequent removal of all excess of liquid. Such a flask ought to contain mercury in the gaseous state that would weigh rather less than one-tenth of a milligramme, assuming the ordinary gaseous laws extend to pressures of less than one-millionth of an atmosphere. Now we know by electric deposition than one-tenth of a milligramme of gold can be made to cover 1 sq. cm. of surface with a fine metallic deposit. Considering the general similarity in the properties of mercury and gold, we should therefore anticipate that if all the mercury vapour could be frozen out of the litre flask it would also form a mirror about 1 sq. cm. in area. But after one such mirror is deposited the renewed application of a second liquid air sponge to another portion of the surface would cause no visible deposit. This is exactly what takes place. If, however, two spheres, one much larger than the other, are joined together by means of a

tube about 2mm. in diameter and 50mm. long, the whole space being a Torricellian vacuum (with some excess of mercury) then on decanting, the mercury may be transferred to the smaller sphere, as is represented in Fig. 3. Now if an air sponge is applied to a portion of the surface of the larger sphere, a mercury mirror instantly deposits, but on applying a new air sponge to another portion of the surface, no further mercury mirror is formed. The narrow glass tube prevents the excess of liquid mercury in the small bulb supplying vapour rapidly to the larger one, so that the local cooling to $-180°$C. of a portion of the surface has practically condensed all the mercury in the larger space, although the small one is still filled with saturated vapour and a free communication exists between them. If while in this condition the small bulb is inclined so as to allow a drop of liquid mercury to fall into the lower side of the large bulb, which has not been cooled, instant deposition of mercury takes place on the liquid air cooled portion of the upper surface. Under very small pressure of vapour, therefore, equalisation of pressure of two bulbs communicating by a narrow tube is a very slow process.

There are cases, however, in which the application of a sponge of liquid air to the surface of a vessel causes no visible deposit, and yet the inference is that something has been condensed. The best arrangement to show this effect is to select highly exhausted vacuum tubes containing phosphorescent materials like alumina and other minerals, and to arrange the induction coil spark gap of a little greater resistance than the vacuum tube. On starting the coil the

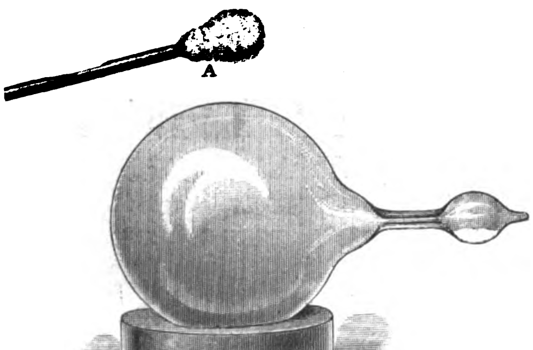

FIG. 3.—Deposit of Mercury Vapour by cooling with Liquid Air.

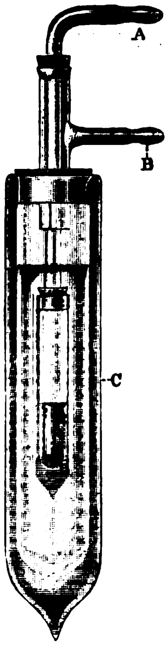

FIG. 4.—Vessel for keeping Liquid Air without Evaporation.

current passes slowly by the vacuum tube, but immediately the liquid air sponge cools a portion of the surface of the bulb, the discharge shifts to the air-gap. During the cooling the phosphorescence of the glass tube is greatly increased, but finally the resistance may become so great that all discharge in the vacuum tube ceases. Some old tubes belonging to the late Dr. de la Rue have given visible deposits near the electrodes, and in many the diameter and distribution of the striæ are materially changed during the local cooling to $-190°$C. When large vessels containing nothing but mercury or iodine vapour as a residuum of the vacuum space are rubbed with a cotton wool sponge of liquid air in a dark room, luminous glows filling the vessel take place occasionally, or bright flashes of light which enable the shape of the vessel to be seen. The ordinary mercury vacuum vessels show the same phenomena, which is doubtless due to electric discharges caused by friction and cooling.

The optical properties of bodies cooled to the temperature of boiling liquid air will require long and patient investigation. An interesting fact easily observed is the marked change in colour of various bodies. Thus, for instance, oxide, sulphide, iodide of mercury, bichromate of potash, all become yellow or orange, while nitrate of uranium and the double chloride of platinum and ammonium become white. Chromic acid, dilute solution of iodine in alcohol, strong solutions of ferric chloride, and other coloured solutions become greatly changed. Such facts are sufficient to prove that the specific absorption of many substances undergoes great changes at the temperature of $-190°$C.

The tranquil atmosphere of air above the surface of the liquid in cylindrical or spherical vacuum vessels is a convenient place to cool very fragile bodies. During the slow ebullition of the fluid, gas between $-190°$C. and $-180°$C. is given off, which has three times the density of ordinary air, and which falls slowly over the mouth of the vessel in a heavy stream. On dipping into this atmosphere small soap bubbles, they contract rapidly and then freeze. If a soap film is made on a circle of thin wire about 2in. in diameter, and allowed to stand until it shows the various orders of coloured bands, and is then carefully dipped into the cool air, it freezes, showing all the original colours. The black band is, however, always broken. Speaking of films, an interesting experiment may be made with a thin stretched sheet of india-rubber, such as is used for making balloons. It is well known that stretched india-rubber contracts when heated and expands when cooled. Now this can be shown very easily by covering a glass funnel or the end of a cylindical vessel with a stretched sheet of rubber as thin as the walls of balloons. Such a surface is quite flat, and fairly transparent. If a sponge of liquid air is drawn across the surface, the course is marked by a series of wrinkles, due to the temporary expansion of the rubber caused by the extreme cold. The sheet of rubber, being extremely thin, soon regains the ordinary temperature, and the surface then is as flat and tense as before. During the continuous motion of the cotton wool liquid air sponge over the rubber surface, it is followed by wave-like depressions, which disappear almost as quickly as they are formed. The elasticity of india-rubber, after cooling to $-182°$C, and reheating, seems unimpaired.

Organic substances that only become solid at very low temperatures may be divided into two classes: those which crytallise, and those which form glasses. Thus, bisulphide of carbon, tetrachloride of carbon, methyl alcohol, hydride of amyl, all form crystals, whereas ethyl alcohol, amyl alcohol, turpentine, ethyl nitrate, chinoline, picolin, are glass-like. If a few dops of bisulphide of carbon are added to alcohol, and the mixture cooled to $-180°$C., a white solid emulsion is formed, whereas the addition of tetrachloride of carbon to the alcohol resulted in the production of a clear solid without any separation. In the same way pure methyl alcohol crystallises easily, but the addition of a few drops of ethyl alcohol prevents crystallisation, and causes a glass to be formed. Thus the examination of the behaviour of organic bodies at low temperatures may be a fruitful means of organic investigation.

For many purposes of investigation it is necessary to keep liquid air without evaporation. This is readily done by the use of two vacuum test tubes, fitting freely one inside the other, arranged as in Fig. 4. The smaller one is filled with liquid air, and after the insertion of an india-rubber stopper and glass tube, is completely immersed in liquid air contained in the larger vacuum vessel. In the figure the tube A connects with the inner vacuum tube and B with the outer. As the latter receives all the radiant and conducted heat, air is continuously boiling off through the tube B; but as the supply of heat is effectually cut off from the inner vacuum vessel, also containing liquid air, no air distils through tube A. This is the most convenient arrangement to use for the production of solid air. For this purpose B is connected with an air pump until the pressure is reduced to about $\frac{1}{10}$in., and therefore the temperature about $-200°$C. Then a good air pump is put on to the inner vessel of liquid air (containing oxygen and nitrogen in the normal proportion of oxygen and nitrogen) by means of the tube A, while maintaining constantly the exhaustion in the outer vessel. In a short time the air in the inner vessel solidifies to a transparent jelly-like mass.

The same principle is used when the latent and specific heats have to be determined. Fig. 5 shows the general plan of the apparatus. Now a definite quantity of heat has to be conveyed into the inner vacuum vessel containing liquid air, with the object of finding the weight of liquid that distils off on the one hand, or the elevation of temperature in the liquid that takes place on the other. For the purpose of adding a given quantity of heat it is convenient in some cases to use mercury (as represented in the figure), or to lower a piece of platinum or silver, or even glass, into the inner vessel; each unit of heat supplied evaporates a definite amount of air, which is readily ascertained by collecting the gas which comes off during the heat conveyance. In Fig. 5, A is the mercury, C the inner vessel of liquid air, D a three-way stop-cock, F a tube for collecting the air given off; E is a barometric tube for observing the pressure when the inner vessel is exhausted. In a latent heat determination all that is necessary is to weigh the mercury added, and to measure the amount of air by volume which has distilled from the liquid state. If the specific heat of the liquid is wanted, then the inner vessel is exhausted (as well as the outer) through the tube F to about $\frac{1}{10}$in. pressure, and the three-way stop-cock turned so as to shut off F and connect the inner vessel with the manometer E. Mercury is now dropped into the inner vessel until the manometer rises to the atmospheric pressure or the liquid reaches its boiling point under atmospheric pressure. Care must be taken to prevent the drops of mercury

Digitized by Google

falling exactly in the same place, otherwise a mercury stalagmite grows up rapidly through the liquid, vitiating the results. Another objection to the use of mercury arises from the drops causing the rebound of small liquid air drops, which strike the cork and get evaporated away from the main body of liquid. The amount of mercury added conveys the necessary amount of heat needed to raise the given amount of liquid from its boiling point under ½in. pressure to its boiling point under 30in. The relative pressures give the temperature range, and the weight of liquid air or other gas under observation is easily ascertained, together with the weight of mercury added. In this way the latent heat of liquid oxygen at its boiling point is about 80 units, and the mean specific heat between –198deg. and –182deg. is 0·39.

Seeing that the most powerful chemical affinities are in abeyance at very low temperatures, it is a matter of great interest to ascertain what change comes over the physical force we name cohesion.

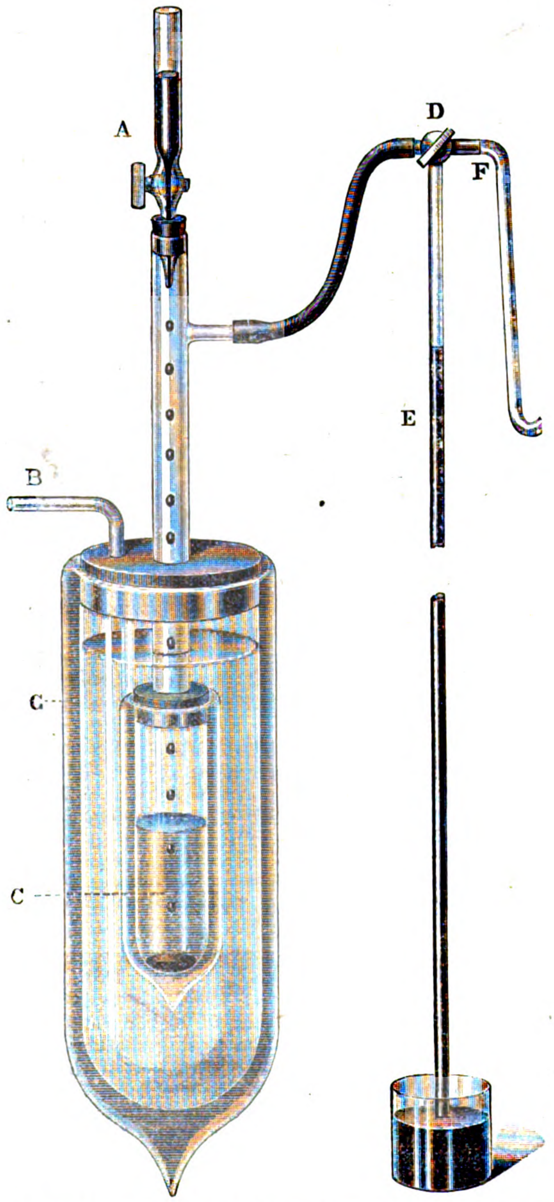

FIG. 5.—Apparatus used in the determination of the Latent and Specific Heat of Liquid Air, &c.

Here we are dealing with the molecular forces which are effective in uniting together the particles of solid bodies, in contrast to the force we name chemical attraction, which exists most characteristically between dissimilar molecules. Both are alike in this respect, that they are insensible at sensible distances. If we accept the theory of matter which regards finite heterogeneousness of the most homogeneous bodies as proved, then Lord Kelvin has shown that gravitation alone would account for the so called cohesive forces. Thus, he says ("Popular Lectures," Vol. I. page 60): "But if we take into account the heterogeneous distribution of density essential to any molecular theory of matter, we readily see that it alone is sufficient to intensify the force of gravitation between two bodies placed extremely close to one another, or between two parts of one body, and therefore that cohesion may be accounted for without assuming any other force than that of gravitation, or any other law than the Newtonian." Another view of the cohesive forces is taken by Mr. S. Tolver Preston, in his work entitled "Physics of the Ether," page 64. He says, "The phenomena of 'cohesion,' 'chemical union,' &c., or the general phenomena of the aggregation of molecules, being dependent on the molecular vibrations as a physical cause, it would therefore be reasonable to conclude that variation of vibrating energy (variation of 'temperature') would have a most marked influence on these phenomena, as is found to be the fact. Further, since when a physical cause ceases to exist the effect also ceases, it follows that at the absolute zero of temperature (absence of vibrating energy) the general phenomena of 'cohesion,' including the aggregation of molecules in chemical union, would cease to exist." If this theory is pressed so as to include the gaseous state, then at the temperature of –274°C. we may imagine the particles reduced to an incoherent layer of dust or powder. The experimental facts do not, however, warrant this conclusion, seeing that at the lowest temperature reached, which is about –210°C., air remains a transparent jelly.

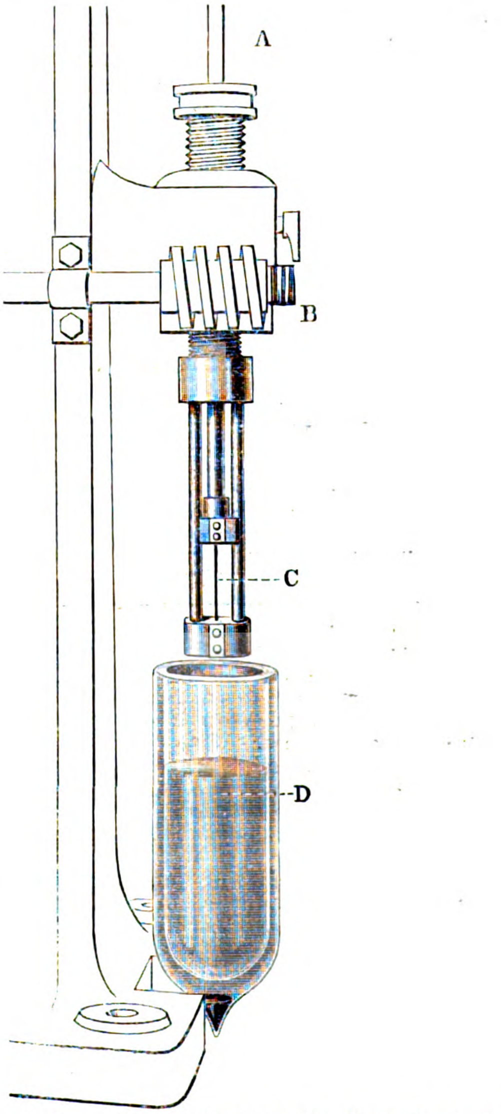

FIG. 6.—Apparatus used for testing the alteration in the Elastic Constants of Metals at Low Temperatures.

That a low temperature causes profound changes in the elastic constants of a metallic body is most easily shown by placing a rod of fusible metal in liquid air, and comparing the deflection produced by a weight when the rod is supported at one or both ends before and after cooling. The Young modulus is increased to between four and five times its amount at ordinary temperatures. In the same way, the rigidity modulus can be shown to be greatly changed by cooling a spiral spring made of fusible metal wire. Such a spring at the ordinary temperature is quickly drawn out into a straight wire, by attempting to make it support an ounce weight. The same spiral, cooled to –182°C., will support a couple of pounds, and will vibrate like a steel spring so long as it is cool. In the same way, a bell or tuning fork of fusible metal gives a

Digitized by Google

distinct metallic ring at - 180deg. If two tuning forks are taken of identical pitch, and one cooled to - 182deg., then on simultaneously striking them beats are very distinctly heard. The simplest plan of getting some idea of the change in the cohesive force at low temperatures, is to ascertain the tenacity or breaking stress of the metals and alloys under such conditions, and to compare such results with similar experiments made at the ordinary temperature with the same metallic samples, using the same apparatus. In this way the comparative values are reliable. The only difficulty is the large quantity of liquid air or oxygen required to cool the steel supports of the wires, which have to be broken. Seeing that wires less than one-tenth of an inch in diameter are unreliable, good strong rigid steel supports are needed, and as these have to be cooled each time a wire is broken, the experiments involve large quantities (gallons) of liquid air and oxygen. Further, as not less than three, and in many cases six experiments must be made with each sample of wire, and the stress in each case can only be applied slowly, work of this kind extends over long periods of time, and this means increased waste of liquid gases. Fig. 6 shows the general plan of the part of the testing machine which supports the wires which have to be broken. In the figure, A is the steel rod which is connected to the multiplying levers, the stress being gradually increased as usual by running in water into a vessel hung from the long end of the lever; C is the wire to be tested, B is an arrangement which measures roughly the extension of the wire, and D is a large silvered vacuum vessel holding the liquid oxygen. This latter vessel must be large, in order to avoid any part of the supports of the wire coming into contact with the sides, otherwise the shock of the wire on breaking shatters the vacuum bulb. The rupture must be made while the wire is immersed in the liquid oxygen, and the whole of the supports thoroughly cooled down. The wires must be caught in long V-shaped grooves made in the steel supports in order to avoid slipping, and change in the cross-section of the wire. As a rule, the wires used were one-tenth of an inch in diameter and 2in. long. The following table gives the mean results of a large number of experiments:—

Table I.—*Breaking Stress in pounds of Metallic Wires 0·098in. diameter.*

—	15°C.	-182°C.
Steel (soft)	420	700
Iron	320	670
Copper	200	300
Brass	310	440
German silver	470	600
Gold	255	340
Silver	330	420

An inspection of this table proves that all the common metals and alloys increase in tenacity at low temperatures: thus iron has doubled its breaking stress, and the other metals and alloys are all increased from a third to a half the normal amount. This increase of strength is solely due to the low temperature, and persists only during its continuance. Wires that have been cooled to the temperature of - 182°C. and allowed to regain the ordinary temperature, are in no way changed as regards their breaking stress.

A second series of experiments were made with a set of cast test pieces of metals and alloys. The test pieces, all cast in the same mould, were 2in. long with ½in. spherical ends, the cylindrical portion being two-tenths of an inch in diameter. The spherical ends of the test pieces rested in similar cavities made in a special set of steel supports that fitted on to the testing machine. Crystalline metals give castings that are far from uniform one with another, and it is very difficult to get even comparable results with metals like zinc, bismuth and antimony. The following table gives the experimental results:—

Table II.—*Breaking Stress in pounds of Cast Metallic Test Pieces. Diameter of rod 0·2in.*

—	15°C.	-182°C.
Tin	200	390
Lead	77	170
Zinc	35	26
Mercury	0	31
Bismuth	60	30
Antimony	61	30
Solder	300	645
Fusible metal (Woods)	140	450

It will be noted that in this list the breaking stress, by cooling to - 182°C., has been increased to three times its usual value in the case of fusible metal, and to twice its usual value in the case of tin, lead and solder. The results with zinc, bismuth and antimony are exceptional, seeing they appear to be diminished in tenacity. This, however, may be only apparent, because the stresses set up in cooling such highly crystalline bodies probably weaken some set of cleavage planes so that rupture is then comparatively easy. In any case it must be admitted that no reliance can be placed on the tenacity of highly crystalline metals. The breaking stress of mercury is interesting, and turns out to be at - 182°C. nearly half that of lead at the ordinary temperatures.

The percentage elongation is not given in the foregoing tables, simply because the value of such measurements is of little importance when such short pieces of the metals are under observation. The general results of such observations are, however, interesting; thus, lead and tin at ordinary temperatures elongate before breaking about the same amount, whereas if tin is cooled to - 182°C. it hardly shows any extension, and lead under such conditions shows no change, stretching as much at - 182deg. as at 15°C. Solder and fusible metal stretch less, and the cross-section of the break is much less at - 182deg. than at 15°C.

The above experiments can only be considered as preliminary to a more elaborate investigation of the actual variation of the elastic constants at low temperatures. It will require complex experimental arrangements to get reliable measurements of the Young modulus and the rigidity modulus at the temperature of boiling liquid air. In the case of fusible metal, a first attempt to compare the ratio of the Young modulus at 15deg. and - 182deg. with the ratio of the rigidity modulus between the same limits of temperature, has resulted in finding that both constants are increased in the same proportion. From this it would follow that the resistance to compression of the substance at - 182°C. must be increased in a similar ratio. The comparative behaviour of strong steel spirals at 15°C. and - 182°C. as to their elongation on the repeated addition of the same load was a subject examined on several occasions. The most careful comparison of such spirals, however, revealed no measurable differences in their elongation between the ordinary temperature and that of boiling oxygen. This may be due to the want of sufficient sensibility in the testing machine when applied to such delicate experiments. In the meantime it is reasonable to conclude that the rigidity modulus of very hard steel is not much changed by cooling it to - 182°C. If balls of iron, tin, lead or ivory are cooled to - 182°C. and dropped from a fixed height on a massive iron anvil the elastic rebound is markedly increased in all cases. The flat distortion surface produced on the lead sphere after impact is only one-third the diameter of the circular surface produced at the ordinary temperature when the lead ball falls from the same height.

The examination of the magnetic condition of matter at low temperatures is a subject of great interest and offers a wide field for investigation. In a former lecture the magnetic properties of liquid oxygen and air were discussed. Owing to the experimental difficulties, accurate quantitative measurements of the permeability have not yet been successful. Faraday was the first experimenter who examined the magnetic condition of matter at the lowest temperature that could be commanded in his time, viz., about - 110°C. He did not succeed in making any substance which was non-magnetic at ordinary temperatures assume the magnetic state at the lowest temperature of the solid carbonic ether bath in vacuo. Later experimenters have directed their attention more especially to the action of high temperatures on magnetism, and the work of Profs. Hopkinson and Ewing in this field of research is well known. Prof. Trowbridge examined the effect of a temperature of - 80°C. on a permanent magnet, and came to the conclusion that the magnetic moment was diminished by about 50 per cent. Prof. Ewing found that an increase of temperature of 150°C. above 10deg. caused a reduction of the magnetic moment of a bar magnet by about 40 per cent., and that the magnet on cooling recovered its original state. This result would lead us to expect that if the same law is followed below the melting point of ice as Ewing found above it, then a bar magnet cooled to - 182°C. ought to gain in magnetic moment something like 30 to 50 per cent. The experiment of Prof. Trowbridge is, however, apparently opposed to such an inference. It appears, however, that Prof. Trowbridge cooled a magnet that had not reached a constant state (that is to say, one that on heating would not have completely recovered its magnetisation on cooling), because after the magnet had been cooled to - 80deg. on regaining the ordinary temperature, it had lost 50 per cent of its original magnetic moment. Such a magnet would apparently diminish in magnetic moment on cooling and heating the first time the action was examined, but a repetition of the process when the action of magnetisation and temperature were strictly reversible might lead to an opposite conclusion. To settle this question a series of experiments on the magnetic moment of small magnets cooled to - 182deg. were carried out. Small magnets from half an inch to an inch in length were made of watch-spring or steel wire, and were either used separately or in bundles; they were fixed rigidly in a block of wood by means of copper staples, and in this condition were easily clamped firmly in the field of a magnetometer. The cooling was effected by applying a cotton-wool sponge of liquid air. The relative deviations of the

Digitized by Google

magnetometer are proportional to the magnetic moment of the magnet under the respective conditions of +15°C. and −182°C. After the first cooling the magnet is allowed to regain the ordinary temperature, and the operation of cooling and heating is repeated three or four times. The following table gives some of the results, and these may be taken as typical of a large additional number unrecorded.

If the experiment marked (1) is examined we find cooling to −182deg. in the first cycle produced no change of magnetic moment, but that on heating to +15°C. the magnet had lost 30 per cent. of the original strength. In the second cycle cooling increased the magnetic strength of the magnet, in the condition in which it is left after the first cooling by 33 per cent., and heating diminished it by 5 per cent.; whereas in the third cycle cooling showed 36 per cent. increase, and no loss in heating. It was only after three alterations of temperatures from +15°C. to −182°C. that the magnet reached a steady condition. In experiment (3) the first cooling shows a loss of 24 per cent., while in experiment (4) the first cooling shows a gain of 12½ per cent.

Change of the Magnetic Moments of Permanent Magnets at +15°C. and −182°C. per cent. of the value at the beginning of each cycle, which is always 15deg.

It is clear, therefore, that according to these experiments, every magnet has individual characteristics that may either result in no change on cooling or the addition or subtraction of from 12 to 24 per cent. in the magnetic strength. All the experiments, however, show that a repetition of the cycle of heating and cooling brings the magnet to a steady state, in which cooling always causes increase in the magnetic strength of from 30 to 50 per cent., and the re-heating brings about no loss in the original magnetic moment. Such a marked alteration of magnetic strength might be used as a thermometer in low temperature research, and it is my intention to extend the inquiry to the lowest temperature that can be reached by the evaporation of nitrogen in vacua. A simple mode of showing the sudden alteration of magnetic strength on cooling is to surround a permanent magnet made up of a bundle of steel wires with a coil of copper wire, leaving the ends of the magnet to project so that they can be dipped in liquid air. When the copper wires are attached to a galvanometer, and one of the ends of the magnet cooled, an induced electrical current occurs, due to the sudden magnetic change. Accurate observations must be made on the permeability and susceptibility of the magnetic metals at the temperature of boiling liquid air, and the above results are an indirect guarantee that this field of investigation will be fruitful in new scientific facts.

This lecture has already covered a very wide field. It is easy to put into a Friday evening discourse the work of a year. Members and friends have chiefly contributed to the research fund, which has enabled the Institution to extend the experimental plant needed for the prosecution of research in this field of inquiry, and they have strong claims to learn, in the first instance, the results of the general laboratory work. My object has been to illustrate the scientific uses of liquid air. To do this with any satisfaction requires what may be called a good deal of scientific prospecting. It is one thing to discover where the ore lies, it is another thing to produce the refined metal. Investigations on the properties of matter at the temperature of boiling liquid air, must be in the first instance rather qualitative than rigidly quantitative. In my opinion, scientific progress is best served by conducting the inquiry on these lines. It will be easy to refine later on.

I have to acknowledge the great assistance I have received in the conduct of these experiments from my excellent chief assistant Mr. Robert Lennox, and I must also express commendation of the way Mr. Heath has helped in the work.

THERMO-ELECTRIC POWERS OF METALS AND ALLOYS BETWEEN THE TEMPERATURES OF THE BOILING-POINT OF WATER AND THE BOILING-POINT OF LIQUID AIR.*

BY PROFS. JAMES DEWAR, F.R.S., AND J. A. FLEMING, F.R.S.

If one junction of a thermo-electric couple is at a temperature t degrees, and if the two junctions of the couple differ in temperature by a very small interval dt, and if the electromotive force of the couple under these conditions is dE, then the *thermo-electric power* of the couple at the temperature t degrees, denoted by P, is defined by the relation $P = dE/dt$. The well-known thermo-electric diagram of Professor Tait embodies the results of his own investigations on the thermo-electric powers of metals within the limits of the temperatures which can be reached by mercury thermometers and certain temperatures above this range. Starting from the facts first made known by Lord Kelvin in his classical thermo-dynamical researches, Professor Tait showed that on certain assumptions the curves representing thermo-electric power plotted as a function of temperature should be straight lines, and consequently that the lines of thermo-electromotive force obtained by plotting as ordinates the electromotive force in a thermo-electric circuit of two metals, one junction of which is kept at a constant temperature, whilst the temperature of the other junction is varied, should be parabolas with their axes vertical if plotted in terms of the variable temperature as abscissæ. Experiment within the above-mentioned range of temperature confirmed these conjectures for a large number of thermo-couples, but led to the remarkable discovery that the thermo-electric lines of certain metals—notably of the magnetic metals, nickel and iron—are, for temperatures above zero Centigrade, broken lines characterised by sudden changes of direction. This thermo-electric diagram of Professor Tait exhibits in a very elegant manner the chief thermo-electric facts, and enables the temperature of inversion to be determined by inspection.

Having it in our power to carry down the temperature of a thermo-electric junction to values in the neighbourhood of −200°C. by the employment of considerable quantities of boiling liquid air and liquid oxygen, we have been able to conduct an extensive investigation on the thermo-electric powers of metals at temperatures lying between this low temperature and that of the boiling-point of water; and have been thus enabled to continue the thermo-electric diagram down to temperatures not very far removed from the absolute zero. We have accordingly been able to determine the points of electric inversion which lie between 0°C. and −200°C., and to compare those observed values with those predicted by the extrapolation of the existing thermo-electric diagram of Professor Tait obtained from observations at higher limits of temperature. The chief interest, however, attaching to these investigations was the ability to determine whether, over these wide limits of low temperature, the thermo-electric lines of various metals remain straight lines, and whether any of the metals exhibit changes of thermo-electric power at low temperatures which cause their thermo-electric lines to be bent or broken—thus indicating a sudden change in the sign or magnitude of the "Thomson effect" at certain temperatures. The results of these experiments have been set out in a chart of thermo-electromotive forces of the various metals and alloys used in conjunction with pure lead as a thermo-couple.

The metals used by us in this investigation were for the most part in the form of wires, and were in many cases taken from the samples of pure metals employed by us in a series of determinations of the specific electrical resistance of metals at low temperature.†

Omitting as unnecessary an account of much preliminary investigation, we proceed to describe the final experimental arrangements as follows:—A large number of thermo-electric couples were prepared, each consisting of two wires of lead joined by an intermediate wire of another metal M. The lead wire was prepared by pressing pure lead into a wire ·0656cm. in diameter, and the other metallic wires had diameters approximately from about ·025 to ·15cm., or else were used in the form of very thin narrow strips. The lead wires had a length of 50cm., and the connecting wire of the metal or alloy M a length of about 54cm. The junctions of each couple having been carefully soldered together, each wire was covered over with paraffined silk ribbon so as to insulate it, leaving only one junction exposed. A number of these thermo-couples were made up into a bundle, the sets of bare and covered junctions being bound together compactly, the bare in one group and the insulated junctions in another. In all the experiments to be

described, the set of junctions which were insulated was kept at 0°C. by being immersed in finely-crushed melting ice, kept well drained; the other set of junctions was exposed to temperatures ranging from −200°C. to +100°C. Two measurements had then to be made, viz., that of the temperature of the heated or cooled junction and also that of the electromotive force set up in the corresponding thermo-couple by the difference of temperature of the two junctions. The chief experimental difficulty encountered was that of determining the low temperature and determining it at the instant when the electromotive-force measurement of the couple was made. After long preliminary experiments necessary to overcome obstacles in the path, the successful method of dealing with the problem was found. These difficulties arose almost entirely out of the fact that for our purpose it was not sufficient to determine the thermo-electromotive force of the M-lead couple at fixed isolated temperatures, but we desired to terminate it at any of the intermediate points of temperature lying within the range of 300deg. from −200°C. to +100°C. over which we were working. The apparatus finally constructed was based upon the employment of a platinum thermometer of particular form for measuring the temperature, and a measuring instrument which could be changed instantly from a potentiometer into a resistance balance.

of copper. These half-cylinders had bevelled edges. One half-cylinder was soldered to the central tube, and the other half-cylinder was insulated from the tube and from the first half-cylinder by a slip of mica. The whole was formed into a fairly true cylinder on the outside. Two wires of platinoid No. 18 S.W.G. and 30cm. long were then soldered to the two insulated half-cylinders. These platinoid wires were kept apart by distance-pieces of ebonite. A thin sheet of mica was then wrapped round the cylinder, and over this was wound 100cm. of pure annealed silk-covered platinum wire. One end of this wire was soldered to one copper half-cylinder, and the other end to the second insulated half. It will thus be seen that we had a platinum wire connecting the ends of the platinoid wires, but wound on a highly conducting copper cylinder, the over-all diameter of the bobbin being about a centimetre and a quarter. This wire constituted the platinum thermometer which will hereafter be spoken of as the working thermometer. A section and elevation of the thermometer is given in Fig. 1. To the ends of the platinoid wires were soldered long stranded and well-insulated flexible copper connecting leads. A duplicate was then constructed in exactly the same manner, save that it had no platinum wire but had the two copper half-cylinders connected metallically together. The object of constructing this duplicate was to be able to eliminate from all measurements the

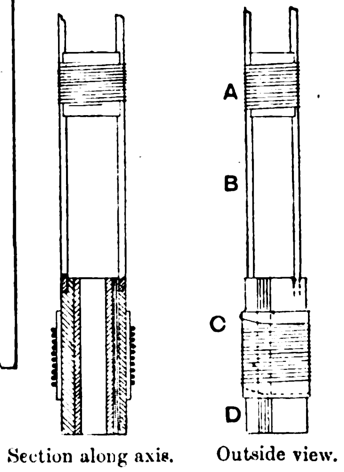

Fig. 1.—Platinum Thermometer used for Thermo-Electric experiments. A = Ebonite Distance-piece; B = Platinoid leading wires; C = 100 cms. of Platinum wire; D = Thin Mica.

In our previous researches on electric conductivity at low temperature, we fully satisfied ourselves that a wire of carefully annealed pure soft platinum can be cooled as often as necessary to the temperature of boiling liquid air or oxygen and yet return always to the same electrical resistance at a normal standard temperature. Professor Callendar has demonstrated that this quality of the constancy of resistance of pure annealed platinum at determined temperatures renders it admirably adapted for thermometric purposes; and Callendar and Griffiths have shown that a properly arranged platinum resistance affords the most suitable means for determining temperatures, and our own work at low temperatures has confirmed this fact. In our investigations on the electrical resistance of metals and alloys, we gave all our temperature-measurements in *platinum temperatures*, as defined by one standard platinum thermometer; and all the measurements in this present thermo-electric research are given in terms of the same standard platinum thermometer, which we shall hereafter mention as our standard platinum thermometer P_1. If at any time it becomes necessary, these temperatures can be reduced to other scales of measurement.

For several reasons it was necessary to construct a platinum thermometer of special form for this thermo-electric work; and this was made as follows:—A small cylinder or tube of copper 3·2cm. long, and having a longitudinal hole through it ·64cm. in diameter, was wrapped round with two other half-cylinders

resistance of the platinoid and copper wires forming the connectors of the platinum thermometer wire.

Our platinum thermometer consisted therefore of a platinum wire and of connecting conductors partly of platinoid and partly of stranded copper wire, and blank or duplicate composed of a loop of an identical platinoid and copper wire. The reason for interposing the platinoid wire was as follows. As will be seen presently, our method of procedure to obtain temperatures intermediate between fixed and known temperatures, such as that of the boiling-point of liquid oxygen and the mixture of solid carbonic acid and ether, was to embed the thermo-junctions in a mass of paraffin wax, and this mass having been cooled down to about −200deg., was allowed very slowly to heat up again. If the platinum thermometer with copper leading-in wires is immersed in this way in paraffin wax, to determine the temperature of the junctions, then, as the thermal conductivity of the copper is greatly increased by cooling it, heat will very rapidly flow into the thermometer along the leading-in wires; and it was found by preliminary experiments quite impossible under these conditions to keep the temperature of the platinum wire used as a thermometer down to the same temperature as the thermo-junction in contact with it. By employing an alloy like platinoid of a rather high specific resistance, and by making the cross-section of these platinoid leading wires relatively somewhat small, it was found possible to greatly hinder the passage of heat along the legs of the thermometer, and yet by the

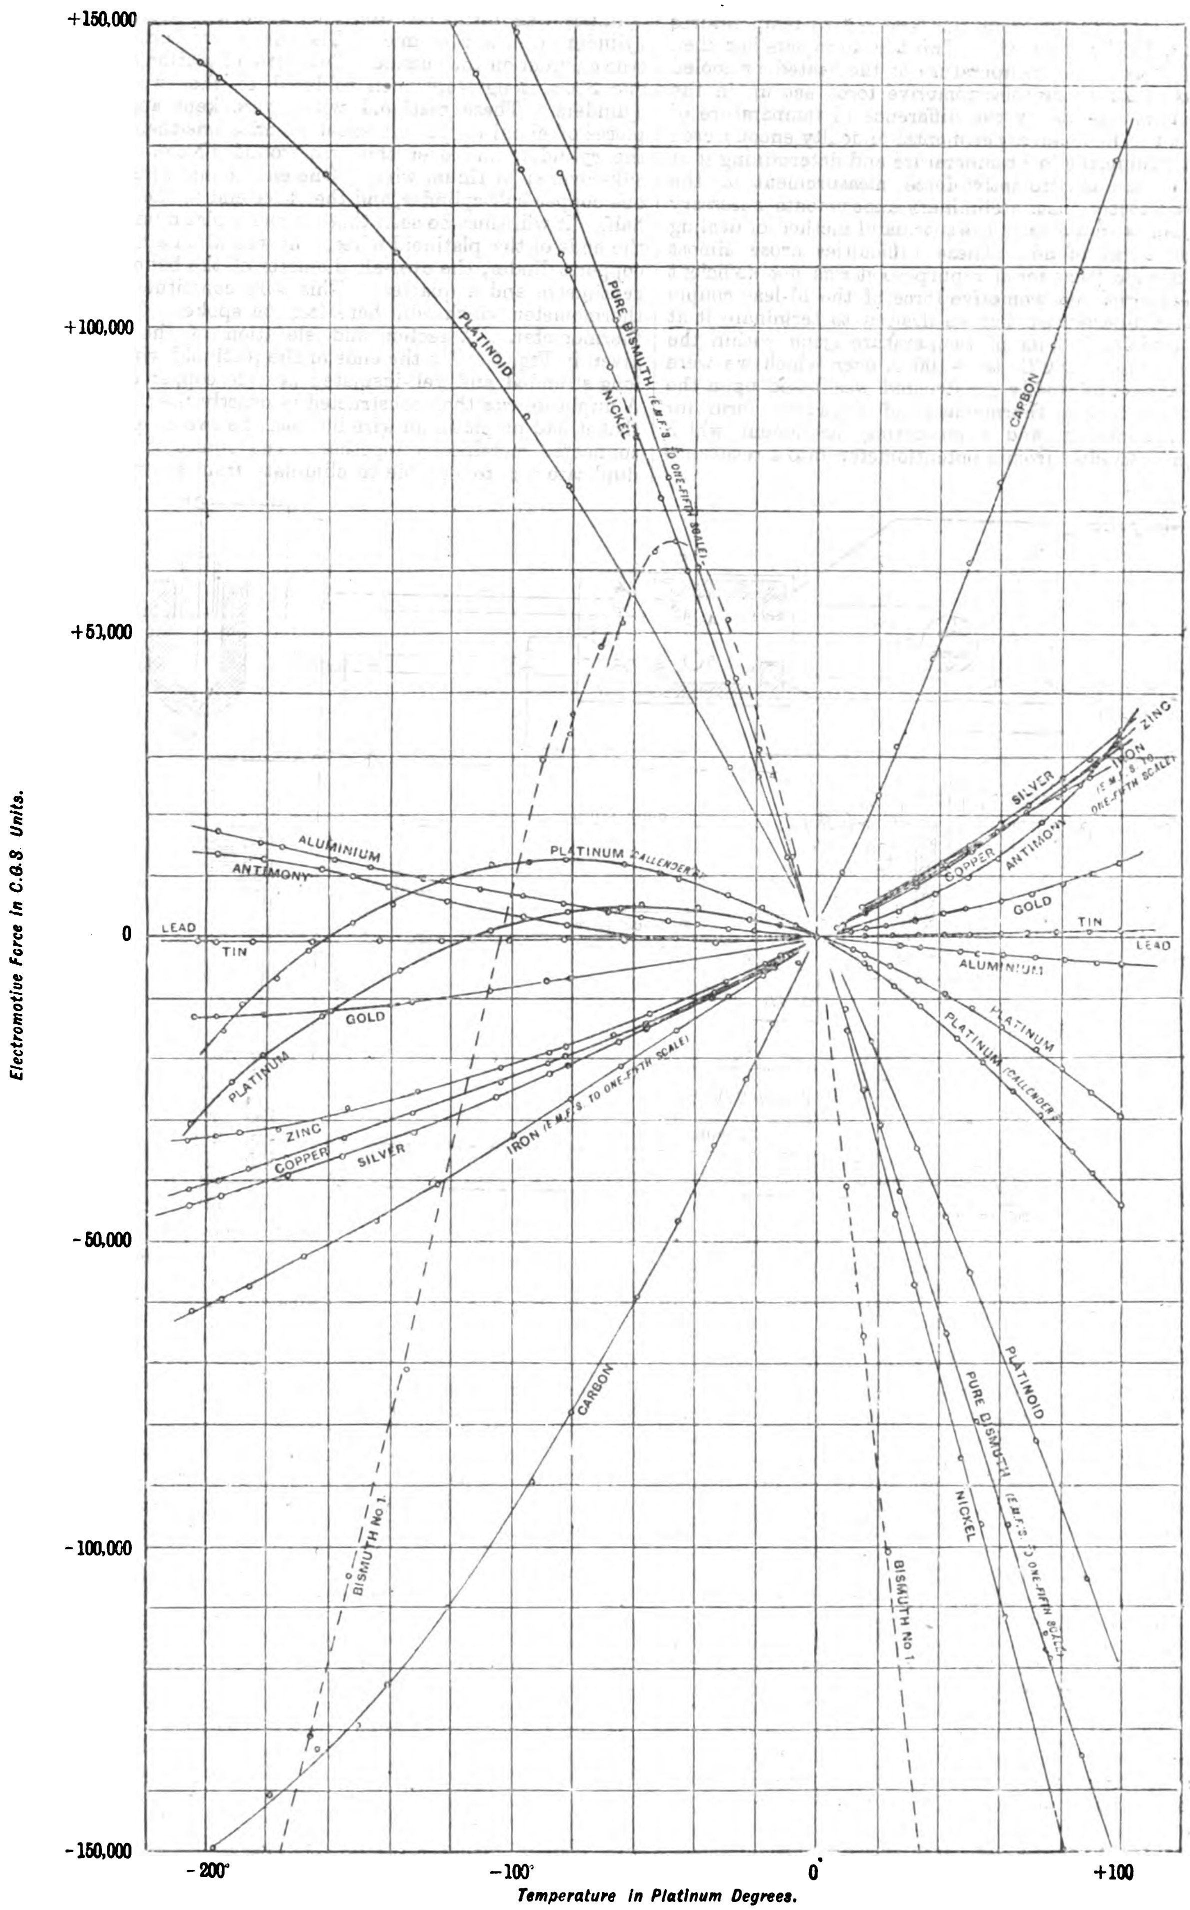

FIG. 3.—Thermo-Electromotive Force Curves of Pure Metals and Alloys

Digitized by Google

employment of an identical blank conducting circuit to determine the exact temperature of the platinum wire itself from its measured resistance.

Returning, then, to the construction of the thermometer, we may mention that it was constructed of a length of platinum wire given to one of us by Professor Callendar, and that this specimen was remarkable for its relatively large temperature coefficient. In order to determine the resistance, and therefore the temperature, of this platinum thermometer, a slide-wire bridge was constructed. A length of two metres of uniformly drawn manganin wire was stretched over a two-metre scale. This wire constituted the bridge slide wire. It had a diameter of ·0193c.m. (No. 36 S.W.G.) and a resistance at 15°C. of 26·576 ohms. It was very carefully calibrated for resistance per unit of length. Over this slide wire moved a contact-maker; and the other two arms of the bridge consisted of a coil of manganin wire wound on a small bobbin and having a resistance of 5·000 ohms at 15°C., and the above-described platinum thermometer or the resistance representing its leading-in wires. The battery employed with the bridge was a two-cell lithanode secondary battery, and the galvanometer a Holden-Pitkin suspended-coil galvanometer of 4 ohms resistance. Battery and galvanometer keys were inserted in the circuits as usual.

The first step in the investigation consisted in determining the resistance of the platinum thermometer attached to this bridge, which we shall speak of as the working thermometer P_2, at temperatures defined by our standard platinum thermometer P_1. These platinum temperatures it may be mentioned are defined as follows:—A platinum wire has its resistance determined at 0°C. and 100°C., correction being made for the resistance of its own leading-in wires. A horizontal line on a chart is then taken to represent temperature on the platinum scale and ordinates are set up at distances represented by 100 divisions on this horizontal line, and these ordinates made proportional in length to the true resistance R_0 and R_{100} of the standard platinum wire at 0°C. and 100°C. respectively. Through the summit of these ordinates a straight line is then drawn, and the point where it cuts the horizontal axis of temperature is the absolute zero of temperature by that wire. The platinum temperature of any other body, say of boiling liquid oxygen, is then obtained by measuring the resistance of the standard platinum wire immersed in this medium, and after correcting for the resistance of the leading-in wires, obtaining the true resistance R of the standard wire in the liquid oxygen. On looking out on the chart the vertical ordinate, which to the selected scale represents this resistance, it will indicate by its abscissa the platinum temperature *pt* by that thermometer of the boiling liquid oxygen. For our standard thermometer P_1 the absolute zero is −283°·0 platinum degrees on the above-described scale of temperature.

Having determined the resistance of the working platinum thermometer and of the standard platinum thermometer when immersed together in boiling liquid oxygen, solid carbonic acid and ether, melting ice (0°C.), and boiling water (100°C.), we were able to construct a curve which gave us the true platinum temperature in terms of our standard platinum thermometer P_1 of the working platinum thermometer P_2 when immersed in any medium which gave it a definite resistance, and hence a definite point of balance on the slide wire of the bridge. In order to shorten the labour of correcting the observations, a scale was constructed which enabled us to infer by inspection at once from the actual slide-wire reading the temperature of our working thermometer P_2 in terms of our standard platinum thermometer P_1, all corrections for connections being included. Hence, when the working thermometer P_2 is immersed in any liquid or region of sufficiently constant or slowly varying temperature, and when the position of balance of the contact on the slide wire is found so that the resistance bridge is balanced, then we know from this scale at once the platinum temperature of the wire of our working thermometer in terms of our standard platinum thermometer. This bridge and thermometer has proved of the very greatest use, since it enables us to measure instantly any temperatures between absolute zero and something approaching to 200°C., which is the highest our working thermometer will bear without injury. As an instance of the degree of accuracy in temperature measurement we can obtain with this instrument, we may mention that in the neighbourhood of −196°·7, which is the platinum temperature of boiling liquid oxygen, we can with ease distinguish a change of temperature of one twenty-fifth of a degree. The same degree of accuracy is not obtained at all temperatures; but the temperatures between 0°C. and 100°C. can be determined to within one-tenth of a degree with ease.

The above arrangements therefore enabled us to instantly determine the temperature of the platinum wire of our working thermometer, and therefore, when the temperature was constant or very slowly varying, to determine the temperature of the hollow copper cylinder on which the working platinum wire was wound.

The set of bare junctions of the thermo-couples prepared as described above was then inserted into the hollow interior of the little copper cylinder of the working thermometer, and kept tightly pressed against the copper by a small conical wooden peg. We satisfied ourselves by experiment that under these conditions, if the temperature of the region in which the copper cylinder was placed was constant or very slowly varying, the temperature of the platinum wire wound round the copper cylinder was the same as that of the junctions packed into the interior of the cylinder. This being the case, we had at once the means of determining the temperature of the junctions by means of one measurement, made instantly, of the resistance of the platinum wire.

We have next to describe the arrangements for determining the thermo-electromotive force set up in the couples when one set of junctions was kept at 0°C., and the other varied. This was accomplished by the employment of a potentiometer arrangement (*see* Fig. 2). The calibrated manganin wire used for the resistance balance serves also as a potentiometer wire, and the same secondary battery and galvanometer by a different arrangement of connections are employed to complete the potentiometer. A platinoid resistance of 18,200 ohms was constructed, and also a set of four coils of manganin wire of the same diameter as the bridge wire were prepared, and the whole of these coils joined in series with the bare manganin wire stretched over the scale. These four coils had resistances respectively equal to one, two, three, and four times that of the bridge slide wire. We then constructed an arrangement by which we could use the same slide wire either as a bridge to measure the resistance of the working platinum thermometer, and hence to determine the temperature of the junctions inside it, or to measure the electromotive force set up in the thermo-couple by balancing it against a variable standard potential difference calibrated with reference to a Clark cell.

It was necessary to make provision for changing the bridge into a potentiometer very rapidly, and for the purpose the connections of the different parts of the apparatus were arranged as shown in Fig. 2, so that by one movement of a double copper connecting-piece the connections of the apparatus could be instantly changed from a bridge to measure the temperature of the thermometer, to a potentiometer to measure the electromotive force of the thermocouple. The whole of the electromotive-force measurements are therefore referred to a Clark cell. The arrangement of the combined bridge and potentiometer may be described a little more in detail as follows, and will be easily understood by reference to the diagram (Fig. 2).

The operations of measurement were then as follows:—One set of the thermo-junctions being immersed in melting ice, the working thermometer, with the other set of thermo-junctions packed inside it, was placed in a small copper tube closed at the bottom end, not touching the tube, and this was filled full of melted paraffin wax. The copper tube was then placed in a test tube and the whole filled with melted paraffin wax, to between the copper tube and the glass test tube. When the wax was solid, the mass containing the thermometer wire and junctions enclosed within it was cooled down by the employment of considerable quantities of liquid air to a temperature of about −200deg. As soon as the temperature had become constant, the mass of paraffin was lifted out and placed in a vacuum-jacketed vessel that it might become heated up by conduction and radiation very slowly. A series of observations was then taken for each junction in rotation, measuring first the temperature of the junctions by the thermometer-wire resistance, then changing the connections, and measuring the electromotive force of the couple, then changing back again to the bridge arrangement to get the temperature of the junction again; and so on for each couple in rotation, as the mass of paraffin slowly warmed up. In this manner a series of observations was obtained which, when reduced, gave the electromotive force of the couple in absolute C.G.S. units and the standard platinum temperature (*pt*) of the variable junction at that instant, the other junction being kept at 0°C. all the time.

By the employment of carbonic acid and ether and a paraffin-oil bath the series of observations for closely adjacent temperatures was continued for each thermo-couple from the boiling-point of liquid air up to the boiling-point of water. In addition to this, very careful observations were taken of the E.M.F. of all the couples at fixed stationary temperatures, such as that of the boiling-point of liquid oxygen, the melting-point of solid carbonic acid, the melting-point of ice, and the boiling-point of pure water, and the intermediate observations were made in some cases with the temperature of the junctions rising, and in some cases falling, to give assurance that the temperature of the platinum wire was the same as that of the junctions, and did not lag behind it. Satisfactory evidence was obtained that the temperature of the platinum wire did truly represent the temperature of the thermo-junction buried in the interior of the thermometer.

We were thus enabled to obtain a series of numbers for each metal, representing at defined temperatures the thermo-electromotive force of that metal against lead. Having still in our possession a small quantity of exceedingly pure lead prepared in M. Stas's laboratory which was kindly given to us by Mr. George Matthey for our previous resistance experiments, we were enabled

Digitized by Google

to measure the thermo-electromotive force of a couple formed of this pure Stas's lead and the ordinary lead used by us as the associated metal for all the couples. It was thus possible to reduce all our observations of thermo-electromotive force to a statement of the electromotive force in C.G.S. units of a couple formed of a metal M and of chemically pure lead, one junction being at 0°C., and the other being at a platinum temperature *pt* as defined by our standard platinum thermometer P_1. The results of some of the corrected observations are graphically shown plotted down in the chart (Fig. 3).*

These lines of thermo-electromotive force thus found in terms of platinum temperature are in all cases curved lines. Wherever the curve has a maximum point so that its tangent becomes parallel to the line taken as the axis of temperature, the temperature at which this occurs is the neutral point of that metal or alloy with regard to lead. If at any temperature the tangents of the curves of two metals are parallel to one another, that temperature is the neutral point of those two metals with regard to each other, or is the temperature of inversion. The diagram of thermo-electric powers can be at once obtained from that of the thermo-electromotive forces by drawing a series of lines, the ordinates of which represent to a proper scale the *slope* of the curves or thermo-electromotive force.

With regard to the purity of the metals employed in this research, we may mention that the samples of platinum, gold, silver, palladium, copper, tin, lead, cadmium, magnesium, nickel, (Mr. Mond's nickel deposited from nickel carbonyl), zinc, and aluminium were either the same wires as were used by us in our investigation on specific resistance, or were of equal purity. The antimony and bismuth were prepared for us by Mr. George Matthey, to whom our thanks are especially due for valuable assistance in this matter. The other alloys used were taken as found in commerce. The iron was a sample of the softest annealed transformer iron obtainable. As regards the manganese steel, two samples of Hadfield's 12 per cent. manganese steel were used, one in its ordinary non-magnetic cóndition, and one of the same composition but which had been rendered sensibly magnetic by heating it to a full red-heat. It will be seen that this operation quite appreciably alters its thermo-electric value. The carbon used was a carbon filament from an incandescent lamp.

We propose to reserve for a future communication a full discussion of the interpretation of these curves and the bearing of the facts they disclose on the usually accepted thermo-electric theory. Meanwhile it may be sufficient to note that none of these thermo-electric curves are true parabolas over their whole extent. Many of the curves as drawn in the chart are curves of double curvature, and in some cases point to the existence of more than one neutral point with lead. We propose to convert this chart of electromotive forces into a chart of thermo-electric powers, in which last condition it will lend itself better to a discussion of results.

A few remarks may, however, be made respecting the thermo-electromotive force curves shown in the chart. The lines of iron and pianoforte steel, as well as some others, have changes of curvature at certain points which indicate that the thermo-electric lines are broken lines. The line of antimony has two points at which its tangent becomes parallel to the line of lead, indicating that the thermo-electric line of antimony cuts that of lead twice. The bismuth lines are very peculiar. The curves marked Bismuth No. 1 and Bismuth No. 2 are specimens of impure or commercial bismuth; but both these and the curve of pure bismuth have a sudden break or discontinuity in their course at about −80deg., which we think is not due to errors of experiment. These and many other points are receiving consideration, and will be discussed in a subsequent communication.

We must, in conclusion, express our great obligations to Mr. D. K. Morris, as well as to Mr. C. Jakeman, for the valuable assistance they have rendered to us in the laborious work of taking and reducing the observations above recorded, as well as in the construction of some of the apparatus used in this research.

* In the full Paper all the results are plotted and are also given in tables.

LONDON COUNTY COUNCIL.

THE ELECTRIC LIGHTING OF THE THAMES EMBANKMENT AND BRIDGES.

At the weekly meeting of the London County Council, held at the County Hall on Tuesday, Sir Arthur Arnold presiding, the Highways Committee reported having last year submitted to the Council a scheme for the electric lighting of the Victoria Embankment and Gardens and Westminster and Waterloo Bridges, for which purpose the Council obtained powers in its General Powers Act of 1893, and £15,000 was provided in the Money Act of that year. The scheme which they then proposed would have involved a capital expenditure of £20,000, and an annual expenditure for maintenance and interest and redemption of loan of £3,880. On that occasion the Council adjourned the question till the spring of the present year. The Committee had since reconsidered the scheme with a view to reduce not only the expenditure on capital account, but also the cost of maintenance, and having regard to the fact that the Embankment Gardens only required lighting for a short period of the year, in the new scheme they had made no provision for lighting them. In the revised scheme which they now proposed duplicate plant was provided for either set of plant, being capable of lighting the Embankment and the bridges; the generating station was of fireproof construction, so securing the maximum of safety; whilst the cost of the buildings had been reduced by the omission of ornamentation, leaving them as efficient as before. The electric lamp standards would be placed on the kerb on each side of the footways, leaving the parapet lamps to be lighted when required by gas as at present, and the existing lamp standards on the two bridges would be provided with the electric light. It was proposed to provide 83 lamps in all. Should the Council decide to adopt the scheme they proposed to ask the Technical Education Board to allow its inspectors of art schools and classes to assist them in preparing designs for the lamp standards, and they hoped to be able to obtain a design for a standard of lamp which would be worthy of being placed in that, the first thoroughfare in London. The capital cost of the scheme was estimated at £16,590, made up of the following items:—Buildings, £4,600; boilers and machinery, £5,200; mains, £2,250; lamps and standards, £4,240; salaries, £300; of which about £3,000 was included in respect of the two bridges. The estimated annual cost of maintenance was £2,768. In making the estimates it had been assumed that the repayment of the loan would be spread over 42 years, which was the period for which the Council was now granting loans to vestries for electric lighting purposes. They recommended "That, subject to an estimate being submitted to the Council by the Finance Committee, as required by the statute, the Highways Committee be authorised to take all the necessary measures for establishing at a cost not exceeding £16,590 electric lighting for the Victoria Embankment and the Waterloo and Westminster Bridges (but exclusive of the Embankment Gardens) authorised by the Council's (General Powers) Act, 1893; and that for this purpose the Committee be authorised to obtain tenders and to enter into contracts on behalf of the Council.

As the recommendation deals with a capital expenditure of over £5,000 the matter, in accordance with the standing orders of the Council, was adjourned for a week.

THE FIRE AT THE SARDINIA STREET STATION.

The Highways Committee of the London County Council on Tuesday reported to the Council that they had received notice from the Metropolitan Electric Supply Company with plans to lay mains in Little and Great Wild-streets, Kemble-street, Russell-street, Wellington-street, Exeter-street, and part of the Strand, the work being necessitated by the recent fire at the Company's generating station in Sardinia-street. They recommended that the plans be passed on condition that the works in the Strand, when commenced, shall be carried on continuously both by day and by night until completed; that the mains be inclosed in iron pipes or efficient casing, and be laid under the footways wherever it is found practicable to do so; that drawings of the proposed street boxes, showing adequate means for ventilating them and also showing the exact positions in which they are to be placed, be submitted to and approved by the Council's chief engineer before the work is commenced; that as an additional precaution against accident through defective insulation of the mains, each of the street boxes be provided with an inner as well as an outer cover, the two insulated from each other as far as practicable, and that the outer cover, which shall consist of an iron frame filled in with material to suit the paving, shall be efficiently connected to earth.—The recommendation was agreed to.

CORRESPONDENCE.

SHIPBOARD GALVANOMETERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to Mr. Wilkinson: With regard to my galvanometer, as described in *The Electrician* of March 22nd last, might I state that, in comparing electrostatic throws, the damping device is not required, the instrument being, in itself, sufficiently dead-beat and slow of movement to allow of such observations being made with facility and exactitude. The camel's hair brush, or as I may be permitted to term it, the *extra* damping device, is mainly useful in cases where absolute deadbeatness, together with reduced sensibility, are desirable; (as, for example, in mirror speaking through very short and practically non-inductive lengths of cable), and therefore it is so arranged that it can be instantaneously applied or withdrawn from action at will.

In the latter case, this form of galvanometer combines with great deadbeatness an entire freedom from shifting of zero or creeping, and what is alike indispensable in an instrument of precision, the deflections are proportional to the current.

Any mechanical damper must, of necessity, introduce in greater or less degree creeping or zero trouble, besides want of proportionality between current and deflection; hence the convenience of the brush damping arrangement, which can be immediately applied or withdrawn from use, as occasion may require.

The other general and marked advantages of this type—namely, its independence of external magnetic disturbances such as changes in the ship's course, &c; the facility with which it can be balanced for rolling; its deadbeatness, simplicity and portability—were pointed out in your article.

The figure of merit of the instrument as suspended for sea use now well exceeds that of the ordinary "Thomson Marine," wound to 6,000 (ohms), and I may add that the simplicity and success of its balancing device has been fully proved on an important cable-laying expedition for which this form was adopted.—Yours, &c.,

29, Ladbroke-square, W., H. W. SULLIVAN.
July 8, 1895.

WAVE FORM SYNTHESIS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Prof. Ayrton has kindly called my attention to an oversight in the diagram (Fig. 1) in my letter in *The Electrician* of July 5th.

Rheostats R_1 R_2 R_3 are shown in series with the three circuits of the elemental armatures, but, of course, there should be resistances *in shunt* across terminals t_1, t_2, t_3 t_4, and t_5 t_6 respectively.—Yours, &c., JAMES MARK BARR.

THE THWAITE-CAWLEY CONDUIT SYSTEM.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the leading article of your issue of last week you have been kind enough to refer to a Paper read by me before the Tramways Institute, in which I attempted to give an outline description of a new electric traction system intended for urban tramways, and I should be obliged if you would afford me space for a few words in the way of reply.

You state that my Paper "was received with some distrust." Granting, for ease of argument, that such was the case, I am inclined to think that a spirit of distrust is a commendable one for receiving any suggested innovation in the first instance. It would have been a good thing for many investors if this spirit had been more general a few years ago, when company promoters were enjoying a decidedly rosy time. No inventor can reasonably complain at having his claims received at first in a qualified manner. It is generally understood that he is in the position of a special pleader, whose business it is to extol the merits of his invention. But he may ask, and with reason, that any claims he may put forward should be criticised from an impartial standpoint, and with a full knowledge of the details upon which his claims are based. As regards my Paper, I endeavoured to make it entitled to this method of criticism by dealing as impartially as I could with present methods of electric traction in respect of their fitness for meeting the requirements of British tramway enterprise.

Now, with regard to the measure of "distrust" with which you state my Paper was received, permit me to point out that not a single objection was made to the conduit system I described by anyone directly connected with tramway management. The discussion was mainly carried on by two gentlemen of well-known engineering reputation, but I am not quite sure that their connection with rival systems is so remote as to include them within the category of impartial critics. There is an excellent rule observed in our courts of law in pursuance of which a judge is expected *not* to hear cases where his personal interests might be considered to bias his judgment. If such a rule be thought advisable in order to give weight and credit to the judgments of men eminently fitted by training and natural bent of mind to reason fairly, it seems even more necessary in the case of laymen, and had it been rigidly observed by the critics of the system I described it is not improbable that their *rôle* would have been one of silence.

However, as they decided to speak, it is a pity they had not taken the trouble to study the details of the proposed scheme. They probably thought that a few random shots would suffice to vanquish this youngest appellant for tramway favour. But the lack of precision in attack left the reply on my part an easy task. For instance, one speaker doubted whether motors of the power stated could be carried with eight-inch driving wheels, and the remark would be true with motors as usually applied under the cars; but in the culvert of this system there would be no difficulty in putting motors of double the stated power on eight-inch wheels, as the culvert rails can stand any required height above the base of the culvert. The same speaker then ridiculed the idea of obtaining the required tractive effect between the driving wheels and the rails by any other means than that of simple weight upon the wheels, as in the case of a railway locomotive. He had failed to observe that the method adopted for automatically increasing the pressure upon the driving wheels, in accordance with the tractive force required, permitted a gradient of any steepness to be mounted, while the ordinary electric tramcar is confined to a limited gradient. In this respect the proposed system possesses all the advantages of cable traction, or of the grip-rail system as used on mountain railways. In short, it may be looked upon as the cable tramway system in electrical dress.

So much for the value of the criticisms directly affecting the scheme described by my Paper. Although the scheme was only indifferently presented to the meeting in an outline and suggestive form, I think that I may fairly claim that the discussion, so far as it went, did not materially affect a single claim made on behalf of the system.

Another part of the discussion was directed against accepting Papers relating to schemes which have not been practically carried out; but as I was officially invited to read my Paper, any remarks under this head do not directly concern me. The point raised is entirely one of policy, and each Institution must decide this for itself. No doubt the astute and able President of the Tramways Institute is quite capable of adopting the policy which will best serve tramway enterprise in this country, and I do not think it will be one less liberal than that followed by similar institutions in close touch with our industrial life which do not think it "mere waste of time" to discuss proposals which have not yet reached the fulness of maturity. What of the Bessemer method of making steel, cited by me in the discussion—one of the most important and far-reaching inventions the world has yet seen? Was the discussion on this deferred till the process was matured? Of course not; and the same is true of a number of inventions and schemes now of great public advantage.—Yours, &c., GEO. CAWLEY.

29, Great George-street, Westminster, S.W.,
July 10, 1895.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

SPECIAL NOTICE.—The 1895 (thirteenth) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. In addition to the old well-known features of the book, which are brought up to date, a quantity of new and useful matter has been added, rendering the book more than ever indispensable to the Electrical, Engineering, and Allied Trades. Price, 7s. 6d., post free 8s. 3d., abroad 9s.

The following New Books and Editions of "THE ELECTRICIAN" SERIES *can be obtained of the Booksellers or direct from the Publishing Offices* :—

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio price 12s. nett, or bound in strong cloth case price 12s. 6d. nett (*now ready*). Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

A LARGE-SHEET TABLE, giving full particulars of the Electricity Supply Stations throughout the Kingdom, can now be supplied mounted on stout board, with cord for hanging. Price: Varnished, 3s. 6d.; Unvarnished, 3s.—each post free. A Map showing positions of Supply Stations throughout the country is mounted on the back of the Table, and a Coloured Map of Metropolitan Electric Lighting Areas and a large sheet of Electricity Supply Statistics are also mounted on some copies, the price of which complete, post free, is 5s.

A SHEET TABLE showing Total Capital Outlay and Receipts and Expenditure for the year 1894 of the Statutory Electric Supply Undertakings of the Metropolis is now ready, printed on thick paper, price 6d. each.

TENDERS INVITED.—The Brighton Borough Council invite tenders for the supply and erection of steam and feed piping, cast-iron storage tanks, feed water filters, electrically-driven feed pumps, circulation economiser, coal elevator and sundries. Also and erection of evaporative brass-tube surface condensers, electrically-driven air pumps, exhaust and condenser piping. Tenders must be in by 10 a.m. on Monday next.

——— From our advertisement columns it will be seen that the Metropolitan Asylums Board require tenders for the supply and running of mains in the grounds, and for the wiring of buildings now being erected at the North-Western Fever Hospital, Haverstock Hill, N.W. Copies of the conditions and specifications may be obtained at the offices of the Board, Norfolk House, Norfolk-street, London, W.C., and tenders must be sent in by 11 o'clock on Thursday next, the 18th inst.

——— The Urban District Council of Wellington (Salop) invite tenders for lighting the district by electricity or gas. Tenders before noon on Monday next, July 15th.

——— The Crown Agents for the Colonies require tenders, to be delivered by 11 a.m. on Thursday, August 1st, for the supply of materials in connection with the installation of the electric light in the Civil and War Department buildings at Malta. The materials required comprise cables and wires, tools, &c., fittings, fixtures, &c., and sundries.

——— Tenders are invited by the Vestry of Hammersmith, London, W., for complete schemes for public and private lighting, and for the supply of motor power in the compulsory area of the Vestry's Provisional Order. Further particulars can be obtained of Mr. H. Moir, Surveyor to the Vestry, and tenders have to be sent in by 6:30 p.m. of Wednesday, September 4th.

——— The Barker's Bridge House Trust, Datchet (Berks.) require tenders for lighting the village of Datchet, from October to March, with electricity, oil or gas. Tenders, addressed to the Trustees, care of Mr. H. L. Prior, the Priory, Datchet, must be in by the 20th inst.

TENDERS ACCEPTED.—The Birkenhead Town Council have now accepted the tender of Mr. John Shaw (a local firm), for erecting the electricity generating station in Bentinck-street for the sum of £4,900. It will be remembered that the contract was originally awarded to Messrs. Holme and Green, of Liverpool, but owing to an error that firm asked leave to amend their tender, but this the Council refused.

TENDERS ACCEPTED.—The Hanley Town Council have accepted the tender of Messrs. Crompton and Co. (Limited) for 30 arc lamps and 29 cast-iron pillars for £539.

——— The Portsmouth Corporation have received the following tenders for the supply of conduits and electric mains for lighting the Infectious Diseases Hospital at Milton :—

	£	s.	d.
J. Southey, Southsea	£211	0	0
Walker and Co., Portsea	202	12	6
Bowerman Bros., Southsea	208	10	6
Sotheby and Co., London	188	10	0
W. H. Sabine, Southsea (accepted)	152	0	0

——— The Taunton Town Council have accepted the tender of Mr. F. M. Newton (a local firm), for the supply of a main switchboard for the electricity works.

APPOINTMENT VACANT.—The Bradford Corporation are prepared to receive applications for the appointment of engineer to take charge of their electricity works at a commencing salary of £300 per annum. Applications must be sent in to Mr. W. T. McGowen, Town Clerk, Town Hall, Bradford, by the 17th inst. Some further particulars are given in our advertisement columns.

——— The Governors of the Northern Polytechnic invite applications for the post of principal. After the 25th March next the stipend will be at the rate of £500 per annum, and from September 29th next to March 25th at the rate of £300 per annum. Applications must be sent in to Mr. E. Griffiths, secretary, St. Mary's Vestry Hall, Islington, N., by Monday next.

——— The Governing Body of the Northampton Institute, Clerkenwell, E.C., are prepared to receive applications for the appointment of a principal. The salary attached to the office has been fixed at £600 per annum, and the duties will commence on January 1st next. Applications must be sent in, before 10 a.m. on September 4th, to the Clerk (*pro tem.*), Mr. J. J. Lambert, 8, Dowgate-hill, Cannon-street, London, E.C. Some further particulars appear in our advertisement columns.

DISSOLUTION OF PARTNERSHIP.—Messrs. John Bilbie and Tinsley Waterhouse, carrying on business at 80, Queen Victoria-street, E.C., as engineers, have dissolved partnership.

CAUTION.—Persons are cautioned by an advertisement elsewhere against negotiating or otherwise dealing with any parties claiming to have authority to treat for the sale of the Chaplin Vacuum Pump, French Patent No. 239,302 (1894). Messrs. Templer, Down and Miller, 3, Pope's Head-alley, London, E.C., are solicitors for the patentee.

BANKRUPTCY.—In the case of the failure of E. A. Berry, electrician, of Burnley, notwithstanding the order of the Court calling upon the debtor to file accounts from December 1st up to the date of the receiving order, no such accounts have been filed, and at the Bankruptcy Court, Burnley, last week, a further adjournment took place till August 1st, the debtor being ordered to file particulars within seven days.

"THE ENGINEERING MAGAZINE."—A special railroad number of this magazine is issued for July, and is now ready. The magazine opens with a set of handsome plates showing famous views on the American railroads, produced in a style familiar to readers of the magazine, the contents including articles on "First Principles in Railroad Management," "The Legislative Regulation of Railroads," "Reforms in Railroad Management," "Will Trunk Lines be Operated by Electricity?" (by Frank J. Sprague), "The Architecture of Railroad Stations, with Views of the Principal Railway Termini of England, France, Italy, Germany, Holland, Switzerland, and Belgium." Other articles deal with "The Financial Aspect of the Railroad Industries," "The Car Building Industry of the United States," "The Modern Railroad Machine Shop," "A Review of Railroad Invention," "The Causes of Railway Accidents," and the usual exhaustive Review of the Industrial Press. For railway men the July issue of the *Engineering Magazine* is indispensable.

DIRECTORIES.—It is not unusual for persons obtaining Governmental or Departmental sanction or assistance in the preparation of lists of names and addresses to claim either some special degree of accuracy or a monopoly in the compilation of such names and addresses. It is satisfactory, therefore, to find that Messrs. Kelly and Co., the proprietors of the well-known "Post Office London Directory," and who can fairly lay claim to the credit of compiling what has for many years proved to be the most accurate list of names and addresses ever produced, have proved successful in an action for damages for libel, and have also obtained an injunction restraining the proprietor of a directory of registered telegraphic addresses from publishing similar libels. Those responsible for the compilation of directories, and especially those who devote time and intelligence to the work in order that accuracy may be secured, are well aware that existing lists are only more or less complete, and that in order to secure perfect accuracy it is necessary that considerable individual effort should be made.

Digitized by Google

ACTON.—At the last meeting of the District Council a letter was read from the Capital and Counties Electricity Supply Company, notifying their intention of applying to the Board of Trade for an electric lighting Provisional Order. It was stated that the Council would oppose the application.

ALDERLEY EDGE (MANCHESTER).—The Altrincham and Bowdon Electric Lighting Company have notified the District Council of their intention to apply for a Provisional Order to enable them to supply electricity to the district. The discussion on the matter was adjourned to the next meeting of the Council.

ASHFORD.—The Guildford Electric Supply Company (Limited) notify the District Council of their intention to apply for a Provisional Order to enable them to light the district electrically, but the Council have decided to oppose the application. Much dissatisfaction is expressed at the present system of gas lighting, and a committee has been appointed to consider the lighting question generally.

ASYLUM LIGHTING.—At the last meeting of the Governors of the Belfast District Lunatic Asylum, a further report on the electric lighting of the new Purdysburn Asylum was under consideration. An estimate obtained in February last put the initial outlay at £1,800, and the annual cost of working, &c., at £250. The report states that as it is now contemplated to use steam power in the laundry and for various other domestic purposes, and as 10 per cent. extra would provide sufficient power to drive the lighting plant, the Committee thought it would be better to adopt the electric light, and they asked the Board to reconsider the question. After a lengthy discussion it was decided to refer the matter back to the Committee for further consideration and to have a proper specification prepared, upon which tenders will be invited.

BARNET (HERTS.).—At the last meeting of the District Council the Clerk reported that the Board of Trade would extend the time for complying with the provisions of their Provisional Order provided the Board were satisfied that the Council were doing something in the matter. At the same meeting a motion for the appointment of a special committee to consider the lighting and water supply questions, and to report thereon to the Council once a quarter, was defeated by 5 votes to 4.

BUENOS AYRES.—The *Financial News* states that the signature of the Provincial Government of Buenos Ayres has been appended to the purchase deed of the electric light installation for the city. The price paid is $239,230.50 gold, which is to be paid off by the Government at the rate of 5 per cent. per annum for the first five years, and 10 per cent. for each succeeding year till the entire amount is cancelled.

BRIGHTON.—The Town Council have now obtained the formal sanction of the Local Government Board for borrowing the further sum of £43,650 for electric lighting extensions, &c.

CARDIFF.—Last week Col. Ducat, R.E., held an inquiry into the application of the Corporation for sanction to borrow £16,000 for various local improvements, including £1,270 for lighting the Town Hall and Market by electricity.

CHAPEL LIGHTING.—Brunswick Chapel (Burnley) is now lighted electrically. The work has been carried out to the specification of Mr. S. V. Clirehugh by Messrs. Fletcher, Hirst and Co., of Blackburn.

CORK.—In our last issue we announced that the Cork Electric Light and Power Company had notified the City Council of their intention to apply for a Provisional Order to enable them to supply electric current for public and private purposes within the city. Similar notices have now been given on behalf of the local gas company and the Electricity Supply Company for Ireland (Limited).

COMMISSION OF SEWERS (LONDON, E.C.).—At the last meeting of the Commission it was decided to refund the three sums of £1,000 each deposited by the City of London Electric Lighting Company as security for the due fulfilment of the contracts entered into for lighting the City by electricity, together with the interest that had accrued thereupon, all the conditions of the contract having been complied with by the Company to the satisfaction of the Streets Committee.

COMPTON GIFFORD.—The Brush Provincial Company have notified the District Council of their intention to apply for a Provisional Order authorising them to supply electric current within this district.

COWES (ISLE OF WIGHT).—Mr. F. H. Medhurst, the expert appointed to examine the report of the surveyor to the West Cowes Council on the lighting of the district by electricity, has submitted his report, and it was presented to the Council at their last meeting. Mr. Medhurst is of opinion that sufficient expenditure has not been allowed for as to site and buildings. A suitable installation might be put down for a sum not exceeding £8,500, and points to the success of Portsmouth, Bedford, Cambridge, Taunton and other provincial towns. It will not be advisable to charge more than 6d. per unit for the current, and at that rate the electric light will be much cheaper than gas at Cowes. The revenue is estimated at £1,350 for 3,000 lights. There would be a minimum probable profit of £100 per annum as soon as the plant was fully loaded with its 3,000 lights, and the lighting in the streets would be many times more effective than at present.

DEVONPORT.—The Brush Provincial Company have notified the Town Council of their intention to apply for a Provisional Order to enable them to supply Devonport and Stonehouse with electric current. The Council have decided to oppose the application.

DOUGLAS (ISLE OF MAN).—An application to authorise the acquisition of land required for the purposes of an electric railway to the summit of Snaefell, the highest Manx mountain, came before the Manx Legislature this week.

EAST GRINSTEAD.—An attempt is being made to ascertain the views of the ratepayers in regard to the introduction of the electric light into the town, and should there be sufficient support forthcoming a company will be formed for lighting the district electrically. The consulting engineers for the undertaking will be Messrs. Owen Lucas and Pyke, of Victoria-street, London, S.W.

EDINBURGH.—The Town Council have decided to light the Waverley Market electrically at an estimated cost of £650. The Council also decided to adopt an improved system of ventilation for the Market. Rotary fans, propelled by electricity, are to be installed at a cost of about £500.

ELECTRIC CONSTRUCTION COMPANY (LIMITED).—It is stated that this Company have intimated to their employés their intention of paying them a bonus of 6d. in the £. This will be distributed during the month, and it is understood the Directors of the Company have under consideration a further scheme for giving their employés a direct financial interest in the success of the firm.

ELECTRIC LIGHTING OF TRAMWAY CARS.—At the half-yearly meeting of the London Tramways Company, on Tuesday last, the Chairman (Mr. D. P. Sellar) said that those who travelled on their cars would have noticed that many cars were now lighted by electricity. By next winter they hoped that in many more cars oil lamps would be dispensed with, and the electric light be introduced. They had to spend money to make those who used their cars as comfortable as they could, and in that way to induce them to use the accommodation which they afforded. In winter all the cars were heated, and now many of them were so well lighted that a newspaper could be read without straining the eyesight.

ELECTRIC TRACTION IN NEW YORK.—Notwithstanding the very heavy cost of the conversion to electric motive power on the New York elevated railroads, a great saving will ultimately result. It is stated that many of the railroads in the Eastern States are running freight trains with electric motors capable of drawing 450 tons at the rate of about 25 miles an hour, and passenger trains from 45 to 80 miles an hour.

FIFE.—At a meeting of the County Board on Tuesday, Mr. Haig, convener of the Sub-Committee on Telephones, stated that he had interviewed Lord Balfour as to the rent for telephone poles and wires throughout the county. The Committee had formerly agreed to demand 2s. 6d. per mile, and if the Company refused to pay this, to cut the wires. It had turned out, however, that the trunk lines of the telephone had been taken over by the Post Office, and the Postmaster-General refused to pay anything in the shape of rent. They were legally advised that they would run themselves into danger of litigation if they were to cut the wires, though he was not of that opinion himself. The fact was that Lord Balfour had the advantage of them in that he knew what was going on between the Company and the Post Office, and he had been putting them off till a convenient time.

GREAT CROSBY (LIVERPOOL).—At the last meeting of the District Council letters were received from two electric lighting companies giving notice of their intention to apply for Provisional Orders authorising them to supply electric current within the district.

HAMPSTEAD (LONDON, N.W.).—At the last meeting of the Vestry the recommendation of the Lighting Committee that further extensions of the electric lighting mains be effected at an estimated cost of about £360 was agreed to.

ILFRACOMBE.—The electric lighting question was discussed at the meeting of the Town Council last week, and it was stated that notice had been served of the intention of a private company to apply for a Provisional Order for lighting the district electrically. A special meeting has been called to consider the advisability of the Council applying for a Provisional Order, the advantages of the electric light being forcibly advocated by several members.

LEWISHAM (LONDON, S.E.)—At the last meeting of the District Board of Works a letter was received from the Capital and Counties Electric Supply Company notifying their intention to apply for a Provisional Order to supply electric current in the area of the Board's jurisdiction.

LONDON, E.C.—The extensive book room of the Primitive Methodist New Connexion, recently erected in Aldersgate-street, London, has been fitted throughout for the electric light by Messrs.

Digitized by Google

J. H. Pickup and Co. (Limited), who have, in addition, fitted an electro-mechanical system of ventilation which has proved very effective.

The Ministry.—Amongst the members of Lord Salisbury's Government are several names well known in connection with the electrical industries. Lord Balfour of Burleigh, who is Vice-President of the National Telephone Company, has been appointed Secretary for Scotland, with a seat in the Cabinet; Mr. G. W. Balfour, the Chief Secretary for Ireland, is a Director of the St. James' and Pall Mall Electric Light Company, the West India and Panama Telegraph Company, and the Aluminium Company; the Hon. W. St. John F. Brodrick, the Financial Secretary of the War Department, is a Director of the African Direct, the Brazilian Submarine, and the Globe Telegraph and Trust Companies.

Monmouth.—Col. W. M. Ducat, R.E., last week held a Local Government Board inquiry at the Shire Hall into the application of the Corporation for sanction to borrow £19,000 for the purposes of carrying out a combined sewage disposal and electric lighting scheme. Mr. Ram, who gave particulars of the scheme on behalf of the Corporation, stated that the necessary motive power would be derived from the water of the river Monnow. A petition, signed by 100 ratepayers (principally shareholders in the local gas company), was presented against the electric lighting part of the undertaking. The engineers for the scheme are Messrs. Bramwell and Harris and Mr. C. N. Lailey.

Newport (Mon.).—Last week Col. W. M. Ducat, R.E., held a Local Government Board inquiry into the application of the Town Council for sanction to borrow, amongst other sums, £1,725 for wiring and fitting the Town Hall, Corporation Baths, the Provision Market, Free Library and School of Art for the electric light.

Ossett.—The Town Council at their last meeting decided to apply for an electric lighting Provisional Order. It was explained by Mr. Audsley, who brought the matter forward, that the obtaining of electric lighting powers was intended to safeguard the rights of the Corporation, as notice had been received from an electric lighting company that they intended to apply for an Order.

Plymouth.—The City Council, at their last meeting, had under consideration the report of the Technical Instruction Committee, which announced that during the year a new feature had been introduced into the schools by the fitting up of an electrical and mechanical engineering shop, which they hoped would have the effect of advancing technical education in the town. The report was approved.

Queenstown.—Owing to the non-success of the efforts of the Town Commissioners to make satisfactory arrangements with the local gas company as to the public lighting of the town, the proposal that an effort should be made to light the district electrically has received the approval of the Commissioners, although one further attempt is to be made to arrive at a satisfactory understanding with the gas company.

St. Pancras (London, N.W.).—At Wednesday's meeting of the Vestry the report of the Financial Committee recommended that £75,000 be borrowed from the National Bank at 3 per cent. interest, mainly for the Vestry's electricity scheme. It was explained that the total saving effected by obtaining this money from the Bank instead of from the London County Council would be £5,626. Repayment is to be spread over a period of 42 years. The initial expenses of the loan from the Bank will be £102. In the course of the discussion the chairman (Mr. Churchwarden J. Thornley) stated that an additional loan of £100,000 would shortly be required for a further extension of their electricity works. It was decided to approve the Finance Committee's recommendation.

Sale (Cheshire).—At the last meeting of the District Council a letter from the Altrincham and Bowdon Electric Lighting Company, notifying their intention of applying for a Provisional Order to light the district by electricity, was referred to the Parliamentary Committee.

Scarborough.—The Sanitary and Lighting Committee of the Town Council have considered a proposal from the Scarborough Electric Supply Company (Limited) for lighting certain streets in the borough by electricity at an annual cost of £915. 5s., but recommend that the matter be not entertained for the present—a decision which has been confirmed by the Council.

Selangor (Straits Settlements).—The local passenger station at Kuala Lumpur has been installed with the electric light by Messrs. Howarth Erskine (Limited), whose electrical engineer, Mr. G. E. V. Thomas, has supervised the work. The same firm have completed installations of a similar character at Saigon, Bangkok and Singapore, and have in hand the lighting of the smelting works of the Straits Trading Company at Pulau Brani, Singapore. Brush generating plant has been put down at Kuala Lumpur, where five 2,000 c.p. arcs and about 70 incandescents are used. It is considered probable that this installation will be the forerunner of a complete electric lighting scheme for the town, which is one of considerable importance.

Sevenoaks.—The Guildford Electric Supply Company (Limited) have notified the District Council of their intention to apply to the Board of Trade for a Provisional Order to supply electricity for public and private lighting within the district.

Shoreditch (London, E.C.).—The Board of Guardians have replied to the Vestry's inquiry as to the supply of current for lighting the workhouse to the effect that they would prefer to have the supply under their own control. The Vestry thus loses a good customer unless the Guardians can be induced to alter their views.

Southport.—The Local Government Board has sanctioned the borrowing of an additional sum of £14,428 for electric lighting purposes by the Town Council.

Spain.—The Barcelona Tramways Company is considering the question of substituting electric for horse traction.

Sport.—Two members of the electrical profession were successful in obtaining awards at the Amateur Athletic Championship Meeting at Stamford Bridge Grounds, S.W., on Saturday last, the third and fourth places in the high jump championship being secured respectively by Mr. P. S. Perry, of Crompton and Co., and Mr. W. E. Lane, of the Brush Company, both gentlemen being awarded the standard medal of the Amateur Athletic Association.

Telephone Trunk Lines.—The Post Office intimates that on Monday next, the 15th inst., the Department's new trunk lines for telephone working will be open for use by exchange subscribers and private wire-renters of the Department, or by members of the public using the call offices at the various post offices affected. It has also been arranged with the National Company that subscribers to that Company's exchange system shall be allowed to use the Post Office trunk wires through the Company's exchanges for conversations between the more important towns in the kingdom.

The Lighting of Harbour Approaches.—The installation of a double row of electric lamps on either side of the Gedney Channel, Sandy Hook, has, it is stated, converted that narrow passage, hitherto only navigable at great risk after dark, into a well-lighted thoroughfare and easy of approach. The high-pressure cable is under water and 6½ miles in length, and posts attached to floating buoys keep the electric lamps at a level of about 12ft. above the water.

Tonbridge.—The Guildford Electric Supply Company (Limited) have notified the District Council of their intention to apply for a Provisional Order to supply electric current within the district.

Torquay.—The Guildford Electric Supply Company (Limited) and Edmundsons (Limited) have both notified the Town Council of their intention to apply for Provisional Orders to enable them to supply electric current within the area of the Council's jurisdiction.

Tunbridge Wells.—At the last meeting of the Town Council the report of the Lighting Committee, which recommended the expenditure of an additional £12,000 in electric lighting extensions, was adopted, and it was decided to apply to the Local Government Board for sanction to borrow this sum. In reply to a question, Councillor Wood said that the electric current would be turned on as soon as the alterations to the Town Hall had been completed.

Tunnel Lighting.—The Glasgow Harbour Tunnels, which were opened for traffic last week, are lighted by electricity, incandescents being used. The installation was carried out by Messrs. Paterson and Cooper.

Waterloo with Seaforth (Liverpool).—The Guildford Electric Supply Company and the Liverpool District Electric Lighting Company have both notified their intention of applying for powers to supply this district with electric current.

Whitechapel.—At the last meeting of the Board of Works notice was received from the Capital and Counties Electric Supply Company (Limited) of their intention to apply for a Provisional Order to supply electric current to the district.

Wimbledon.—At the last meeting of the District Council, on the recommendation of the Roads and Drainage Committee, it was decided to send out circulars to occupiers of houses of £40 rateable value, inquiring how many lights they would be prepared to take if the electric light were introduced into the district by the Council. The Chairman stated that when a previous scheme was introduced 480 similar circulars were sent out, and 190 replies (representing 1,202 lights) were received. Mr. Preece's scheme gave the cost of each 8 c.p. lamp at 10s per annum, exclusive of fitting up, and in the 1890 scheme the cost of wiring was estimated at from 20s. to 30s. per lamp.

Worcester.—The reduced scale of charges for electric current for motive power purposes has been agreed to by the City Council. The Deputy Mayor, in proposing the reduction, said that they had already a full night load, and the alteration was made in order to encourage the development of a day-load. At the same meeting the Deputy Mayor stated that he had no doubt whatever of the financial success of the electricity scheme.

COMPANIES' MEETINGS.

United River Plate Telephone Company (Limited).

The ninth annual ordinary general meeting of this Company was held on Tuesday at Winchester House, Mr. J. Irving Courtenay (Chairman), presiding.

The SECRETARY (Mr. Robert Herring) read the notice calling the meeting.

The CHAIRMAN said: Gentlemen, in moving the adoption of the report and accounts for the year ended March 31st last, I have much pleasure in congratulating the shareholders upon the improved position of the Company, and in finding that the expectations I ventured to set forth at the meeting last year have been, to a fair extent, realised, so that the Directors feel justified in recommending a dividend of 3 per cent. on the Ordinary share capital. The condition of affairs in the Argentine Republic is a subject of such interest to so many people in this country as to occupy a large space among the topics which are discussed with intelligence and thoroughness in the daily and weekly Press, and upon which you all thus have a full opportunity of forming an opinion. The advices from the Company's representatives in the River Plate point, in spite of frequent fluctuations, to a distinct general improvement in business there. The tendency in all directions is towards a permanent improvement; but we must not shut our eyes to the hindrances there are to a rapid return of prosperity, especially the existence of an enormous amount of paper money. The depreciation of this paper is, as the accounts testify, a source of serious loss to our Company; but we must face it, and deal with the position as best we can. The collections for the year under review, £149,262. 2s. 9d., are the largest we have ever had for a similar period, and, taking everything into consideration, cannot but be deemed to be most encouraging. The number of subscribers has increased from 5,363 to 5,798 on March 31st last, and the increase continues. Upon this point Mr. C. H. Krabbé, one of our consulting Directors in the River Plate, who was with us the year before last, and whose partner, Mr. Mold, is with us to-day, writes:—"Every day the telephone is becoming more of a necessity and less of a luxury; and so we go on getting a very satisfactory and steady increase in subscribers, and I see no reason why this should not go on in the future." I said, when I addressed you last year, that we must be prepared for a substantial increase in working expenses. There has been an increase in many items of expenditure, but the bulk of it is due to a general rise in wages. Then, again, the increase of subscribers has caused a larger amount of work, and has necessitated a corresponding increase in the number of electricians and linemen. In the construction and maintenance department our force has been extremely busy, and considerable modifications, alterations, and repairs have been made to our plant and wayleaves. Constant repairs and alterations are rendered necessary by the building operations that are in progress. The severe storms, more particularly those of October 16th, January 5th, and March 25th, did a great deal of damage to our wayleaves, and caused a large sum to be spent upon repairs. The repair of the La Plata plant has been the most important work in the maintenance department; in fact, we are building entirely new La Plata lines, and other important suburban work is in course of execution. The general condition of the branch offices is satisfactory. We have had to increase the capacity of the switchboards to keep pace with the increase of subscribers. This increase has been especially great at the central office, and has made the work there very heavy. Our employees have been called upon to exert themselves to the utmost, and have done so willingly and with excellent results. Especial commendation is due to our general manager in the River Plate, Mr. Chappell, and his able assistant in Buenos Ayres, Mr. Parker. The progress of the province of Buenos Ayres Telephone Company, in which, as you see from the balance sheet, we hold a considerable share interest, is reported to be quite satisfactory. As in previous years, the Directors have transferred the sum of £3,000 standing to the credit of the depreciation and renewal fund to the credit of cost of conversion of Seven per Cent. Debentures and issue of Five per Cent. Debenture Stock; reducing the balance of that account to £14,209. 13s. 8d. I wish to add that the investments are taken at cost, which is less than their present market value. The liability on bills receivable discounted, viz., £4,000, does not now exist, as the bills have run off in due course. I have briefly called your attention to the various matters that appeared to me to deserve comment, and I now beg to move—

"*That the report and accounts submitted to this meeting be, and they are hereby received and adopted, and that the Company declare the dividend recommended in such report, namely, 3 per cent. on the Ordinary share capital for the year ended March 31, 1895, payable on the 10th inst.*"

Mr. FRANK W. JONES (Managing Director), in seconding the resolution, said he thought it was a matter for congratulation to the shareholders, as well as the Board, that they were able on that occasion to recommend the proposed dividend, and there seemed every reasonable probability that they would not fail to do as well in the future.

The resolution was then adopted unanimously.

The CHAIRMAN proposed the re-election of Mr. Frank W. Jones, one of the retiring Directors.

Mr. J. OWEN UNWIN seconded the proposition, and it was agreed to unanimously.

The CHAIRMAN next proposed the re-election as a Director of Mr. Alfred Le Rossignol.

Mr. J. E. KINGSBURY seconded the proposition, which was also carried unanimously.

Mr. BISHOP moved the reappointment of Messrs. Cooper Bros. and Co. as auditors at a fee of 25 guineas.

Mr. F. A. BILLETER seconded the motion, and it was adopted.

Mr. FRANK W. JONES said he thought they should pass a resolution approving the conduct of their general manager in the River Plate, Mr. Chappell, and his assistant, and also to their able consulting Directors on the other side, Messrs. Fels and Krabbé. He would therefore move—

"*That the thanks of the meeting be given to the General Manager in the River Plate, Mr. Chappell, the Buenos Ayres manager, Mr. Parker, and their general staff; also to the local consulting Directors, Messrs. Fels and Krabbé, for the ability and zeal with which the business of the Company in the River Plate has been conducted during the past year.*"

Mr. F. A. BILLETER seconded the resolution.

The CHAIRMAN, before submitting the resolution to the meeting expressed a hope that it would be carried with cordiality, as they were much indebted to the gentlemen referred to in it for the successful position the Company had attained.

The resolution was then carried *nem. con.*

Mr. MOLD, in acknowledging the resolution on behalf of his partner, Mr. Krabbé, remarked that he did not think he could add anything to what the Chairman had said. He felt no hesitation, however, in confirming all that the Chairman had said with regard to the Company's prospects in the River Plate, always provided that no unexpected catastrophe took place. There was no doubt that the progress made last year in the number of subscribers, which was the essential point, continued. The premium on gold seemed at present to be working in favour of the Company, and he sincerely trusted it might continue to do so.

Mr. J. OWEN UNWIN then moved a hearty vote of thanks to the Chairman and Directors for their able management of the Company's affairs.

Mr. J. E. KINGSBURY seconded the motion, and it was unanimously carried.

The CHAIRMAN, in reply, said: I thank you heartily for the vote of thanks you have just given us. It is, of course, very pleasant for us all, shareholders and directors alike, that this Company, after a hard fight for five years, has again, by to-day declaring a dividend, re-entered the dividend-paying list, and I hope it may long remain there.

The proceedings then terminated.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1895, pages *304-332, &c. &c.*]

AMAZON TELEGRAPH COMPANY (LIMITED).—This Company was registered on July 5th with a capital of £250,000, in £10 shares, to acquire and carry out a concession from the Government of the United States of Brazil, dated April 29, 1895, for the establishment and working of telegraphs in the States of Pará and Amazonas (United States of Brazil), to establish, or acquire, construct, work, and maintain sub-fluvial or other electric telegraphs or telephones in the said States or elsewhere, to acquire and obtain from the Brazilian Government or from the said States of Pará or Amazonas, or either of them, or from any other Government, State or Power, any existing or other concessions, powers, rights and privileges, for the purposes of, or in furtherance of, or in connection with any of the objects of the Company, and to enter into working or other arrangements with any telegraph or other company, or person, or with any Government upon any terms and conditions. The subscribers are:—

	Shares.
W. S. Andrews, 18, Old Broad-street, London, E.C. (Chairman of the Western and Brazilian Telegraph Company, Limited)	200
Lord Richard H. Browne, Reigate, Surrey, Director of Western and Brazilian Telegraph Company	100
John Coppen, Ashford, Middlesex, Director of Western and Brazilian Telegraph Company	400
D. H. Goodsall, 17, Devonshire-place, W., Director of Western and Brazilian Telegraph Company	200
Alexander Wood, Abbey Wood, Kent, Managing Director of the Western and Brazilian Telegraph Company (Limited)	500
R. M. Cunningham, Blomfield House, London Wall, London, E.C., Secretary of the Western and Brazilian Telegraph Company (Limited)	100
E. S. Hodson, "Lamorna," King Charles-road, Surbiton, Surrey, accountant	1

The first Directors are:—W. S. Andrews, Lord Richard H. Browne, C. W. Earle, J. Coppen, D. H. Goodsall, and Major Alexander Wood. Qualification for office: the holding of shares or stock of the nominal value of £1,000. Remuneration, £1,500 per annum, to be divided between them as the Directors themselves determine. Registered office, Blomfield House, London Wall, London, E.C.

HARROW ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—This Company was registered on July 5th with a capital of £25,000, in shares of £5 each, to carry on at Harrow-on-the-Hill, Middlesex, or elsewhere, the business of an electric light and power company in all or any of its branches, and of manufacturers and suppliers of electricity, and to take a transfer of all or any of the powers, duties, and liabilities granted

Digitized by Google

to and imposed upon the undertakers under the Harrow Electric Lighting Order (1894), and of any other authority granted or to be granted for the supply of electricity in Harrow or its neighbourhood, and to carry the same into effect. The subscribers, with one share each, are: J. G. C. Welldon, head master of Harrow School; C. Colbeck, E. R. B. Denniss, R. C. Gilson, E. W. F. Stiven, M.D.; F. S. Winkley, and A. P. Charles. The first Directors are: C. Colbeck, E. R. B. Denniss, R. C. Gilson, E. W. F. Stiven, M.D., and F. S. Winkley.

ALBERT ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return to November 14th has been recently filed. Out of a nominal capital of £10,000, in shares of £5 each, 407 have been taken up, and the full amount has been called on 400, while a call of £1 per share has been made on the remaining seven.

ALLIANCE METER COMPANY (LIMITED).—The statutory return to June 12th has been filed. The nominal capital is £5,000 in £1 shares, and of these 2,007 have been taken up; 2,000 have been issued as fully paid to William Coward, and the full amount has been called on the remaining seven shares, but has not yet been paid in.

AUTOMATIC ELECTRIC RAILWAY SIGNAL COMPANY (LIMITED).—The annual return to May 2nd has been filed. The nominal capital is £10,000, in £1 shares, and of these 5,940 have been taken up: 4,300 shares have been issued as fully paid, and the full amount has been called and paid on the remainder.

BAILY, GRUNDY AND BARRETT (LIMITED).—The annual return to June 4th has been filed. The nominal capital is £10,000, in £5 shares, of which 662 have been subscribed for and allotted. The full amount per share has been called and paid.

BENHAM AND FROUD (LIMITED).—The annual return to May 14th has been filed. Out of a nominal capital of £50,000, in £10 shares, 2,907 have been subscribed for and allotted, and the full amount has been called and paid thereon.

BROWETT, LINDLEY AND CO. (LIMITED).—The annual return to April 22nd has been filed. The nominal capital is £20,000, in 1,600 Ordinary and 400 Preference shares of £10 each; 1,362 of the former and 200 of the latter class have been taken up, and 800 have been issued as fully paid. The full amount has been called and paid on the remaining 762 shares.

DENISON AUTO-TELEGRAPH MACHINE SYNDICATE (LIMITED).—The statutory return to November 21st has been filed. The nominal capital is £1,000 in 20 shares of £50 each. Of these 16 have been subscribed for and allotted, and eight have been issued as fully paid. The full amount has been called on the remaining eight shares.

CITY NOTES.

AMAZON TELEGRAPH COMPANY (LIMITED).—The prospectus has been issued this week of the above Company, which is formed to connect by cable the city of Manaos, the capital of the State of Amazonas, with the city of Pará, at the mouth of the river Amazon, with a number of intermediate stations or branch lines. At Pará the Company's cable joins the land lines of the Brazilian Government and the cables of the Western and Brazilian Telegraph Company, thereby completing the connection with the rest of Brazil and the Argentine Republic, and by means of the cables of the Brazilian Submarine Telegraph Company communication with Europe and the whole telegraphic system of the world is secured. The capital of the Company is £250,000, in shares of £10 each, payable £1 on application, £2 on allotment, £2. 10s. on September 16th, £2. 10s. on November 15th, and £2 on January 15th next. The Company starts with an annual subsidy granted by the Brazilian Government of £17,125 per annum for 20 years, payable quarterly in gold; and the Directors prove their confidence in the success of the Company by personally subscribing for £12,000 worth of the shares at par. At the expiration of 30 years the Company's system reverts to the Federal Government, which has power to purchase after 10 years at a price to be agreed upon. The prospectus points out that an attempt made by the Brazilian Government to effect a land-line communication with the points now attached by the cable has, owing to difficulties experienced in the forests and swamps bordering on the river, proved unsuccessful, and has had to be abandoned. The contract for making the cable has been placed with Messrs. Siemens Bros. and Co, who will provide the apparatus, repairing machinery, &c., and hand the system over complete and in working order for the sum of £211,000, to a specification approved by the Company's engineers and electricians, Messrs. Clark, Forde and Taylor. The total length of the cables is about 1,365 miles, and the contract time for completion is March 1st next. Calculations are made which show a net revenue equal to over 10 per cent. interest on the capital. The Chairman and Directors of the new Company are the Chairman and Directors of the Western and Brazilian Company, and Mr. R. M. Cunningham, Blomfield House, London-wall, London, E.C., is secretary. The subscription list closed on Wednesday last, and we understand that the capital was over-subscribed.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ending July 7th were £915, as against £879 in the corresponding week of 1894, being an increase of £36.

CAPE TOWN AND SUBURBAN ELECTRIC LIGHTING SYNDICATE (LIMITED).—Messrs. Davis and Soper notify the payment of a dividend at the rate of 7 per cent. per annum by this Syndicate.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—The transfer books and register of members of the Six per Cent. Preference shares of this Company will be closed from the 15th to the 24th July inclusive, for the purpose of preparing the interim dividend warrants. This interim dividend for the six months ended June 30th last is payable on and after the 25th inst. The gross revenue returns of the Company for the quarter ended June 30, 1895, is as follows:—Sale of current for public lighting, £3,501, against £3,162 in the corresponding period of 1894; private lighting, &c., £12,283, against £7,153; other sources, £200—total, £15,984, again £10,315—an increase of £5,669. The equivalent of 8-c.p. lamps connected on June 30, 1895, was 159,250, against 99,140 on June 30, 1894. The increase of 8-c.p. lamps connected during the past quarter was 10,656 against 15,927 in the corresponding quarter last year.

DIRECT UNITED STATES CABLE COMPANY (LIMITED).—The Directors of this Company have resolved to recommend a final dividend of 2s. per share, free of income tax, payable on and after the 31st inst. This makes, with the interim dividends already paid, 2 per cent. for the year ending June 30th last, and after placing £7,000 to reserve fund account, a balance of £1,410. 0s. 9d. is carried forward. The transfer books will be closed from the 15th to the 30th inst. inclusive.

EASTERN TELEGRAPH COMPANY (LIMITED).—Subject to final audit, the accounts of this Company show, after placing £100,000 to the reserve fund, a balance available sufficient to pay at the forthcoming general meeting the fixed dividend of 3s. per share, being at the rate of 6 per cent. per annum on the Preference shares, less income tax, and a final payment of 2s. 6d. per share, with a bonus of 3s. per share, both free of income tax, on the Ordinary shares, making, with previous payments on account, a total distribution of 6½ per cent. on those shares for the year ended March 31, 1895. The transfer books will be closed from July 18th to 25th inclusive.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The interest on this Company's Four per Cent. Mortgage Debenture Stock for the half-year ending 31st inst. will be paid on August 1st. The Four per Cent. Mortgage Debenture Stock register will be closed from the 27th to the 31st inst. inclusive.

ELEKTRIZITATS AKTIEN-GESELLSCHAFT (vormals Schuckert and Co., Nuremburg).—The Board of this Company is proposing a dividend of 10 per cent. for last year, as against 9 per cent. for the previous year.

GLOBE TELEGRAPH AND TRUST COMPANY (LIMITED).—A further distribution of 3s. 3d. per share is announced on the Ordinary capital of this Company, leaving about £1,200 to be carried forward.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this Company for June were £25,200, and the total receipts during the period from January 1st to June 30th were £149,200, as against £132,800 and £129,800 in the corresponding periods of 1893 and 1894 respectively.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended the 7th inst. amounted to £1,250. The amount for the corresponding week last year was £917; increase, £333.

MAUDSLAY, SONS AND FIELD (LIMITED).—The report of the Directors of this Company, just issued, states that the results of the past year's working do not admit of payment of dividend on the Preference shares.

NATIONAL TELEPHONE COMPANY (LIMITED).—The transfer books of the Preference and Ordinary shares of this Company will be closed from the 13th to the 26th inst. inclusive. The dividend warrants will be posted on the latter day.

REDUCTION OF CAPITAL.—Notice is given that the Order of the Chancery Division of the High Court of Justice, dated June 25, 1895, confirming the reduction of the capital of Crompton and Co. (Limited) from £300,000 to £280,000, was registered by the Registrar of Joint Stock Companies on the 5th inst.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee appointed Wednesday last, July 10th, a special settling day for £120,000 Four and a-Half per Cent. Twenty-Year First Mortgage Debentures (Nos. 1 to 1,200) of the Royal Electric Company of Montreal, and have ordered the same to be quoted in the official list. The Committee have also appointed Wednesday, July 17th, as a special settling day for 11,303 Seven per Cent. Cumulative Preference Shares (Nos. 1 to 11,303) of the British Aluminium Company (Limited).

SUBMARINE CABLES TRUST.—Notice is given that on and after the 15th inst. the sum of £1. 5s., balance of the coupon due April 15th last, will be paid by Messrs. Glyn, Mills and Co., Lombard-street, E.C. Coupons to be left four days for examination.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY (LTD.).—The Directors of this Company have declared an interim dividend of 12s. per share.

VAN HECKE'S FUEL ECONOMISER SYNDICATE (LIMITED).—An extraordinary general meeting of this concern was held on Wednesday to consider a proposal that debentures should be issued for the payment of principal sums not exceeding £10,000, and also to increase the capital of the Company to £25,200 by the creation of 2,000 new shares of 2s. each. Capt. Bickford, who presided, said that the vendors had assigned the patents to the Company. The apparatus was in use on the District Railway, and the Directors had received an order to fit one of the Great North of Scotland engines for trial. A large measure of success had been achieved in France, and about 50 contracts had been entered into, among which were those with the Naval Department and the War Office. The proposal was approved.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended July 5th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,969.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 896. [No. 12. Vol. XXXV.] FRIDAY, JULY 19, 1895. PRICE SIXPENCE.

NOTES.

A SOMEWHAT larger shower than usual of notices of intention to apply for electric lighting Orders appears this year to have fallen upon the various local authorities of the United Kingdom. Perhaps the institution of District and Parish Councils has something to do with it; at any rate many of these infant local governing bodies seem not a little puzzled as to what may be the correct attitude to adopt under the circumstances. They have been educated in the orthodox faith that nothing that a local authority can possibly do at a loss should be done by a company at a profit; nevertheless, as business men the members see very well that the electric lighting of English villages, even on a perfect system, is likely for the most part to prove a decidedly hazardous venture. Such being the case, doubtless much will be attempted either by public or private enterprise that had better have been let alone, and many a village community may spring at a single bound from the petroleum lamp to the glow lamp. Caution in these matters is the better part of permanent progress.

LITTLE did Prof. DOLBEAR know what he was bringing upon himself when, in the lightness of his heart, he wrote to the *Electrical Engineer* of New York last May to claim for Prof. TROWBRIDGE, of Harvard, "whatever merit and utility" there may be in connection with the origination of "doing telegraphic work by means of earth conduction." Mr. PREECE, so far as we are aware, makes no claim to have been the first to have *thought* of telegraphy without wires. On the other hand, he has certainly been the first to persistently experiment in this direction, and to attain anything approaching practical success. Moreover, judging by the titles of many of his Papers, and by their contents, he does not think that "earth conduction" plays any appreciable part in the matter, pinning his faith to "induction," though conclusive experiments with two completely-metallic thoroughly-well insulated circuits are wanting. But however this may be, priority in suggesting telegraphy without wires belongs, it would appear, to this side of the Atlantic. That veteran telegraphist, Mr. J. W. WILKINS, states in a letter to be found in our "Correspondence" columns this week that he publicly suggested the idea of wireless telegraphy between England and France so far back as 1849, having previously made some tentative experiments with the aid of a moving-coil galvanometer of his own design. Mr. WILKINS, we are glad to see, is not inclined to attach over much importance to a mere suggestion, even when, as in his case, it had for basis considerable experiment and the invention of a now indispensable form of instrument; neither does he imply, as does Prof. DOLBEAR on behalf of Prof. TROWBRIDGE, that his work has been intentionally ignored. As Mr. WILKINS puts it, "it cannot be expected that everyone shall get to know what everyone else has done in any particular direction."

To all who like vigour and sprightliness of expression we commend the article on "English Internationalism," by M. HOSPITALIER, a translation of which will be found in another column. The subject of magnetic symbols and nomenclature threatens to become a trifle wearisome even to those whom such things interest; and our further reference to the matter shall be brief. We asserted that modern magnetism took its growth in England. The correctness of this statement is admitted, but its modesty, alas, is impugned. Furthermore, in Royal Society Papers of 1885 M. HOSPITALIER can find no block letters, the use of which to denote magnetic quantities had, we alleged, become well established in this country. That is not surprising; Maxim guns are not to be found in a battle-piece of a century ago. A glance at Prof. SILVANUS THOMPSON's "Dynamo-Electric Machinery" of 1892, or Prof. EWING's "Magnetic Induction in Iron and other Metals" of 1891 will reveal the existence of block letters in sufficient quantities to support our contention. As to M. HOSPITALIER's remarks on the use of the term "gauss" in two senses, there is surely no need to again travel over our ground; are not our arguments to be found on pp. 144 and 282 of the present volume? M. HOSPITALIER would appear to think that the consideration of the convenience of printing offices in the matter of type is beneath the dignity of science. Possibly it is; but a little less dignity and a little more attention to such common-sense considerations would tend to oil the wheels of progress. As a matter of fact, however, we do not believe there is any foundation for the suggestion that a parsimonious printer was the proximate cause of the introduction of block letters. Finally, M. HOSPITALIER seems to imply that we have doubts as to the utility of international symbolism. We have none whatever. We merely desire to "hasten slowly," and to make sure that the resounding adjective "international" shall be something more than a synonym for "French," such as it is, for instance, in connection with the so-called Société Internationale des Elec-

Digitized by Google

triciens. It is quite possible that truly international sanction may ultimately be given to $\mathfrak{B}$'s, $\mathfrak{H}$'s, and $\mathfrak{J}$'s, and that we may even then still be guilty of the heresy of saying a mistake had been made; but we should, nevertheless, loyally acquiesce in any authoritative decision, and make immediate use of the execrable symbols M. Hospitalier so much affects.

In a Paper by Dr. Werner Bolton, the gist of which we give elsewhere, an impressive array of evidence is adduced in favour of the belief that a dilute solution of mercuric iodide in potassium iodide contains monovalent mercury ions, that is to say, behaves in the manner proper to a solution of mercurous iodide. This startling result is arrived at by consideration of the fact, experimentally established by Dr. Bolton, that dilute solutions of mercuric iodide show an amount of electrolytic change (consisting in solution and corresponding deposition of mercury) approaching that taking place in a mercury voltameter in which the mercury is in the mercurous condition and included in the same circuit. The neat and satisfactory conclusion that a certain further dilution, deduced from the curve representing the results observed, would suffice for the completion of the change of valency, was not realised by experiment, that modicum of original sin present in all matter, living or dead, doubtless serving to defraud the investigator of a deserved consummation. While admitting the solid character of the data from which Dr. Bolton draws his conclusions, we confess that it appears eminently desirable to obtain collateral evidence, involving physical and chemical considerations wholly distinct from those concerned in the present experiment, before finally accepting the view that actual change of valency may occur by mere dilution. Possibly the continuation of the same research with copper in place of mercury will meet this requirement.

An interesting feature of Mr. H. T. Haws' Paper, recently read before a students' meeting of the Institution of Electrical Engineers, is the criticism of the electrical profession which the author indulges in. We reprint the Paper in another column, and our readers can therefore themselves peruse Mr. Haws' caustic remarks. The sad fate of electric mining in England, as pourtrayed by Mr. Haws, is attributed to the lack of good electrical mining engineers, who, he says, can be counted on the fingers of both hands. There is undoubtedly a good field for our superfluous young electrical geniuses in this quarter; but the requirements are many and varied, combining, as they do, a knowledge of both mining and of electrical work. "There are plenty of men possessing the one and thinking they possess the other"; but the number possessing both qualifications seems, alas! to be only as per previous digital estimate. But if the outlook for mining applications is not altogether rosy, according to Mr. Haws the future of electric supply is to his mind much brighter; indeed, Mr. Haws would not "mind saying that in eight or ten years the electric light companies in London will work at full load day and night." Eight or ten years is, perhaps, rather a long time to wait for this rich harvest, and we are sorry that the author could not see his way to somewhat shorten the vogue of the lean kine; but even as it is, he has left the supply companies time enough before the expiry of their 42 years of grace to feather their nests very warmly.

Several important points are raised by the action, reported in another column, brought by the Direct Spanish Telegraph Company against the owners of the s.s. "Caloric." The Master of the Rolls, in one of his numerous interruptions of the plaintiffs' counsel, called the plaintiffs' cable "a beastly serpent;" and certainly in his remarks showed little sympathy for the very serious loss occasioned by the action of the captain of the "Caloric," whether justifiable or otherwise. It is clear from the evidence that an amendment of the Submarine Telegraphs Act is necessary, and nothing short of a positive prohibition against anchoring within a certain distance of a cable in shallow waters will be any protection to cable companies' property; and where cables are lying in bays or harbours, or in proximity to the coast, it is advisable that a provision should be made for the marking, either by buoys or on authorised charts, of the approximate course of submarine cables. At present most inadequate protection is afforded by the Convention of 1885.

Electrical engineers will no doubt be glad to learn that "Mr. Hogan, of the Yale Psychological Laboratory," has, according to the *Daily Chronicle*, made "a discovery of considerable value." Mr. Hogan, we are assured, "finds that by an instrument, the details of which are not made public, patent rights being meditated, he can readily utilise the high voltage city current for low voltage instruments like those employed in telegraphy, telephones, electric forks, bells, induction coils, &c." This discovery, we are further told, supplies a long-felt want, and will tend to advance "the use of the latest illuminant." Possibly!

Cable Interruptions.—There are no cable interruptions to report this week.

Verband Deutscher Elektrotechniker.—The membership of this Association has increased in the last year from 765 to 1,543.

Post Office Trunk Telephone Lines.—The trunk telephone wires of the Post Office were opened for use to the public on Tuesday last.

University College, Bristol.—The 1895-6 session of this College commences on October 3rd. Further particulars appear in our advertisement columns.

Yorkshire College, Leeds.—The next session begins on October 8th; and some particulars of the Electrical Engineering course appear elsewhere in our columns.

Owen's College, Manchester.—This College gives complete instruction in the Physics Department to students preparing for the electrical profession. Special courses of lectures are delivered, the subjects including Dynamo Design.

University College of North Wales, Bangor.—Prof. A. Gray begins a systematic course of instruction in Electrical Measurement and Practical Electricity in October next. Additional particulars will be found in our advertisement columns.

The Maxim Glow Lamp Patent.—On Sunday, the 21st, the legal existence of the Maxim glow lamp patent, No. 3,189 of 1881, comes to an end. This patent related to a method of manufacturing glow lamps, involving improvements in the sealing of the wires into the globe, and in the preparation of the carbon strips and certain accessory devices. There were 17 claims.

Digitized by Google

King's College.—It is announced that King's College, London, will shortly open a new department for the training of teachers for secondary schools. The course is spread over two years, and may be attended by students concurrently with their preparation for the B.A. degree of the University of London. Six exhibitions are offered for competition. Names of candidates are to be sent in before September 16th.

Budapest Tramway Company.—With reference to our Note in last week's *Electrician* regarding the above, we may say that Messrs. Siemens and Halske, of Berlin, have secured the contract for the electrical equipment of all the lines. In the town the conduit system, as already installed on one line, will be used, and in the suburbs the overhead system will be applied. All cars will be so arranged that they can easily change over from one system on to the other.

Telephonic Experiments with Solar Radiation. — M. Semmola shows in a recent number of the *Comptes Rendus* that on causing intermittent sunlight to fall, by means of a lens, on the gilded metallic plate, 2mm. thick, of a Hunnings microphone, the telephone put in circuit produces a slight but very distinct sound. If the luminous ray be suppressed, the sound ceases. The intensity of the sound increases or decreases according as the intermittences of the radiation becomes more or less rapid. The best radiations are the thermal radiations.

Firth College, Sheffield.—The *Athenæum* says that the town trustees of Sheffield have voted a sum of £10,000 towards the endowment of Firth College, with a view to enabling the authorities to affiliate it to Victoria University. The actual endowment of the college is £23,000, in addition to its income of £12,000 from the State and £800 from the Corporation. It is understood that a total of £50,000 would be sufficient, but no more than sufficient, for the purpose of affiliation. A further sum of £5,000 has been conditionally promised by Sir Henry Stephenson, and a public appeal is contemplated for the remaining £12,000.

An Electrical Automatic Marine Fog Signal.—A marine fog signal, the invention of Mr. F. H. Berry, of 14A, Clerkenwell-green, has been fitted to the British India Steam Navigation Company's steamship "Dunera." The object of the apparatus is to give, at the regular interval required by law in case of fog, the whistle or bell signals. On the bridge of the vessel is mounted a switch, by turning which the officer in charge can cause an electric current to actuate either the whistle or the ship's bell at regular intervals. The proper interval between the sounds is obtained by clockwork. At the same time that the whistle is blown or the bell sounded, a pen is brought into contact with a continuous band of paper, which is marked with divisions. As the paper is wound off at a uniform speed by the clockwork, an autographic record is obtained showing when the fog signals, by bell or whistle, are sounded. On Monday the apparatus was worked experimentally in the presence of certain Government officials and officers of the British India Steam Navigation Company.

The Cox Thermo-Electric Generator.—In an article in a recent issue of the *Electrical Engineer* of New York, an illustrated description is given of the Cox thermo-electric generator. The main point of this apparatus appears to be that the oxidation of the junctions is overcome by having practically no real junction point, for what in ordinary cases is a junction is in this apparatus so formed as to produce what is termed a graduated alloy; that is, two alloys composing the element are graduated one into the other so that there is no real point of junction. To prevent the oxidation of the metals by the atmosphere the complete element is cased in cement, which is afterwards vitrified. No mention is made of the nature of the alloys employed. A Cox thermo-electric generator consuming 1½ft. of gas per hour and weighing complete 3lb., and being 1¾in. high, 1in. internal diameter and 4in. external diameter, has been found to have a useful output of 5·5 amperes at 5 volts. It is stated that with a total gas expenditure of about 7 cubic feet per hour the New York office of the Commercial Cable Company operated its entire lines for several weeks with these generators, and that as a result of the trial the Company's entire system is to be equipped with them.

Science Research Scholarships.—Her Majesty's Commissioners for the Exhibition of 1851 have made the following appointments to science research scholarships for the year 1895, on the recommendation of the authorities of the respective Universities and Colleges. The scholarships are of the value of £150 a year, and are tenable for two years (subject to a satisfactory report at the end of the first year) in any University at home or abroad, or in some other institution approved of by the Commissioners. The scholars are to devote themselves exclusively to study and research in some branch of science, the extension of which is important to the industries of the country:—

Nominating Institution.	Scholar.
University of Edinburgh	John D. F. Gilchrist, M.A., B.Sc.
University of Glasgow	Walter Stewart, M.A., B.Sc.
University of St. Andrews	Henry C. Williamson, M.A., B.Sc.
University College, Dundee	James Henderson, B.Sc.
Mason College, Birmingham	Robert H. Pickard.*
University College, Bristol	Samuel R. Milner.
University College, Liverpool	John T. Farmer, B.Sc.
University College, London	Emily Aston, B.Sc.
Owens College, Manchester	William H. Moorby, B.Sc.
Durham College of Science, Newcastle-on-Tyne	Alexander L. Mellanby, A.Sc.*
University College, Nottingham	Martin E. Feilmann.
Queen's College, Belfast	William Hanna, M.A.
M'Gill University, Montreal	Robert O. King, B.Sc.
Queen's University, Kingston, Canada	Thomas L. Walker, M.A.
University of Sydney	John A. Watt, M.A., B.Sc.
University of New Zealand	Ernest Rutherford, M.A.

* Conditional appointments.

Hysteresis of Steel at Different Temperatures.—In a recent number of the *Proceedings* of the American Academy, Messrs. F. A. Laws and H. E. Warren publish the results of some experiments on the relation of hysteresis to temperature in the case of a specimen of steel. Alternating currents were used, and the losses determined by a wattmeter designed by the authors. The furnace used for heating the specimen was of fire brick and heated by three blast jets. The supplies of gas and air were regulated by slide valves. The jets were directed into the furnace tangentially and with a slight upward inclination, the effect being to establish a good circulation and keep the interior of the furnace at a uniform temperature. The specimen was composed of so-called French steel, which showed on analysis over 0·5 per cent. of manganese and 0·97 per cent. of carbon, with traces of phosphorus, silicon, and sulphur. Temperatures were determined by a Le Chatelier pyrometer. The experiments showed that for this sample of steel a moderate elevation of temperature up to about 270deg. had but a small influence on the hysteresis loss; that at this point a change takes place, and the diminution of hysteresis, with rise of temperature, is much more rapid, the decrease being such that at 675deg. the loss is but 13 per cent. of its value at ordinary temperatures. After heating above the inflection point the specimen showed on cooling a marked decrease of the hysteresis loss from its value at the same temperature on the ascending curve. If the specimen be heated again, a change of direction of the curve takes place, but at a lower temperature. Other measurements showed that there is practically no change of hysteresis for a diminution of temperature to about −80°C. The experiments are to be continued.

Colour Vision.—In the *Comptes Rendus* of July 8th, M. Georges Darzens put forward a theory of his own as to the physical perception of colour. In order to explain colour vision, Young and Helmholtz both assumed that each nerve which ran from the optic nerve to a cone was composed of three fine fibrils, respectively sensitive to red, green, and violet rays. This hypothesis, slightly modified by Clerk-Maxwell and by Fick, although it explains many facts, leaves many others quite as important without logical explanation. Thus it is somewhat difficult to conceive of an optical resonator being so accurately fashioned as to be excited by waves of say, 0·620 μ, and not at all by others slightly longer or shorter. M. Darzens' theory is as follows:—A luminous ray after having traversed the different layers of the retina usually reaches the pigmentary layer; there it is reflected and comes into interference with the incident ray. From this it follows that in front of the pigmentary layer inside the retina itself there is a system of stationary waves at a distance

Digitized by Google

of λ/2, as in the experiments of O. Wiener and those of Lippmann on colour photography. It is these stationary waves that excite the ends of the optic nerve—the rods and cones of the eye. M. Darzens then goes on to point out that the rods consist of cylindrical parallel fibrils of equal length, whilst the fibrils of the cones are of unequal length. One can, therefore, very well imagine that whilst the former merely give a sensation of light, the latter are the source of colour vision, a theory which is borne out by the fact that the *fovea*, the recognised centre of colour vision, is entirely composed of cones, and that the eye of night birds have no cones, whilst those of birds which live on coloured insects are rich in cones. The retina must thus no longer be considered as a mere laboratory screen, but as one which perceives different colours at different depths.

Effects of the Recent Lightning Flash in Ben Nevis Observatory.—The following are some of the particulars sent to *Nature* by Mr. William S. Bruce, with regard to the effects of the recent lightning flash which struck Ben Nevis Observatory:—

Whenever a thunderstorm passes the summit of the Ben, there occurs almost invariably a discharge from metallic bodies in the Observatory as the cloud is passing away. A flash of greater or less extent is given off the stoves, accompanied by a sharp crack. In January, 1890, there was an exceptionally severe flash; "one of the observers was almost knocked down when sitting writing, and the telegraph wire was fused and all communication stopped for five days." But more destructive than any previous flash was that which occurred this year on June 19th, when the Observatory narrowly escaped being destroyed by fire. Between two and three o'clock on that afternoon, repeated clicks on the telegraph instrument were heard by one of the assistants who was sitting in the office; he had been carefully noting the times at which the clicks occurred, when suddenly the whole office was filled with a brilliant flash and deafening roar. A pillar of smoke was discharged from the telegraph instrument and from the stove-pipe, filling the room. A second slighter discharge took place immediately after, when the writer had entered the office to commence the 15 hours' observations. The discharge hurled two boxes and a small picture, that were in the vicinity of the lightning protector, across the kitchen, and blew off the button and outer casement of the electric bell in the visitors' room. The solder on the kitchen chimney outside, a copper fastening of the lightning conductor, and many portions of the telegraphic wire and apparatus were fused, and the woodwork of the Observatory was scorched in several places. The great flash occurred at 14h. 57½min., and the hourly barometric reading was taken at 15 hours. as usual. There was a very heavy fall of snow at the time, equivalent to 0·470in. of rainfall for the hour, but in the confusion the writer omitted to take the rain-gauge with him, and had to return for it. This was a fortunate incident; for it was only on leaving the office for a second time that he observed smoke and flame issuing from behind the panelling between the kitchen and the office. Assistance was secured, and the fire—which was in a very awkward and dangerous place—was overcome in good time, and the damage done was very slight. The damage done to the telegraphic apparatus, however, was serious. The lightning protector was badly fused, the plates showing a patch of fusion as large as a sixpence. All connecting wires within the building were rendered useless. The majority were so heated as to melt the insulation off, and in one or two cases the copper conductors were melted by the discharge. In one case the fusion set fire to the woodwork. The coils of Neale's sounder were fused and rendered useless. The keys suffered worst of all. The vacuum protector at Aslimtee, the base of the cable, also the plate protector in Fort William Post Office, were fused, but only slightly, the main discharge having expended itself on the summit. The Low Level Observatory Instrument and protector were unimpaired, and communication between there and Fort William Post Office was carried on as usual after the removal of the fault in the Post Office protector. The registering aneroid shows a slight upward kick at the time, but the curve is otherwise fairly steady; the temperature was 31·7 F., the wind south-south-east and light. Heavy snow was falling at the time, which, with a fall on the 17th, made a total depth of nine inches on the summit. St. Elmo's Fire was very strongly felt and heard until after 17 hours.

The Niagara Falls Scheme.—From the confused accounts which reach us from time to time through both the daily and technical Press, it is somewhat difficult to disentangle what has actually been done from what it is proposed to do at Niagara. To this end we take the following facts from a lengthy and well illustrated account of "The Work that has been done at Niagara," which appeared in the *Electrical Engineer* of New York of June 26th. This account is unusually sober; but its writer is nevertheless constrained to commence as follows: "No one contemplating the scene of the falling waters at Niagara can fail to be inspired with the sense of power there concentrated, and even the savage, ignorant of applications of motive power, as he gazed upon the scene before the white man set foot within it, must have been imbued with a sense of the great force and constant action before him. Civilised man, however, &c., &c." The plan finally adopted by the Niagara Falls Power Company embraced, we are then told, the construction of a canal about 1½ miles above the American Fall, tapping the Niagara river. Wheel pits sunk along the edge of this canal lead the water to turbines at the bottom, the discharge being carried off through a 1¼ mile long tunnel, 19ft. by 21ft. high. Round about the Falls the Niagara Company has purchased land to the extent of 7,500 acres, which it is proposed to let out for the building of factories and residences. The power belonging to the Company may either be obtained by factory owners sinking their own wheel pits or by taking it from the turbines of the Company, or by having it electrically transmitted to them. The electric power station at present erected is designed for an ultimate capacity of 50,000 H.P., but at present only three 5,000 H.P. two-phase generators have been erected. The electrical equipment, as our readers no doubt recollect, was carried out by the Westinghouse Company, Prof. George Forbes acting as consulting electrical engineer. The generators have stationary armatures and rotating field-magnets, and develop at a speed of 250 revolutions a two-phase 25 ∾ current at a pressure of 2,250 volts. The armature core is made of thin oxidised iron plates, held together by eight nickel-steel bolts. In the outer edge of the plates are 187 rectangular holes, in each of which are placed two rectangular copper bars $1\frac{1}{4}$in. by $1\frac{5}{16}$in., surrounded with mica. The outer rotating bell-shaped field-magnet consists of a wrought-steel ring, to which are bolted 12 inwardly projecting massive cast-iron pole-pieces. The magnet winding is also composed of copper bars, air insulated. The turbines were designed by MM. Faesch et Piccard of Geneva, and special methods were adopted to relieve the bearings of the pressure of the superincumbent mass. The weight of the 50ft. long steel shaft, and attached portions of the dynamo, amounts to 68 tons; this shaft consists of a shell about a foot in diameter with solid portions at the journals. Large conduits have been provided on the Niagara Falls Estate for the purpose of taking current-carrying conductors to the *in futuro* factories. The internal dimensions of these conduits are 5ft. 6in. high by 3ft. 10in. wide, the conductors being carried on insulated brackets on the walls. A track extends throughout the length of the conduit, upon which an electrically propelled car will carry the linemen between the wire screens protecting them from the conductors. Judging from our contemporary's statement that "rights of way for a pole line to Tonawanda, directly north of Buffalo, have already been secured," it would appear that the underground conduit to Buffalo, which was the object of so much criticism at the hands of those who discussed Prof. Forbes' Institution of Electrical Engineers Paper, has been, at any rate temporarily, abandoned. At present there would appear to be one actual user of power, and two prospective ones. The actual user is the Pittsburgh Reduction Company, taking 2,000 H.P. electrically. As the reduction of aluminium necessitates the use of a continuous current, the following arrangement is employed. The 2,000 volt alternate current is taken to stationary transformers, and there converted into an alternating current of 115 volts pressure. This low-pressure alternating current is then led to rotary transformers and converted into a continuous current at 160 volts pressure. The plant of the Reduction Company will have a working capacity of 7,000 amperes. The prospective users of power are the Niagara Falls Paper Company, who have contracted for 6,000 H.P. developed from their own turbines at a cost of $9 per H.P per annum, and the Carborundum Company, who have erected works close beside those of the Pittsburgh Reduction Company, and will start with 1,000 H.P. All this relates to the work done on the American side of the Falls, but our contemporary states that plans are already complete for the utilisation of the Falls on the Canadian side. This work will be carried out by a company closely affiliated with the American Company, and the plans proposed by it have been accepted by the Canadian Government. These plans contemplate the ultimate erection of two power houses of 125,000 H.P. capacity each. Each power-house will be fed by a separate canal, and the water discharged by the turbines will be carried to the outlet through short tunnels of 200ft. and 800ft. in length respectively.

THE VALENCY OF MERCURY AND COPPER IN CERTAIN ELECTROLYTES.

The first part of a Paper, dealing with the valency of mercury in dilute solutions of the iodide, and incidentally describing a well-devised mercury voltameter, has lately been published by Dr. Werner Bolton in the *Zeitschrift für Electrochemie.* Such portions as appear of more than usual interest are here presented.

The point which the author desired to investigate was whether an undoubtedly *mercuric* salt, such as the red iodide HgI_2, was capable, when examined as an electrolyte in dilute solution, of behaving as a *mercurous* salt—that is, of becoming monovalent instead of divalent. The better to deal with this problem, a mercury voltameter was designed in order that comparison between the amount of metal deposited in the voltameter and that in the experimental cell might be made directly without the need for a connecting factor. The high electro-

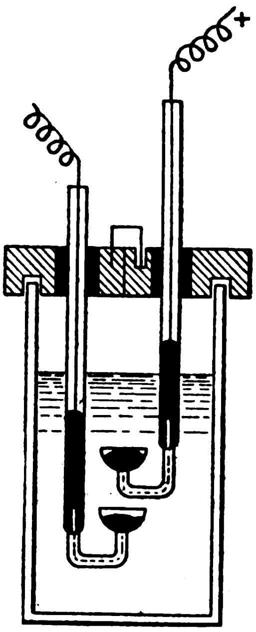

FIG. 1.

chemical equivalent (199·8) of mercurous mercury is an incidental advantage and a substantial additional reason for the employment of this particular metal.

In Fig. 1 is shown the form of voltameter adopted by the author. An ordinary beaker holding about 200 cubic cm. is provided with a well-fitting wooden cover, split for convenience of removal, and held together, when in position, by wire fastenings. The electrodes consist of mercury contained in cups blown at the end of the vertical glass tubes shown immersed in the liquid. Connection is made by means of a platinum wire, sealed into the horizontal portion of the electrode, with a column of mercury in the longer limb of the glass tube and thence to the source of current. The mercury in the cups is wholly distinct from that in the vertical column, and can be removed and weighed. The upper electrode is made the anode, so that risk of fouling the surface of the mercury by crystallisation of the strong solution of its salt flowing away from the anode is avoided. The electrolyte is a decinormal solution of mercurous nitrate, in which the whole of the mercury is monovalent. It is prepared by digesting a weighed quantity of the commercial salt with pure mercury and dilute nitric acid in a warm place for several days. No separation of basic salt need be feared when the preparation has been thus conducted. When the mercury in either cup is to be weighed it is dried by means of blotting paper as far as possible, and poured into a gutter of filter paper supported in a sloping glass tube with a draw-out end delivering into a weighing bottle, as shown in Fig. 2. Any globules of mercury sticking in the paper gutter are driven downwards to the bottle by judicious tapping.

With this instrument the loss of weight of the anode and gain of the cathode are equal in amount, and two such voltameters on the same circuit give substantially identical results, the maximum error being within that which may be properly termed experimental in a case of this kind, viz., 0·1 per cent. A table of observed values is given bearing out these statements. With a voltage of 3·74 volts, a slight evolution of gas from both electrodes was at first perceptible, but this soon disappeared and caused no alteration in the constant equality of increase and decrease of the weight of the cathode and anode. The range of the instrument is considerable, a small current operating for hours being valued as readily as a comparatively large current for a few minutes. No special precaution is requisite in removing the electrodes for weighing; on stopping the current the electrodes can be taken out at leisure, as they suffer no change in weight by mere immersion in the electrolyte. The mercury is carefully purified, so that about 1 cubic cm. of the metal can be evaporated in a porcelain dish without leaving a trace of fixed matter.

That portion of the research comprised in the present abstract is confined to the examination of the result of electrolysing aqueous solutions of mercuric iodide in potassium iodide. The solution of potassium iodide was in all cases of normal strength (166 grammes per litre). The quantities of mercuric iodide used were chosen so that the strongest solution corresponded with the formation of the salt K_2HgI_4 with the whole of the potassium iodide present. The remaining solutions were such that $\frac{1}{3}$rd, $\frac{1}{6}$th, $\frac{1}{12}$th, &c., up to $\frac{1}{384}$th of the potassium iodide could be considered as present in the form of the salt K_2HgI_4.

The figures obtained by performing an electrolysis with the mercury voltameter already described, and a similar cell containing as electrolyte one of the solutions defined above, in series, are given in the following table. In all cases the mean value from the + and − values of the two electrodes is taken.

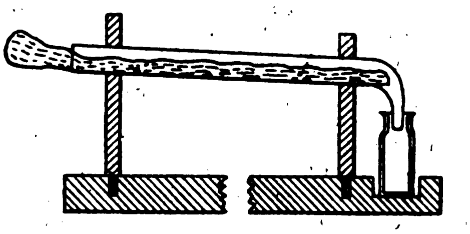

FIG. 2.

The figure thus obtained for the voltameter, in which the mercury is constantly monovalent, when compared with that given by the experimental cell, allows the valency of the mercury in the electrolyte of the latter to be at once deduced:—

Ratio of molecules of K I as K_2HgI_4 to total K I.	Weight of deposit.		Ratio of valencies.
	Voltameter.	Experimental cell.	
$\frac{1}{1}$	0·1425	0·0714	1 : 1·996
$\frac{1}{3}$	0·0812	0·0041*	1 : 1·980
$\frac{1}{6}$	0·2881	0·1435	1 : 2·007
$\frac{1}{12}$	0·1658	0·0824	1 : 2·012
$\frac{1}{24}$	0·3576	0·1788	1 : 2·000
$\frac{1}{48}$	0·4636	0·2411	1 : 1·923
$\frac{1}{96}$	0·1223	0·0685	1 : 1·786
$\frac{1}{192}$	0·1524	0·1026	1 : 1·486
$\frac{1}{384}$	0·2504	0·2172	1 : 1·153

From these figures it is evident that up to a dilution corresponding with a content of $\frac{1}{24}$th molecule of KI as K_2HgI_4 for each molecule of KI, only divalent ions are present; with a solution of half this concentration—viz., $\frac{1}{48}$th molecule—the ratio of the deposited metal in the two cells indicates that a portion of the mercury in the dilute electrolyte is present as monovalent ions, precisely as if mercurous iodide in place of the mercuric salt had been used. This change thus indicated becomes increasingly marked as the dilution is made greater. On plotting a curve from these results it is apparent that the solution may be expected to behave as if the whole of the mercury were in the mercurous state (*i.e.*, were monovalent)

* *Sic.* Probably should be 0·0410.

Digitized by Google

when a dilution corresponding with the presence of $\frac{1}{511}$th molecule of KI as K_2HgI_4 for each molecule of KI has been reached. This extrapolation is not justified by experiment, for when this dilution is approached, electrolysis ceases to go smoothly, and identity of the + and − values for cathode and anode no longer obtains. The result nearest to the theoretical limit was observed with a dilution of $\frac{1}{427}$th, when the ratio of valencies became 1:1·141. At great dilutions the scarcity of mercury ions causes the appearance of hydrogen instead of mercury at the cathode, while solution of mercury at the anode continues until the concentration of the electrolyte with respect to mercury is increased, and the balance between the deposition and solution is restored.

The author has also examined the polarisation and its distribution at anode and cathode of a cell containing HgI_2 in increasingly dilute solution, as in the previous series of experiments. He finds that the anode and cathode values are substantially identical, and that the total polarisation does not increase with the voltage employed up to a dilution of $\frac{1}{6}$th. At a dilution of $\frac{1}{12}$th, and beyond, the cathode value increases and that of the anode decreases, the difference becoming greater with an increase of voltage. This accords with a dictum due to Ostwald, who states that the polarisation of a metal in a solution of a salt of that metal increases as the concentration of the ions decreases, and that this holds in the presence of the ions of other metals, for each metal acts in all cases solely towards its own ions. The influence of concentration of ions upon polarisation may be conveniently stated thus: In the case of an electrolyte, in which is only a very small quantity of a salt of the metal composing the electrodes, it is evident that but few ions are in a state of migration. Suppose there be n ions at the anode, and the same number at the anode, and that of these r ions give up their charge at the cathode, and that a like number are contributed by the anode to the electrolyte. Then we have at the cathode $n-r$ ions and at the anode $n+r$ ions. Seeing that n is small in this particular case, and that r is constant for all concentrations, the latter in a highly dilute solution will be but little smaller than n, so that the fraction $\frac{n+r}{n-r}$ is comparatively large, *i.e.*, the number of the available ions at the anode will be considerably greater than that of those at the cathode, and their polarisation values will be correspondingly different. When r is small relatively to n the values of anode and cathode become approximately equal. This, as stated above, was observed to hold good up to a dilution corresponding with the presence of one-sixth of the total molecules of KI in the form of K_2HgI_4.

REVIEWS.

Electrical Influence Machines. By JOHN GRAY, B.Sc. (Whittaker and Co.)

Mr. Gray's work on influence machines is an honest attempt to bring this subject into line with modern ideas. He starts off with elementary notions about the electric field and the properties of dielectrics, and adopting the Maxwell-Lodge device of representing the action of displacement in the dielectric by elastic displacements in "cells," proceeds to discuss on this basis electrostatic forces, and the tendency of points to discharge. Then follows a useful but somewhat irrelevant chapter on electrometers (chiefly the quadrant), ending with a description and picture of one of Lord Kelvin's graded potential galvanometers. The latter is apparently recommended as suitable to measure the currents given by influence machines. We then enter upon the main part of Mr. Gray's book. Beginning with the electrophorus, we are led on by the historical path of development, from Bennet's doubler and Nicholson's revolving doubler to the more perfect machines of Belli, dating from 1831, which were unearthed by Prof. Silvanus Thompson in 1888. We then come to the modern epoch of Varley, Kelvin, Toepler and Holtz, the machines of the last-named being described in considerable detail, extending over 40 pages. The Holtz machine "of the second kind," which is described on pp. 141 to 143, is of interest as being a crude forerunner of the modern Wimshurst type, with oppositely-rotating plates. The suggestion, on p. 147, to prevent "reversals" in this machine by using a diagonal conductor curiously resembles one made lately by Schaffers in the *Annales de Chimie.* Mr. Gray then describes the Wimshurst machine, giving some account of its early history. The date of its first appearance is given as 1883. There seems to be some error here, as it was certainly publicly described and shown in the spring of 1882. Various subsequent forms are described, including the great 7ft. machine at South Kensington. At this point Mr. Gray returns to Lord Kelvin's water-dropping collector, and to the replenisher, winding up this part with an abstract of Maxwell's theory of a "regenerator" for the machine. The third and last part of the book is all too short. It describes in detail, with dimensioned sketches, the construction of Wimshurst's machines in a manner entirely admirable, even dealing with such matters as the proper mode of cutting glass discs. Incidentally, we are recommended as the best cement that used for bicycle tyres. The general notes on construction and use of Wimshurst machines, on p. 222, are excellent. Mr. Gray has not hesitated to borrow from those who have written before him on this topic; but he does so with honourable acknowledgment of his indebtedness.

The Wimshurst Electrical Influence Machine: its Construction, Theory of Working, and Experiments that can be performed with its aid. By WILLIAM PHILLIPS MENDHAM. (King, Mendham and Co., Bristol.)

Mr. Mendham's handy and unpretending manual goes straight to a general description of the ordinary forms of Wimshurst's machines, with two and with multiple plates. A short section on pages 19-23 is devoted to a simple non-mathematical exposition of the theory of the machine. Then comes a section on Leyden jar experiments, followed by a chapter in six pages on electrometers, in which the utterly antiquated balance of Coulomb overshadows all the modern electrometers. The best part of the pamphlet is the last chapter, entitled "Experiments with the Wimshurst Machine"; for, though many are familiar by age, they are redeemed by such modern additions as Lodge's notable experiment on the deposition of dust and smoke.

OBSERVATIONS ON THE HOLTZ THEORY OF INFLUENCE MACHINES WITH OPPOSITELY ROTATING DISCS.

BY JAMES WIMSHURST.

All physicists must be interested in the Paper recently published by Prof. Holtz, which contains his views of a theory for influence machines which have oppositely rotating plates. He has done good work in the cause, and his view commands respect, but his strictures directed towards others who also have done good work are less liberal than might have been expected.

It must, I think, be freely admitted that no one at present knows definitely the character of electricity, nor do we yet know the whole of its behaviour. Moreover, we daily see experiments which may be used either to support or to condemn a theory; nevertheless, it is always desirable to work upon some hypothesis. For my own part I frankly confess I have not been able to accept any theory which has been advanced as conclusive or true.

Prof. Holtz, in common with many others, appears to treat of the subject from the view of an existence of two electricities. No one can say he is wrong; but this view tends rather to complicate than to explain matters. It is very much more simple, and I think nearer the truth, to approach the subject from the standpoint of there being but one electricity existing, and afterwards to deal with an excess on the one hand and a deficiency on the other hand, which are commonly referred to by the terms positive and negative, supplementing this by

Digitized by Google

the further view that all dielectrics behave as though they carry a normal charge upon them, distributed uniformly over their surfaces, forming, so to speak, an elastic film, the one side of which acts in harmony with the other side. As an example of this, let us suppose the usual vertical plate of glass upon the table, and that we are about to show the effects of induction; let us suppose that the plate is coated on both sides with an electrical film; let a positive charge be brought near to the one side; the film on that side is then pressed in by the positive charge, and the film on the far side is pressed out. If the positive charge be withdrawn, the vertical plate again becomes normal. Then let us again present the exciting positive charge, and at the same time touch the plate on the far side, so as to allow of the induced positive charge escaping; upon the removal of the exciting charge it will be found that both sides of the plate are negatively charged. To produce equilibrium, the positive charge which was allowed to escape from the far side of the plate must be replaced; in other words, a positive or excess charge induces another positive or excess charge, and it is only by a supplemental act—that is, the permitting of this induced positive charge to escape—that a deficiency or negative charge is obtained.

Applying this hypothesis to the transference of the charges common to all influence machines, commencing with Wilkie in 1762, Volta in 1775, Bennet in 1786, Cavallo in 1787, and the first influence machine having revolving carriers, that by Nicholson in 1788, up to the Carré, the Varley, the Holtz, and the Voss of recent years, I could not resist the conclusion, after observing the behaviour of these machines, that the fixed inductor plates were conducive of a considerable amount of waste, and that better results would be obtained by making both plates active, and that this might be done by rotating the plates or surfaces in opposite directions. With this thought I constructed a machine having an endless band of gutta-percha, extended by two rollers, using other intermediate rollers to hold the surfaces near to one another; these intermediate rollers answered also as brushes or contacts. The instrument worked, and gave fair results. Following this, I designed the type in which there are two oppositely rotating plates, and so little doubt had I of its behaviour that I spun the glasses round with my fingers as soon as they were mounted and the brushes in place; the excitement was immediate. My next endeavour was to so construct a machine, suitable for lecture purposes—that is to say, one which would work in almost any condition of atmosphere—that it should furnish a constant flow or current for outside use, and that the direction of this flow should not change, all previous machines being subjects of that objectionable defect. Metal sectors were used only to act as reservoirs, and to deliver by metallic contact the small charges gathered from a large area. The combs and the terminals were added in order to preserve a circuit for use outside the machine, and certainly not for the purpose of adding to the excitement, but when properly placed they are objectionable only in a very slight degree, for if they were not present the high charges would escape either into the air or would travel over the surface of the plates to the nearest brushes.

It was some time after I had done all this that I showed a machine so completed to a scientific and literary friend. He was charmed with it, and, like other literary men, began to search and find what others had done. This led him a few days later to bring me a picture of the second form of Holtz machine, which consists of two plates rotating oppositely in a horizontal plane, the axis being vertical. Each plate had two combs to the upper plate and two combs to the lower plate, situated at right angles to each other. The machine was not self-exciting, and of course when the circuit between the combs was broken to any distance the excitement practically ceased.

This was the nearest type of instrument which could be found, and I endeavoured to find some Continental maker from whom I could obtain one; but up to the present day I have been unable either to find such a machine or to hear of any person who had seen one of them. Prof. Holtz may therefore accept my word of honour that I did not know a single feature of his second machine until after mine had been at work for some time, and he may well believe that the details which he condemns were not added in the mistaken idea that they contributed to an increase of the charges—they are simply additions, made in the least objectionable manner, in order to produce a useful and reliable instrument.

In respect to the electrical changes which take place in these machines when fully excited, I would refer to the diagram, in which the plates or discs are represented as cylinders, and that the changes may be more apparent, I assume the machine to be fully excited. The relative values of the charges at the several parts are indicated by numbers, which are intended to indicate only a rising or a falling of the charge, and have no quantitative value. The plates rotate in the direction shown by the arrows, and the brushes are shown by A B C D. The front plate passes away from the brush A, moving to the right with a small − charge, followed by neutrality, then a small + charge; but as soon as it reaches a point opposite the brush C the charge increases rapidly, almost to its maximum. This is owing to the considerable transference of electricity from the inner surface of the back plate to the inner surface of the front plate. The maximum charge is reached at about the horizontal line; this condition holds good for a short distance further, when it begins to diminish owing to leakage towards the brush B. At this brush the charge almost vanishes, but a small portion of the charge remains after contact with the brush, then

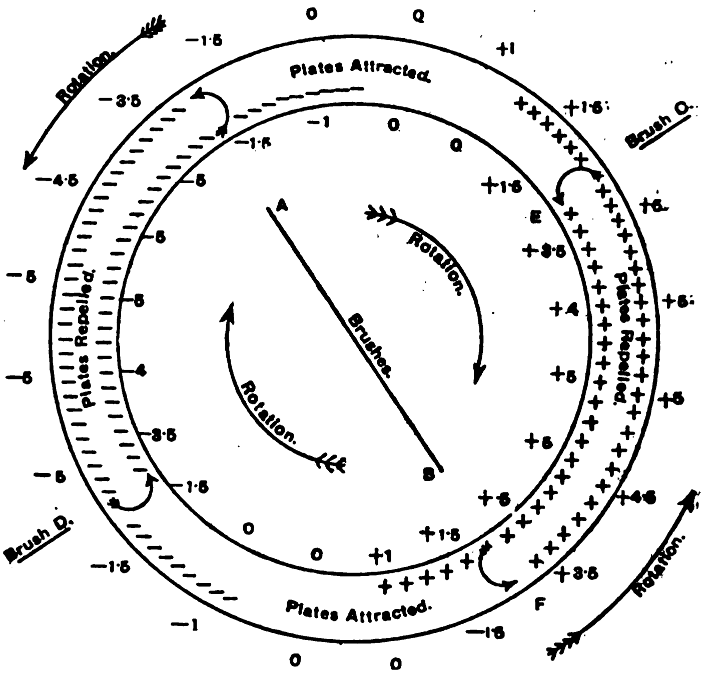

Diagram illustrating the Distribution of Charge in a Wimshurst Machine.

comes neutrality, the second half of the plate follows in the same order. The charges on the back plate follow in a similar manner to those on the front plate, but the rotation of which, it must be remembered, is in the opposite direction.

We may now consider the changes which take place between the plates, and it is here the real work is done. Let us commence at the point marked E, bearing in mind the hypothetical elastic electrical film. This film on the outer surface of the back plate is pressed in by the brush C (or the excess of electricity is removed by this brush), the effect of which is to release a considerable charge from the inner surface of the back plate, and this released charge is transferred to the inner surface of the front plate, as shown by the curved arrows. It is this continuous transfer of electricity to the inner surfaces of the plates opposite to the brushes, and its carriage back to the horizontal diameter by the plates, that increases or adds to the excitation, for it must be remembered that these carried charges on the right of the diagram are all +, and all on the left side are −. They being of the same sign, they naturally repel each other; the energy put into the machine, however, thrusts them together and produces the large charges of free electricity of a like sign upon the outer surfaces of the plates.

Digitized by Google

Let us now see what takes place at the top and the bottom portions of the plates. Commencing at the brush B, a part of the + charge escapes the brush, and is carried to the left. A like + charge is also carried on upon the inner surface of the plate, while at the brush D a − charge escapes and is carried by the back plate to the right; the inner surface of this plate also has its charge of −. These charges on both surfaces of both plates are − on the left hand and + on the right hand; the motion of the plates brings these charges of opposite sign together, and at about the vertical line neutrality of all four surfaces is produced. These actions are rendered very apparent by using flexible discs which forcibly repel one another in the horizontal line and as strongly attract one another in the vertical position. I exhibited this action at the Royal Institution in 1888.

All these changes have been many times tested by me on machines varying in diameter from 2in. to 7ft. The most useful size, perhaps, is a machine having plates of 3ft. 6in. diameter, and made so that the plates may be set any distance apart within certain limits. When set at 3in. apart and with suitable analysers, all these changes may be beautifully seen in a darkened room. Another feature is that when such plates are separated one-twelfth of their diameter they are capable of just producing visible excitement, but not sufficiently to give a spark. When, however, a fairly large initial charge is given to the combs on one side of the machine, the excitement increases, and the machine will give one spark of the maximum length, and the excitement again falls to be only just appreciable.

With regard to the sectors, they are necessary evils, and the less of them the better. I have obtained very good results from 16 strips of tinfoil $\frac{1}{16}$in. broad upon each plate, but the more metal the more reliable is the machine in damp atmospheric conditions.

I am afraid that I am trespassing too far upon your space, so I will end my remarks by suggesting that no person benefits from undervaluing the work done by others. It must be remembered that influence machines are now more than a century old, yet we appear to know little about them which can be accepted as reliable. Every worker therefore should be encouraged. I have given years of time and hundreds of pounds in perfecting and introducing a sound, useful type with no other reward than to see it adopted and valued; and while I cannot disagree with Prof. Holtz in the statement that there is nothing wonderful or special in a self-exciting influence machine, still, if that truism were the only compliment or reward a worker had to look forward to I rather fear that anything like painstaking trials and improvements would speedily be ended.

THEORY OF THE INFLUENCE MACHINE WITH OPPOSITELY ROTATING DISCS.*

BY W. HOLTZ.

I have up to the present not felt called upon to give a complete account of the theory of the influence machine with oppositely rotating discs, since for a long time only a few physicists were in possession of such a machine, and it would only be of interest to them. In the last few years the case has been altered; the machine is coming more into use, especially abroad, where latterly several modifications have been introduced. But it is just the character of these modifications which shows me that the theory is as yet little understood, since quite secondary details are apparently considered as essential, and their introduction is supposed to amount to new discoveries. I should therefore like to set forth this theory pretty completely, and to point out the various forms which may be given to the machine.

The Fundamental Principle of Excitation.

Let two endless strips of an insulating substance continuously pass, the one to the right, the other to left (Fig. 1). Let a comb be placed in front on the left and at the back on the right, the points being directed towards the strips. Let the combs be connected with each other, so that the connection may be easily broken somewhere. Let a negatively electrified body be placed momentarily opposite the comb a behind the strip. The influence effect of the electrified body causes the two combined electricities of the face of the front strip to be separated. The similar negative electricity flows into the comb, while the positive proceeds with the strip. Through the influence of the latter change the electricities of the back strip are separated, the similar positive electricity flowing into the comb, and the negative passing on with the strip. Since, therefore, negative electricity arrives opposite the comb a, it looks as if the electrified body was no longer necessary for the continuance of the process. But this is only conditionally true. Each strip charges the other, but not necessarily to a greater density, and eventually to a less density than it was charged itself. If each new charge is less dense, the electromotive activity must soon be lost after the exciter is removed. The induced charge will only support itself when it is denser, and then it will not only support but increase itself, and that will continue until the losses, which increase with an increasing density of charge, do not permit a further intensification.

On introducing a gap into the connection of the combs, the displacement of electricity, and hence also the charging of the strips, is impeded. If the electromotive activity was kept up before, it may now be lost after introducing the gap. In any case this will happen on continually increasing the gap, as soon as the electricity can no longer pass across it.

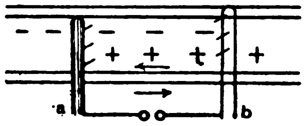

FIG. 1.

The Various Forms of the Machine.

Two discs may be regarded as two endless strips, and the principle enumerated may be applied to them in various ways, so that the same machine, constructed on the same fundamental principle, may have different forms. Fig. 2 shows the simplest construction, with two combs, a and b, which only serve for the charging of the discs, and a double comb, c, which only discharges the discs and makes them return unelectrified. Let the exciter always be negative, and placed opposite the comb a. Then the + and − signs indicate the actual electrical condition of the discs. That the signs for the front disc lie on a larger circle, and those for the back disc on a smaller one, must not be interpreted as meaning that each disc is only electrified in such a circle. This first form of the machine is very feeble as regards quantity, since it is evidently only the charge current which flows through the electrodes; and

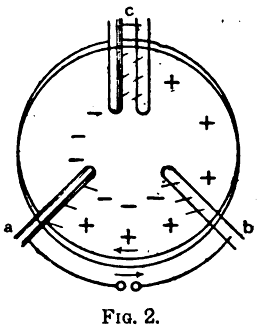

FIG. 2.

it is also feeble as regards intensity, since the electrodes cannot be much separated without stopping the action of the machine. This form was also given in my first work.*

Fig. 3 is produced by substituting two double combs for the one, and introducing the spark gap between these, while the two charging combs remain constantly connected. This form acts quantitatively like the first, since the discharge current is always quantitatively equal to the charge current; but it gives much longer sparks, since the electrodes may be separated to any extent without stopping the actions. If instead of the two double combs there is one, the effect is essentially the same, but it is unsymmetrical, since the density at one of the poles is always greater than at the other. In this form, and with one of the poles to earth, I mentioned this type in my first Paper (p. 135), and in an addendum on p. 169 I pointed out the advantage of having a second double comb. A drawing like Fig. 3 was produced in a later Paper of mine.

Fig. 4 shows the machine provided with four simple combs, arranged so that they are alternately on different sides of the discs, in which case it is indifferent whether the electrodes lie between c and d or between a and b. This form is practically simpler, but theoretically more complicated, since each comb has here to effect

* *Wied. Ann.*, No. 1, 1895.

* *Pogg. Ann.*, 130, p. 134, 1867.

Digitized by Google

a discharge and also a new charge. Thus the comb *a* takes its negative electricity from the front disc, but receives more negative electricity from the same disc through the influence of the back disc; the front disc becomes positively electrified, so that the comb discharges the disc and gives it a new charge. The same thing happens with the other combs. Hence a double current, so to speak, now flows through the connecting wires, the charge current and the discharge current, and this form will therefore act twice as strongly as the first two. The intensity is also slightly higher than in the first case. For if with an increasing spark gap between *c* and *d* the charge current ceases, the machine continues to work according to the plan sketched in Fig. 3, though with lessened quantity. But if the discharge current also momentarily ceases, its activity is at once impaired, since the wrong electricities now approach the combs *a* and *b*.

If the connection *a b* is omitted, but *a* is joined to *c* and *b* to *d*, we obtain Fig. 5. For it is evidently indifferent whether the electrodes remain between *c* and *d* or are introduced between *a* and *b*, as in Fig. 5. The electric condition of the discs is exactly the same as in Fig. 4, where the combs *a* and *c* become similarly electrified, and also the combs *b* and *d*. Into the first, negative

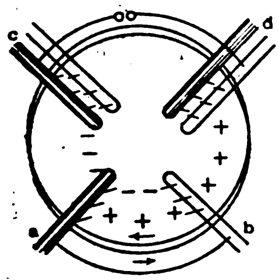

Fig. 3.

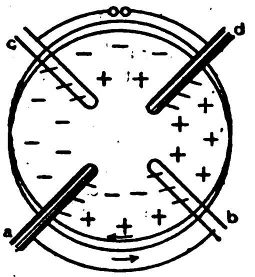

Fig. 4.

electricity is conducted from two sources; into the latter, positive electricity in the same manner. With this connection, then, the machine must act quantitatively twice as strongly as the former, and four times as strongly as the first form. But as regards intensity, it must act like the first form, since with the cessation of the charge current its activity must cease. This form I particularly emphasised in my first work, but I added that its external effect sometimes ceased unless a double comb were substituted for the single one, for the reason appended on p. 169, viz., because otherwise the discs sometimes divide up into two oppositely electrified zones. I shall not develop this any further here, but will only add that the Fig. 4 type, probably owing to the same cause, sometimes loses its external effect.

Fig. 6 is developed from Fig. 4 by connecting the combs *a* and *d* and also the combs *b* and *c*, and having them made up of one piece. Such double combs of straight or curved rods, placed across

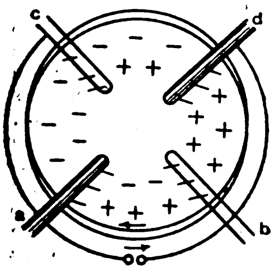

Fig 5.

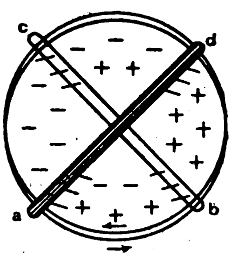

Fig. 6.

the centre of the disc, have been called diametral conductors. Each comb acts as in Fig. 4, *i.e.*, it serves simultaneously for the charging and discharging of the discs, except that the double currents, which formerly flowed through the bent wires, must here run through the diametral conductors. The form as it is does not, of course, give any external effects, however active it may be internally, since the circuit remains closed. I only enumerate it as a transition form to the next, which thereby becomes more intelligible.

Fig. 7 is at once obtained from Fig. 6 by adding the combs *e* and *f* connected with the electrodes. The action of these combs may be understood from the following considerations. Fig. 6 shows that between *a* and *c* both discs are negatively and between *b* and *d* positively electrified, and also shows that the withdrawal of these electricities cannot destroy the activity of the machine. For the comb *a* will charge the other disc positively as before, since the back disc when approaching is still negative, and the comb *b* will charge the back disc negatively as before, since the front disc when approaching is still positively electrified. The same applies to the combs *b*, *c*, and *d*.

Another question is whether the new combs, which only approach the front of the disc, can also discharge the back of it. As far as external effect goes, they do this, at least in the main, since they take up more electricity than the front is charged with, just as a rubbed ebonite plate loses its charge by a one-sided comb. Regarded in this way, Fig. 7 also represents the electric condition at the part of the plates in question. In reality the case is slightly different. The front disc loses by the influence effect of the other more than its own charge, so that when it leaves the comb it is not unelectrified, but oppositely charged. If, however, the external effect were as if both discs were discharged, a double comb, as was once recommended by Musæus, would be unable to increase it. A different case would be presented by two connected combs displaced relatively in the direction of rotation, as Musæus also recommended, and has recently been again proposed by Schaffers.*

Let us next consider the form shown in the figure, which I published as early as 1869.† It is evident that as regards quantity it must yield about the same as Fig. 4. But, as for intensity, it

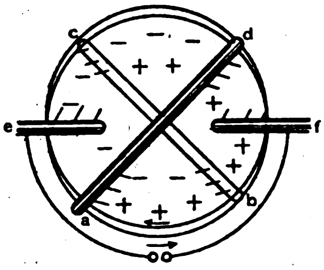

Fig. 7.

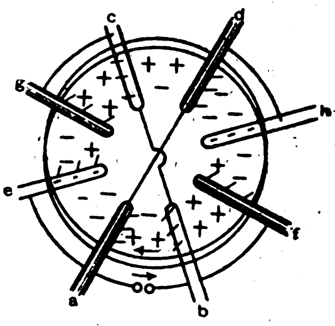

Fig. 8.

must yield more; as much, in fact, as Fig. 3, since in both cases the activity of the machine is quite independent of the position of the electrodes. But if, according to Musæus' plan, the combs *e* and *f* are replaced by two pairs of combs, as in Fig. 5, the machine may indeed yield the same in quantity as Fig. 5, but must lose considerably in intensity.

Fig. 8 shows a form with two combs, each of which acts simultaneously for charging and discharging, the combs being connected so that the total quantity of electricity generated flows through the electrodes. For into the combs *a*, *e*, *d* and *h* negative electricity flows from two sources, and into the combs *b*, *f*, *g*, and *c* positive electricity from two sources. Connection is established by two diametral wires, one of which has a bend in the middle. This form must give eight times the quantity of Fig. 2, or four times that of Fig. 4 or Fig. 7. But as regards intensity, it yields less than Fig. 2, and its activity ceases with the cessation of the discharge

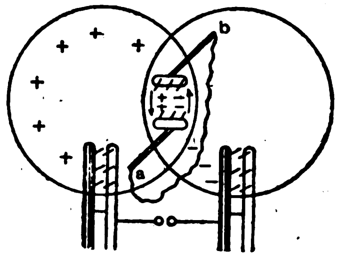

Fig. 9.

current. It has the further drawback that sometimes the torrent of sparks suddenly ceases, owing to the above-mentioned formation of zones. This form was also described in *Uppenborn's Centralblatt*, p. 684, 1883.

Finally, Fig. 9 shows an arrangement in which the discs only half cover each other. Opposite the superposed portions are two combs, which only serve for the charging of the discs; whilst in the places where they do not overlap, a double comb is placed for the discharge of each disc. The electrodes are placed between these combs. It might be thought that the discs would be sufficiently discharged by one simple comb each. This would be the case if their external surfaces only were electrified. But the inner faces are also electrified, since the round edge of the one acts, so to speak, as a comb towards the other. Hence its effect is considerably less than that of Fig. 3, although theoretically the similarity is very great. I cursorily mentioned such a machine in my first Paper (p. 137).

The Fundamental Principle of the Process of Intensification.

I said that the electromotive activity was maintained only if each new charge was stronger than the last. But it may further be asked, Under what conditions is this assumption true? I have already developed at length the chief condition or fundamental principle of the intensifying process in my first Paper, not only for uncovered discs, but also for such as are provided with narrow strips of tinfoil at right angles to the direction of motion. If opposite the charged plate of a condenser we put a plate of equal size and touch it with the finger, the density of the charge thus produced will doubtless be smaller than that of the first. But if we place a small sphere in the neighbourhood of the first plate and put it to earth in the same way, the density of its charge will very probably be greater than the density of the first. In general, when a charged surface influences another of equal size, and so that it must be charged all at once, the density of the new charge will invariably be smaller than the density of the first. But when it influences another and a smaller one, or when it is so arranged that the second surface can only be charged gradually in separate parts, the density of the new charge will generally be greater than that of the first charge. In our influence machine we have the latter case. Here the influence proceeds from larger surfaces upon surfaces which can only gradually assume a charge, *i.e.*, only in the radius which momentarily passes the points of the comb. But in most forms of the machine there is another intensifying influence at work.

It will be seen from Fig. 10 that the front strip is negatively electrified when opposite the comb *a*. In the absence of this negative charge, the new charge would, by the previous reasoning, probably be already denser than the charge of the back strip. But that negative charge also favours this result by drawing, from a distance, positive electricity on to the surface of the strip, and more than is necessary for the instantaneous neutralisation of the portion under the comb. That is also the reason why the plate of a frictional machine is not unchanged when leaving the earthed comb, but is negatively electrified, as anybody may prove by trial. I formerly called this effect "side attraction." Riess afterwards called it "influence of an electrified surface upon itself."

But when, in spite of all, the desired effect is not always obtained, this is due to other opposing factors. Thus, the discs may not always be sufficiently insulating in a circular direction for this is what we are dealing with), and this may be due to the material of the plates, or to the fact that the humidity of the air makes them conducting. Further, the plates are often not as close together as they might be, or the combs are not close enough to them; or the combs have too few points, or the latter are not fine enough. The last case impedes the transference of electricity and thus contributes to the diminution of the charge. Eventually the latter will be so great that feeble charges no longer pass. Then the desired effect only takes place with stronger charges of the exciter. If the resistance to transference is altogether absent, the intensifying process takes place all the sooner, and the feeblest electric influence will start it. This is attained by covering the discs with radial strips of tinfoil, and using contact brushes instead of combs, or better, by retaining the combs and attaching to each a little brush which touches the disc. I published this as early as 1881,* and I recall this now because two years later Wimshurst† described a machine thus arranged as his own invention. But the metallic armatures referred to have the disadvantage of favouring dissipation, and thus enfeebling the effect of the machine in quantity and intensity. They also favour a change of polarity, which is due to the fact that the inner faces of the discs also become electrified and work with this charge when the outer surfaces momentarily lose their charges. They also impair the transparency of the machine, and thus intercept the luminous phenomena which otherwise are such a valuable aid to the study of the theory.

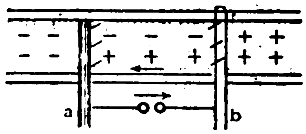

FIG. 10.

The Self-Exciting Process.

The metal strips on the discs and the contact brushes make the machine self-exciting. The reason for this is that a feeble impulse will now start the intensifying process, and that this impulse is given by the frictional electricity itself. The contact brushes touch the insulating surfaces at intervals, so that some assume positive and others negative charges, and there will never be a perfect balance between the charges thus produced in different portions of the plate. Hence a self-exciting machine is nothing wonderful or special, and its theory is none other than the theory of the ordinary machine. It is more convenient, of course, but it has all the drawbacks of machines with metal-covered plates.

ON THE THEORY OF THE WIMSHURST MACHINE.*

BY V. SCHAFFERS, S.J.

The attempts which have been made up to now to explain the action of the Wimshurst machine have related mainly to the way in which a charge produced at a given point spreads over the plates. The normal action when the machine has once been charged has been deemed to be sufficiently explained by assuming that the combs discharge the sectors. As a matter of fact the quadrants embraced by the combs are of the same sign, and their charges ought consequently to repel one another. The plates are therefore supposed to be neutral from the combs to the next brush in the direction of rotation. Now it is this very part of the theory which is the most imperfect and the least in conformity with experience. In reality the plates are not neutral at any point, and we shall see that the part played by the combs must then be very different to that actually assigned to them. At the same time it may quite well be admitted that in a perfectly symmetrical machine the action may be that assumed by existing theories, though, as we shall see, it is a very special case.

Let us draw a diagram of the machine according to M. Bertin's classic plan, in which the cylindrical sections B B′ and D D′ represent the two plates. Let us assume, first of all, that we start the machine after having removed the combs; the distribution of

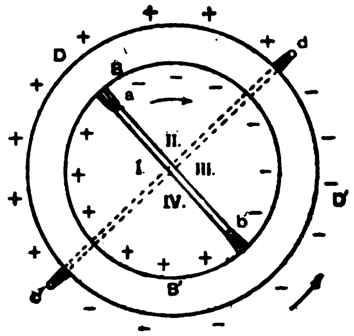

FIG. 1.

charge will be represented by Fig. 1, the quadrants I. and III. being of the same sign on both plates, whilst the quadrants II. and IV. are of opposite sign. If we walk up to the machine in the dark, comb in hand, it will be seen to give discharges in front of quadrants I. and III., but not in front of II. and IV., for the charges induced on the combs by these quadrants neutralise each other. Let us now replace the horse-shoe shaped combs, and approach the moving points. We shall no longer obtain, as before, discharges all over quadrants I. and III., but only in one half; for instance, between E and *a* and between H and *b* (Fig. 2). Thus, between E and *c* and H and *d* the plates are of opposite sign, like the quadrants II. and IV. This fact is evidently incompatible with the theory which assumes that the combs only serve to discharge the plates, for in that case the phenomena ought to be the same on both sides of the combs, the first plate being neutral between E *a* and H *b*, and the second between E′ *c* and H′ *d* (Fig. 3). The observed lack of symmetry can only be explained on the assumption that the combs have only acted on one of the plates, on D D′, for instance, in the present case (Fig. 2); and, secondly, that they have not merely neutralised the sectors, but have communicated a charge of opposite sign to them, the conductors *c d* remaining inert. Conversely, in the case of the plate B B′ it is the conductor *a b* which alone acts to change the sign, and the combs E H do no work. The action is thus the same as when the machine has no combs, with the single exception that one pair of combs plays the part of one of the diametral conductors.

In order to better investigate these phenomena I made use of a machine which had no U-shaped combs, but in place thereof separate pairs of combs. Each pair of combs was connected to a distinct pair of electrodes. With the exciter closed this apparatus works like any other; but if the electrodes are only separated on one side no sparks are obtained, and one observes in the dark that the separation of the electricities then takes place on the side of the open exciter at the diametral conductor, and on the other at the combs. With the two pairs of electrodes open sparks only

* From the *Annales de Chimie et de Physique*, May, 1895.

Digitized by Google

pass between the two balls nearest each other; the others once again are replaced in action by the diametral conductor facing the same plate. As a rule, therefore, the machine only makes use of half its brushes and combs, and the active combs are those which form part of the circuit in which the movement of the electricity is the easiest.

On the ordinary machine the same phenomenon takes place. The combs do not act to the same degree on the two plates, although connected to the same circuit. Even a minute difference in their distances from the surfaces of the glass, or some other lack of symmetry in the apparatus, always causes the action of one of the two halves to predominate, and instantly the diametral conductor on the opposite side becomes active and takes the place of the other half of the comb in the working of the machine. One-half of the horse-shoe combs is, therefore, useless and even detrimental; for one may make sure in the dark that it gives a feeble flux of the

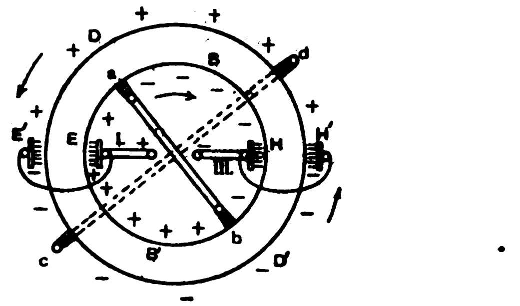

Fig 2.

same kind as active diametral conductor on the same side. *Straight combs should therefore be used.** For the same reason the diametral conductor on the same side as the active comb is somewhat detrimental to the efficacy of the machine. It is, however, indispensable to prevent reversal, and it suffices for this, although there are two moving plates. There is, in fact, a closed conductor on the second plate in which reversal can consequently never occur spontaneously; consequently only one diametral conductor is required, and that in front of the plate before which the combs are placed.

The most rational form of the Wimshurst machine would thus be provided with the two existing diametral conductors, and two straight combs facing the same plate instead of the horse-shoe combs. The best results will be obtained when the diametral conductors are 60deg. apart and 60deg. from the combs, and not at right angles to each other, and 45deg. from the combs as at present. This follows from the evidence brought forward as to the part played by the diametral conductors. In ordinary working the active combs must be as far as possible from the active conductor,

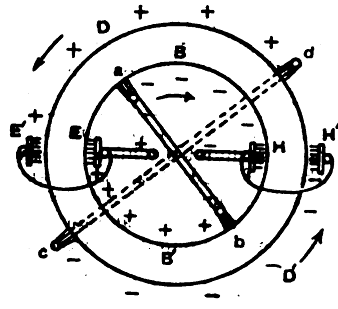

Fig. 3.

and in case of tendency to reverse, the two conductors must be as far as possible from each other in order not to interfere with each other.

Let me add one observation for the benefit of those who wish to repeat this investigation. The phenomena I have just described are only easily observed on the machine with separated combs. When the combs are joined, or when an ordinary machine is used, the appearances are somewhat different, but they in no way invalidate the interpretation just given.

I have stated that the active circuits are always those in which the movement of the electricity is the most easy. Now, the diametral conductors are usually keyed directly on to the iron spindle of the apparatus, and this spindle does not offer a sufficient resistance to prevent easy communication between the two conductors. In many machines—and this was the case with the two machines of which I had the disposal—it thus happens that the easiest circuit is that of the two halves of the diametral conductor united by the spindle, combined with that of the two combs placed the one in front of the first plate and the other in front of the second. In this way, for example, the distribution shown in Fig. 4 is obtained. The changes of sign take place at E′, *a*, *d* and H, as is easily seen in the dark.

All that has been said assumes the electrodes to be closed (or at any rate one pair when there are two). With the electrodes open the two circuits which perform the function of diametral conductors (two combs and one conductor) also become active and give a flux of the same sign as that of the neighbouring parts. Then all the combs and all the brushes situated on the left of the vertical diameter of symmetry of the machine have, let us say, a positive charge, all those on the right a negative charge. These phenomena fall in perfectly in my explanation, since the precise object of diametral conductors is to supplement the action of the combs when the resistance of that circuit is too great by reason of the opening of the exciter.

To check all these conclusions I removed the combs and the conductors which I found to be useless. The nature of the flux in the remaining parts was in no way altered. Further, I compared the output of the machine in the three following ways:—First I joined the combs so as to have an ordinary Wimshurst machine, then I suppressed the combs in front of one of the plates, whilst leaving the two diametral conductors in their places; lastly, I removed the combs in front of one of the plates and the diametral conductor in front of the opposite plate. The following are the figures obtained

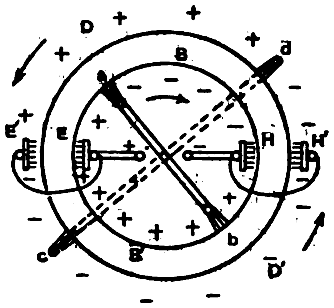

Fig. 4.

in one of my series of experiments, *n* being the number of revolutions per minute of the machine handle and *e* the number of sparks in the same time to the Lane bottle:—

	n	*e*		*n*	*e*		*n*	*e*
First arrangement.	43 44	132 140	Second arrangement.	45 43 41	137 131 129	Third arrangement.	45 47 49 47	145 151 152 147

These results, it is true, have no very precise value, owing to the impossibility with the apparatus at my disposal of maintaining a constant speed, of preventing the slipping of the belts, and, finally, of counting fractions of turns. Nevertheless, they clearly show that the quantity of electricity set in motion at equal speeds is sensibly the same in all three arrangements.

The new theory is therefore in perfect agreement in experiment. It leads, further, to a very important consequence, which it is easy to verify, and which points to a genuine improvement to be made.* According to my view, there is in every Wimshurst machine a closed diametral conductor (or two halves of a conductor connected by the spindle) in which all the movements of the charges of the corresponding plate take place. It is obvious that all the electricity thus developed is lost, so far as the useful output of the machine is concerned, since the conductor does not communicate with the electrodes. If we cut this conductor, and put it into connection with them, we ought to obtain twice the output of the ordinary machine,† with the exception, perhaps, of a certain reduction due to the fact that the induction would be less easy. Experiment shows these expectations to be quite correct. The machine, however, very easily reverses for somewhat long sparking distances. This is to be expected, since, after all, all that has been done has been to accurately reproduce the arrangements of a Holtz machine of the second order, which, as everyone knows, very easily reverses. This reversal may be prevented by means of two diametral conductors; one will not suffice, since the reversal may take place on either of the two plates.

* *Comptes Rendus*, Vol. CXIX., page 536, September 24, 1894.

* *Comptes Rendus*, Vol. CXIX., p. 536.

† If we assume that the U-shaped combs (*peignes à machoires*) have no other function except that of discharging the plates, as was formerly assumed (and, as I have already said, that explanation is plausible in the case of an absolutely symmetrical machine), the same conclusion is arrived at; in fact, if the combs, after having neutralised the glass, themselves recharge it, it is clear that they would give out twice as much electricity.

Digitized by Google

In Fig. 5 is shown the arrangement I have finally adopted. The plates are the same as in the ordinary Wimshurst machine. At the end of a horizontal diameter, in front of one of the plates, are two insulated combs, E′ and H′, somewhat longer than the sectors of the plates, and provided with a brush which rubs against the knobs of the sectors. In front of the other plate, along a diameter making an angle of about 60deg. with the horizontal, are two similar combs, E and H, each of which is connected with the nearest comb of the first plate, and each pair thus formed is connected with one of the electrodes. The plates should be made to revolve in such a direction that before reaching the comb which discharges them they pass in front of the other comb connected to the same electrode. In that case the two combs of each electrode give the same electricity, and the knob is charged with the contrary sign; in the other case the two combs would give opposite fluxes and the knobs would remain neutral. This mode of working is absolutely identical with that of the second Holtz machine.

The chief difficulty was to find a suitable arrangement of diametral conductors. On investigating the action of these parts in single-plate machines, it is seen that they ought to be placed a little beyond the combs in the direction of rotation, and secondly, under the influence of the inductor which acts on the same comb. Let us apply this principle to each of our two plates. The diametral conductors must not first of all be within the quadrants included by the combined combs. In the other quadrants they would replace in the working of the machine a set of combs on one of the plates, or even both, and the useful output would be diminished or extinguished. To fulfil the second condition let me point out that here the inductors are the charges on the plates and that the demarcation of these charges when reversal tends to occur is displaced towards the diametral conductor. Let us consider the conductor *a b*, which should supplement the action of the combs E H in case the sparking distance is too great. The conductor

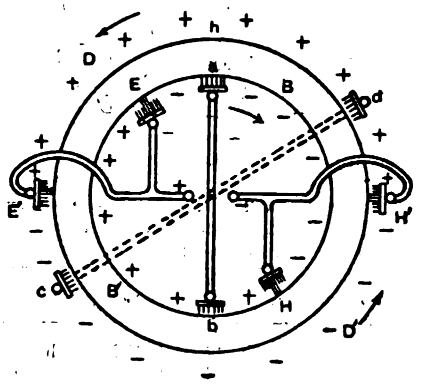

FIG. 5.

should be exposed to the influence of a positive charge on the plate D; consequently, to make sure of proper working, plate D must not be liable to reversal opposite it. Hence in the case of this plate the diametral conductor should be passed before the point *h* is reached. The second conductors should be placed at *c d*. The angular distance from *a b* to *c d*, that is to say, between the lines of sign change on the plates when the electrodes are too far apart, should be sufficiently great to make sure that in front of the combs the region of useful induction on the plate in front is enough to bring about the change of sign. In the contrary event the conductors are powerless to prevent reversal. On the other hand the conductors should not be too close to the combs under pain of diminishing the effect; 30deg. at least is the best distance off. In order to give oneself enough latitude, and to ensure constancy of sign, it is therefore necessary to provide the diametral conductors with discharging parts capable of very rapidly reversing the charge of the plates. I employed first of all the ordinary brush conductors of the Wimshurst machine, but did not allow them to touch the knobs. With this arrangement the flow of electricity was too slow. With combs on the two conductors the action was quite satisfactory. If brushes are employed on the diametral conductors, these brushes must not touch the plates under pain of immediate extinction of the action. In the Voss machine, as is well known, the diametral conductor is provided with brushes which touch the knobs on the plates. This is no defect, since the fixed inductors support the charges of opposite sign, which would, without them, rush to meet each other viâ the diametral conductor. But in the Wimshurst machine there are no fixed inductors, and each of the charges which acts as an inductor would at the same moment find itself in communication with a charge of opposite sign. Complete extinction would, therefore, necessarily be the result. The machine also stops if the combs are provided with contact brushes, though only when the electrodes are closed. With the electrodes open it works well this way. This eccentric behaviour is explained by the same principles. In the electrode circuit, as in the case of the Voss machine, I put combs in order to ensure an easy flow and to make use of a large surface of plate, and brushes to obtain spontaneous excitation. This latter seems to me to be brought about in much the same way as in the ordinary pattern—that is to say, as is well known, somewhat less perfectly than in the Voss. I should say, however, that I have not been able to assure myself yet that the machine is really and truly self-exciting. Throughout the whole course of my experiments the atmospheric conditions were persistently unfavourable, and the ordinary Wimshurst machine did not excite itself better than mine. However this may be, once excited the new machine keeps its charge exceedingly well, and in this respect, and in respect of ease of excitation, it is undoubtedly far superior to the Holtz machine.

To sum up, this is how I have arranged my apparatus: In front of one of the plates two combs on a horizontal diameter; before the other two combs 60deg. from the former; the two left-hand combs being united to one electrode, the two right-hand combs to the other. These combs are provided with contact brushes. At a distance of from 30deg. to 35deg. from the combs in the direction of rotation of each plate there is a diametral conductor carrying combs without brushes. The distance between the two conductors is about 50deg.

The following are the comparative tests of this machine made with the aid of the Lane bottle:—

—	*n*	*e*
Entirely new pattern	25·5	180
	26·0	189
	25·5	186
Pattern with a single diametral conductor	27·0	207
Pattern without conductors	25·5	203
Ordinary Wimshurst	25·0	90
	27·5	99
	27·0	101

The output is therefore twice that of the old pattern.

As is well known, Mr. Bonetti has recently considerably improved the Wimshurst machine from the point of view of output by giving it ebonite or glass plates without sectors and by increasing the number of the brushes on the conductors. It is evident that these modifications in no way alter my theory of the apparatus; every experiment, on the contrary, establishes it. All I have said as to the action of the ordinary machine is applicable to this new pattern. First of all, we must frankly renounce the horse-shoe shaped combs, as the following results prove:—

—	*n*	*e*
Entirely new pattern	51	104
	51	96
	51	100
Two straight combs and two diametral conductors	48	98
	53	108
Two straight combs and one conductor	53	100
	54	107
	55	118

If, now, I transform the Bonetti machine in the same way as I have transformed the Wimshurst machine, we shall have in Fig. 5, in place of the combs at E′ and E and at H and H′, the rows of brushes which M. Bonetti mounts on his diametral conductors, and on these I put combs without brushes similar to those employed in Fig. 5. The useful output is again doubled, as the following table shows:—

—	*n*	*e*
Ordinary Bonetti machine	74	79
	75	80
	77	81
Altered Bonetti machine	60	163
	64	173
	66	167

These figures, I repeat, have nothing absolute about them in view of the imperfection of my apparatus, but they leave no doubt as to the attainment of an increase in the output, in exact accordance with the provisions of theory.

It is therefore permissible to hope that the Wimshurst type of machine, which has been so greatly appreciated ever since its first appearance, on account of the ease with which it can be excited and on account of its constancy, will now become equally valuable on account of its output. Up to the present it has been markedly inferior in this respect to the Holtz and Voss machines. In the future it may be compared not disadvantageously with these machines.

ELECTRICAL TRANSMISSION OF POWER, WITH SPECIAL REFERENCE TO MINING OPERATIONS.*

BY H. T. HAWS.

In electrical transmission of power there are two cases to be considered, *i.e.* :—

(1.) Transmission over distances measured by the foot or yard.
(2.) Transmission over distances measured by the mile.

In this Paper I intend to deal principally with the latter.

Broadly speaking, there are two ways in which you can transmit energy from one point to another. Let us assume that the primary source of energy is coal, and the energy is not required at the pit's mouth, but at some works one mile away ; then in this case you could convey the coal by cart from the pit's mouth to the works where it is required, or else you could burn the coal under a boiler at the pit's mouth, use the boiler to drive an engine, and transmit your energy to the works by wire rope, or in some other mechanical way. The first is obviously the more economical of the two, even if the distance is short, but the two cases are utterly different—on the one hand you transmit the substance from which you obtain your energy, while on the other you transmit the energy itself—you transmit energy, first, in the stored form, second, in the live form, if I may be allowed to call it so.

The most important sources of power in Nature are corn, coal, and falling water. By the term corn I mean energy obtained from vegetable food stuffs by means of horses and other animal engines ; by coal I mean energy derived from coal, &c., by means of some heat engine. Energy derived from corn and coal is generally transmitted in the stored form ; while energy derived from water is generally transmitted in the live form. Now, in electrical transmission of power you can obviously transmit it in the stored and in the live form ; you could (to go back to the example of the coal pit and the works) use the engine which is being fed at the pit's mouth by your boiler to drive a dynamo, which in its turn charged some accumulators ; these you could transmit by some vehicle to your works, and there set them to drive a motor, or you could convey the current direct to your motor by means of insulated wires. The former would be a case of stored transmission, while the latter would be a case of live transmission ; this latter is what is generally meant by "electrical transmission of power."

Before entering upon electrical transmission of power in the "live" form, I will stop to investigate the capabilities of electrical transmission in the "stored" form. You could transmit energy in the stored form, first by carrying coal, and second by carrying secondary batteries. Now, it is a well-known fact that a sack of coal contains much more stored energy in it than a secondary battery of equal size and weight ; it is much cheaper, its carriage is less expensive, and it requires less care in transmission. Thus we see that if the primary source of power is coal it would be more economical to convey the energy in the form of coal to your works, and there turn it into useful power by boiler and steam engine, than to convey the energy in the form of secondary batteries and turn it into useful power by a motor, not only because of the saving in carriage, but also on account of the smaller capital outlay and the loss of energy in the battery itself. But when the primary source of power is not coal, but falling water, it is easy to prove that electric transmission in the stored form is the best and most economical way of transmitting your power (that is, in the stored form) to any distance ; the only method that can be compared with it is compressed air, as largely used in France on the "Popp" system ; but, looking at the efficiency of the Popp system as compared with the efficiency obtainable by using electrical transmission in the stored form, we find the total efficiency of the Popp system to be 26.7 per cent., as compared with 56 per cent. given by electrical storage, or nearly twice as great (these figures are obtained from a Paper of Prof. Kennedy's, read before the British Association's Meeting at Cardiff in 1889). Thus we see that if power has to be transmitted from a waterfall to a distance in the stored form electricity is the only agent that need be considered.

The system of power transmission, or to be more correct, power distribution by storage batteries, is in use in this country. I mean the working of tramcars by accumulators which are charged at a central depot and distribute power when it is required for the propulsion of the cars. Touching the transmission of stored energy from one place to another other than by batteries, there are two cases to be considered, namely, carriage of coal and corn, both combined with proper appliances for converting stored energy into live power at the end of the line of transmission. Mr. Kapp, in his renowned Cantor lectures, proves pretty conclusively that these two methods are greatly superior to electrical transmission of power by storage batteries, provided the primary source of power is coal or corn, and he goes very deeply into this subject. In fact, taking batteries as they are at present, their use as agents in the transmission of power is only justifiable where the direct transmission by means of wires cannot be employed. The only case of electrical transmission of stored power which as yet has attained to practical importance is the use of secondary batteries for locomotive purposes, but you have heard enough on this subject at the Institution's meetings on "Electric Traction."

* Paper read before students' meeting of the Institution of Electrical Engineers.

ELECTRICAL TRANSMISSION OF LIVE POWER BY MEANS OF INSULATED CONDUCTORS.

The Line.—It is a well-known fact that overhead conductors are much cheaper to construct than conductors placed underground, and the longer the distance of transmission the greater is the discrepancy between them, as the following table will show :—

Transmission Plant for 5 H.P.

Distance.	Annual cost per h.p. delivered.		Difference.
	Overhead.	Underground.	
Miles.	£	£	£
1	22·8	33·6	10·8
2	25·6	47·2	21·6
3	28·0	60·0	32·0
4	30·6	74·0	43·4
5	33·0	87·0	54·0

All other things being equal.

But some people object to overhead conductors—and so do I—in a town ; but where the transmission takes place across country, as it probably would in conveying energy from a waterfall to drive a mining plant or a mill, &c. I should certainly advise carrying the conductors on poles—in fact, it would be waste of money to bury the conductors. Now, in long-distance transmission the line is the most important factor in the cost of construction, but for ordinary workshop transmission the line is not so important so in the former case it is advisable to have the leads as small as possible.

In designing large power stations that are, say, worked by a waterfall and have to supply power some miles away, there are some important points to be remembered. Both generators and motors should be multipolar, as this gets over any side drag which would occur in a two-pole machine, also magnetic leakage is minimised, and for a given speed you can obtain a greater E.M.F., which is essential to efficient working ; also for a given power multipolar machines are lighter than two-pole machines. As a rule, a good dynamo will make a good motor if you give the dynamo brushes a forward lead and the motor brushes a backward one. For efficient working what we require is high voltage at the generating end of the line, so that the leads may be small, and a large torque combined with a certain speed at the motor end of the line ; and if we were only to consider the electrical efficiency of the distribution, the higher the voltage we worked at the greater the efficiency. But there are other things to be taken into account, viz., insulation, &c.

Now, before going into the special branches of electrical transmission of power, I will say a word or two about the controlling and regulating of motors. What we want in practice is a constant speed, no matter how the load alters. This is what a steam engine is supposed to give. There are two cases to be considered : (1) When you work your motor off the electric light mains at constant pressure ; (2) when the supply of current is obtained from a generator erected especially for the purpose at constant or variable pressure (the regulation of current and pressure being automatic), as in long-distance electrical transmission from a waterfall. You all know that for regulative purposes a series-wound motor is no good, as when the load is increased the speed is slightly decreased, and current increases ; this strengthens field and raises counter E.M.F. ; this will check the current, and a further drop of speed will ensue until a stable condition of affairs is obtained at a lower speed. The same thing occurs if we take off some load, but in the opposite direction, *i.e.*, the motors tend to race ; but, on the other hand, a shunt motor is almost a self-regulating machine. This fact was first pointed out by Mr. Mordey in an article in the *Philosophical Magazine* of January, 1886. The only drawback to shunt motors is that at starting you must insert a resistance in the armature of the machine. This is done in very many different ways in practice ; it can be done automatically by placing a resistance permanently in the armature circuit, and causing it to be short-circuited by means of a centrifugal regulator fixed to the armature shaft, and so arranged that when the speed has obtained a certain value the balls fly out and release a spring which closes a switch. This centrifugal regulator will also serve to prevent your using too much current, as the speed will drop slightly and the resistance will be automatically reinserted. But if you are taking current, not from the electric light mains, but from a plant erected specially for the purpose, you can have perfect regulation of speed with either series shunt or compound machines; so in the first case

Digitized by Google

you can only get good regulation with a shunt machine, but in the latter you can get good regulation with any machines the generators are constructed to work.

A few words about the supply of power in small parcels from central station supplies. Electromotors are not very largely used in London or suburbs, notwithstanding the enticement electric light companies offer by charging less for the current used for power during the daytime than if used for lighting purposes.

The St. Pancras Vestry have about 22 motors on their mains, aggregating about 70 H.P. The Bradford Electric Light Company have something like 40 motors, and they had great trouble at first with starting arrangements; but I believe they now use a liquid resistance combined with an automatic time starter. The Norwich Electric Light Company have mostly shunt motors, the special starting arrangements of which I will sketch on the board (Fig. 1). The other companies in London and district have comparatively few motors on their circuits; in fact, I was very much struck when visiting some of the central stations last year at the little power they supply for motive purposes, but I have no doubt that in five or six years this will have altered, and I should not mind saying that in eight or ten years the electric light companies in London will work at full load day and night.

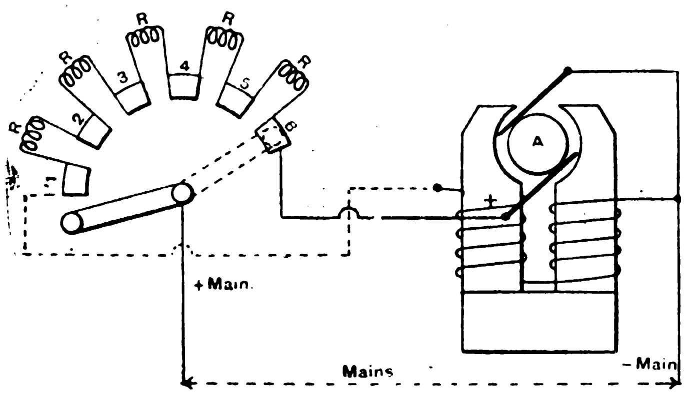

Fig. 1.

Electrical Transmission of Power in Large Engineering and other Workshops.

All practical electrical engineers must acknowledge that they have a rival in the distribution of small parcels of power, even if its merits are poor. I mean gas and oil engines. What brought the gas engine up to its present state of efficiency? Why, the competition of electrical engineers. Now, according to Mr. Crompton, the power obtained from an electric motor costs one-third the price of that obtained from a gas engine, while it is always at hand, requires no pulling round of heavy flywheels, lighting up, turning cocks, lubricating and the hundred and one things required to be done before a gas engine will start. Its speed is very regular and does not jump up and down with the characteristic jerk of a gas engine besides you can turn a motor on and off as much as you please, while it does not pay to keep stopping and starting a gas engine.

The advantages of the electric motor for working cranes, lifts, &c., over hydraulic power is at once evident. The electric motor demands power from the source of supply in proportion to the work it is called upon to perform, while if you make an hydraulic crane lift a weight smaller than its maximum, the amount of water supplied and pressure, provided the elevation is the same, is the same as that required for maximum load, and I believe you can get a dead loss of 80 per cent. by using hydraulic cranes below their maximum load; hence the advantage of using an electric motor on the crane which will hoist, slew, and propel the crane simultaneously or separately.

In large engineering works electrical power has many advantages over steam power, and I fail to see any important advantages the steam engine has over the electric motor. There can be no doubt that it is much more efficient to have one or two large steam engines directly coupled to dynamos, the former fed by a boiler working at high pressure, and transmit your energy to different motors placed in the various shops, than to have a small steam engine and boiler (necessarily inefficient) working an enormous amount of countershafting placed in every shop. Countershafting means a large percentage loss of power, due to overcoming friction, heating of bearings, besides a certain amount of danger, putting aside such minor inconveniences as noise, smoke, dirt, &c.; and what can be done and is done in large works is the abolition of a large amount of countershafting, by directly coupling a motor to each large machine which may be required to work intermittently, and using as many motors as possible, because now small motors can be made with comparatively large efficiencies, much more so than you can make small steam engines efficient as compared with large on s. The only works in which I have seen electrical power used very largely are Messrs. Siemens' works at Woolwich; there they have some large Willans engines directly coupled to continous-current dynamos at their central station, and this supplies the different shops with power by overhead conductors. In the india-rubber shop there are four machines, each one directly coupled to a 40-H.P. motor; but I have no doubt nearly all of you have been over Messrs. Siemens' works; if any of you have not, I would strongly advise you to take the first opportunity of doing so.

Electricity in Mining Operations.

The rest of this Paper I have devoted to electrical mining operations. In electrical transmission of power to mines, either from a waterfall near by or from a generating station, there are some difficulties to be overcome which do not occur in any other case. They are: (1) Falls of earth, &c., from roofs and walls and creeping of the floors; (2) water; (3) explosive gases. These require different methods to overcome them, and only an engineer experienced in this kind of work can do so successfully, *i.e.*, a man possessing a thorough technical knowledge of electrical subjects, and also a practical knowledge of mining. Strange to say, there are very few men in England possessing these necessary qualifications. There are plenty of men possessing the one, and thinking they possess the other, but I am of opinion that the number of good electrical mining engineers in England can be counted on both hands; this is perhaps one of the reasons why electrical mining has not made as rapid strides as you might have expected it to do. Much defective work has been done in this branch of power transmission, largely owing to that great bugbear in electrical as well as in civil and mechanical engineering. I mean accepting the lowest tender, no matter who tenders for the job, whether he is the local plumber or gasfitter, as long as he sets it to work, and it passes the fire insurance inspector or Board of Directors.

In mining work it is common to have the generating plant above the ground and the dynamo driven by a separate engine (in cases where steam engines are used for other purposes), and in English collieries, sad to say, electric plant plays a very small part in the main machinery; very often they do not have even a separate dynamo house.

Mining engineers have now begun to see the large saving in fuel and steam by using high-pressure boilers to drive quick-running engines; but I think the Lancashire boiler is used mostly, and I should feel inclined to say it was preferable to the water-tube and locomotive boilers, which seem the rage just now, because, although the water-tube and locomotive boilers are very superior in raising steam quickly, yet they are more difficult to clean, and require more skilful labour to repair them, whereas a good Lancashire boiler with cross tubes, and working at a pressure of but 80lb. to 120lb. per square inch, is fairly efficient, requires little attention, especially if fed with coal (which in a colliery is never of the best and is mostly dust) by mechanical stokers, and can easily be repaired.

Now, with regard to generators, I take it for granted direct driving is chosen for reasons which were put so admirably before you in our secretary's Paper of last November. Shall we have an open or closed type of engine? There are various opinions on the subject; but I think, taking into account the probable nature of the engine house, the closed type engine is the best (such as Messrs. Willans and Robinson's), as although it is more difficult to get at it cannot get dirty, and there is less risk of accidents.

The question of system employed, and also the pressure the generators must work at, depends on how far the engine house is from the mine and on local conditions. If it is a case of long distance transmission, as from a waterfall a mile away, then perhaps it would be more economical to use high-tension continuous current with transformers; with short distance transmission 500 volts is a very common pressure, but it must be remembered that it is not safe to work portable coal cutters with a greater voltage than 50 volts, especially if they are worked by non-electrical miners, so it is common to transform your current down again before using it to drive coal cutters, drills, &c.

I regret to say that owing to shortness of time I am unable to say much about the polyphase system of distribution; but it has been used very little, if at all, in this country.

Conductors.—In mining operations there are very many classes of cables which are suitable, and they differ mostly in the insulation employed and the means used to protect them from water and injury; also in the methods employed to prevent the cable sparking if it is severed or injured. The best two kinds of insulation used are vulcanised fibre and bitumen compounds: the former is the most expensive and is better for small leads, while the latter is cheaper, and is, therefore, best for large trunk mains; but as bitumen loses its insulating properties considerably if it gets wet, it is always necessary to cover it with lead, which is generally again armoured with iron or steel wire. This form of bitumen cable is nearly always made concentric. It is found advisable to use a duplicate system of mains in mines, connected in parallel to omnibus bars, and also to use small conductors limited to 19/14 S.W.G., as in mining it is often a matter of impossibility to make repairs during the drawing of coal. Thus, if one cable broke down, the other one could supply the current until the

Digitized by Google

fault was located and put right. This would obviously prevent the occurrence of any sparking. Another advantage of using small mains over large ones is that the former are relatively lighter, and are therefore easier handled and fixed in position. Further, the cost of repairs to the smaller cables is generally much less than to larger ones, owing to the greater ease with which the joints can be made, &c. Bare return concentric cables are largely used; they are cheap, and prevent to a certain extent external sparking, and if armoured are very strong.

Safety Cables.—These are generally made of two conductors in parallel, insulated from one another, and one of the conductors breaking before the other actuates a magnetic cut-out which opens the main circuit before it is actually broken in the mine, thus preventing sparking occurring in the mine itself.

The Atkinson Safety Mining Cable.—This consists of two conductors in parallel insulated from one another except at the ends, the inner one being in the form of a spiral which, when a stone falls on the outer conductor, and breaks it (owing to the resistance it offers), stretches out, and is not fractured, but all the current going through this thin wire blows a magnetic cut-out in the engine room, and thus prevents sparking in the mine. The efficient working of this cable depends on (1) perfect insulation between the two conductors, (2) the continuity of fine-wire circuit being preserved during fall. I think the practical use of these cables may be doubted.

There are very many safety devices used to prevent sparking, some employing elaborate systems of magnetic cut-outs, &c.; but, taking it all round, none of them offer greater security from external sparking than an armoured concentric cable, such as I have here, either buried in the ground or hung very loosely with plenty of slack from the roof or sides of the mine. If a stone or lump of coal falls on it, it will either bury the conductor in the ground or else cut through the outer conductor; but the other side of the outer conductor remaining, the magnetic cut-outs will probably go before any harm occurs; success lies in hanging the conductors loosely, so as to prevent instantaneous cutting of the cable. As far as I am aware, there has never occurred an authenticated case of coal gas having been fired by the severing of a concentric cable, although the possibility of its occurring is evident.

Safety Motors.—Various methods have been devised for constructing a good safety continuous-current motor. The first method was to enclose the whole motor entirely in a metal case, but it was found that the quantity of air enclosed was too large to be safely fired. The next course was to only enclose the commutator and brushes, and Messrs. Easton, Anderson and Goolden have constructed an excellent safety mining motor on this plan, which I have not time to fully describe. The main objection to enclosing the brushes is that the design of the brush gear is complicated, and therefore the adjustment of the brushes is rendered difficult, especially to unskilled hands. The only real safeguard against explosions from sparking at the brushes and commutator is to get rid of them altogether, and this can be easily done by using polyphase motors.

The polyphase system, there is no doubt, is the system of the future, and it will outdo all others, especially in mining work. The advantages of the polyphase system over any others are:—

(1st.) Sparking is impossible.

(2nd.) Racing is impossible, since speed of rotor can never exceed that of synchronism with generator.

(3rd.) Speed regulation can be accomplished by means of impedance coils in a small space without any fear of sparking, as no part of the circuit need be opened or shunted, as is the case with ordinary regulative resistances.

The sole advantage continuous-current motors have over polyphase motors is in regard to their starting torque. From this point of view the series-wound motor is the most efficient motor that can be built, as a polyphase motor has to have a starting resistance in the rotor circuit.

A few words with reference to electric coal cutters and drills. One of the difficulties of electric coal cutting seems to me to be that they cut the coal too quickly, and the coal cannot be removed fast enough from the workings, and so the cutter is not used continuously; but this obviously can be got over by constructing smaller coal cutters, say to cut five to ten yards per hour instead of from 20 to 40, as they sometimes do. It may be remarked that one of the best electric coal cutters, with two men to work it, will hew as much coal per hour as 20 or 30 men could; and as the number of accidents in a mine is directly proportional to the number of men employed, the introduction of electrical coal-cutting machinery would obviously largely decrease the loss of life from accidents.

Electrical coal cutters may be divided into two classes—(*a*) bar cutters, (*b*) rotary wheel or disc cutters. Under the first head are included all machines which have a cutter bar revolving either at right angles or parallel to the face of the coal. This type has proved by far the most successful in this country and America, the best-known being (1) the Goolden-Atkinson bar cutter, (2) the Jeffrey machine, of American origin. In the former the cutter bar is usually geared to the armature shaft by a pair of cast-steel double helical wheels running in oil, and makes from 300 to 400 revolutions per minute, and the motor is nearly always series-wound; the latter is different from any machine of English origin, being made to suit the American coal seams. Under the second head may be mentioned the Yorkshire Engine Company's side-wheel cutters and the Thomson-Houston coal cutter; but, owing to the great success of these machines when driven by compressed air, practically no difference has been made when worked electrically.

I will now describe some mines in particular which are worked either wholly or partly by electricity in England.

Abercanaid Colliery.—The generating plant here consists of a Marshall's engine, compound, 13 by 21, steam pressure 140lb., flywheel 12ft. diameter; a Crompton dynamo, 180 amperes at 500

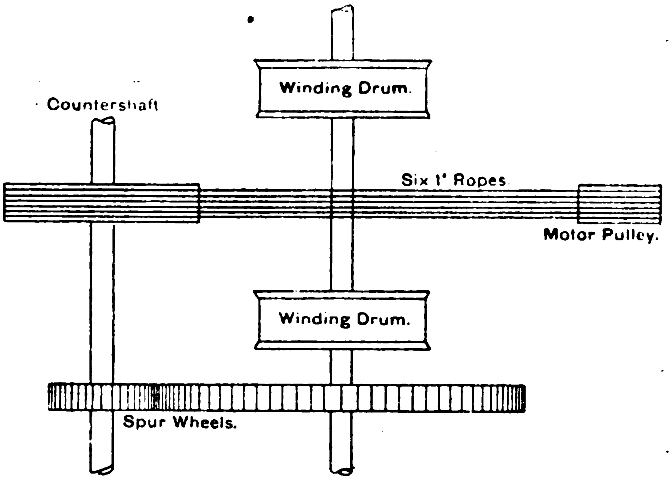

FIG. 2.

volts, 550 revolutions per minute. The current is carried by cables down the shaft and through the workings 1ft. underground to a point three-quarters of a mile from the generating plant; here is the hauling engine, motor, and plant. The system is the main tail and rope haulage. Two drums, 3ft. 6in. diameter and 1ft. broad; the drum shaft is driven by spur gearing from a countershaft, which is driven by a Crompton motor by six 1in. ropes. I will here sketch the arrangement (Fig. 2). The motor will work at 100 H.P.; it is a series machine. The cable used for transmission of power is 3,200 yards of 37/14 S.W.G. copper, insulated with vulcanised bitumen; it is armoured heavily with a double sheath of No. 8 steel wire; external diameter, 2·15in.

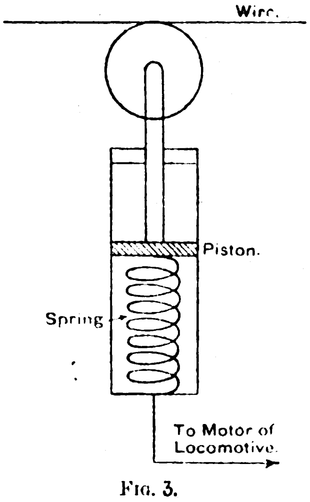

FIG. 3.

Greenside Silver Lead Mines.—The generating plant consists of a 100 B.H.P. "Vortex" turbine, driving an Immisch compound dynamo four-pole type, 100 amperes, 600 volts, 500 revolutions. Water is taken 360 yards to dynamo house by 15in. pipe. Length of transmission 1¼ miles. Here is an Immisch motor driving winding drum hoisting 10 cwt. at 360ft. per minute; 350 yards further on is another motor driving a three-throw horizontal pump. Midway between these two motors a constant-current transformer is placed to transform down to 200 volts for working an electric locomotive (Fig. 3). Length of line, three-quarters of a mile: average load, twelve tons; speed, five miles an hour; contractors, Acme and Immisch Electric Works Company.

East Hull Colliery.—Generating plant consists of vertical high-speed steam engine driving a Crompton continuous-current dynamo. Length of transmission, 1·7 miles. There are three motors in the mine driving pumps.

INFLUENCE MACHINES.

Three articles which we print to-day in our columns on the topic of Influence Machines are evidence of the continued attention which is being given by electricians to this class of apparatus. One is from the veteran Professor HOLTZ, whose pioneering researches of 1866 have never really ceased; another from our own Mr. WIMSHURST, who has done so much to give to the influence machine the qualities of reliability and efficiency which is so sorely needed; while the third is from the pen of Father SCHAFFERS.

With the question of priorities in invention that incidentally peeps out we need not concern ourselves much. No one in this country grudges to HOLTZ the reputation won by his patient and protracted labours any more than such recognition would be grudged to his contemporaries TOEPLER and VARLEY for their contributions to the subject. Mr. WIMSHURST's single-hearted and disinterested enthusiasm is known to all electrical men; they appreciate the entire honesty and originality of his work. To have produced machines which neither lose nor reverse their charges in action, and which never fail in their excitation, is no small achievement, and one not to be belittled by saying that self-excitation is a secondary detail. The answer to the detractor is to be found in the thousands of influence machines that are in use to-day, and would never have existed but for the work of WIMSHURST.

The main point raised now by the Papers of Father SCHAFFERS and Prof. HOLTZ is the operation of that part of the machine which is connected to the pair of discharging knobs, or, as Father SCHAFFERS terms them, the electrodes. It were to be wished, indeed, that in both Papers the phraseology were a little more strict. Prof. HOLTZ uses the term "intensity" of output apparently as a synonym for maximum length of spark, or, perhaps, for the electromotive force that is concerned in the maximum length. Father SCHAFFERS starts off by a reference to the "combs" which discharge the sectors, meaning thereby, as it appears, the horseshoe-shaped combs which communicate with the discharging knobs; and he speaks of the "flux," not meaning (as might have been supposed by analogy with the magnetic flux) the total number

Digitized by Google

of lines in the electrostatic field, but as meaning the current which the machine sets up. Father SCHAFFERS seems to imply that there is something wrong in the usual method of describing the elementary action of the influence machine as well as in its construction. When carefully examined, his argument amounts to the following contention. The discharging part of the machine, usually consisting of two horseshoe-shaped combs connected to a pair of discharge knobs, does not act simply as a discharging apparatus; it also acts at the same time as a neutralising conductor, aiding or replacing for the time being in the exercise of that function one of the two oblique diametral conductors. Here he is undoubtedly right: it does so aid in addition to acting as discharger. But that is no reason for not calling it after its principal function rather than after its incidental operation. Many years ago Mr. WIMSHURST demonstrated that this discharging apparatus is no necessary part of the machine. He constructed and presented to the Royal Institution a simple pair of discs furnished only with the two oblique diametral conductors and the axis for revolution, which nevertheless excited itself and constituted a perfect machine. All else is merely accessory. He traced out the operations in the revolution of the discs and described the currents in the two conductors; the mutual repulsions in two of the opposite pairs of quadrants, and the mutual attraction in the other two, just as we know them to-day. The older Holtz machine used these currents directly, the operation of procuring the spark discharge consisting in opening a gap between two knobs inserted (and closed together at starting) in one of the two neutralising paths. Prof. SILVANUS THOMPSON pointed out ten years ago that there was the same difference between putting the discharging gap into one of these two neutralising circuits and putting it into a special discharging circuit as there is in dynamos between putting the lamp in series with the magnetising coils and putting it in parallel to them as a shunt. The series dynamo does not excite itself when the circuit is open, and is liable to reverse its polarity. The shunt dynamo keeps its polarity without reversing; excites itself best on open circuit, and loses its charge when short-circuited. A clear hold on this useful analogy would help both Father SCHAFFERS and Prof. HOLTZ to explain exactly what they are striving for. Father SCHAFFERS' contention that one of the diametral conductors is superfluous and harmful, as diverting current from the useful path of discharge, leads him to remove it altogether. Suppose we had a compound dynamo having a badly-designed shunt winding which diverted too much current from the lamps, we might justly say, Let us remove the shunt, and we shall increase the output of the machine. We remove it, and lo! we find we have got a series machine, with its inability to excite itself on open circuit, or, unless we add something, to perform the function formerly performed by the shunt. That the two branches of the horseshoe-shaped combs of the discharging apparatus do not act equally has long been known. To remove half of them and put straight combs opposite one face only of the machine may remedy this "defect." Mr. WIMSHURST long ago found that a better course was to build the combs so that the front comb was a little in advance of the back comb at one side and a little in retard at the other side of the machine. If we remember rightly, this construction was actually used in the large machine with 7ft. plates which Mr. WIMSHURST built for the national collection at Kensington.

In the article by Mr. WIMSHURST we have a criticism of and a rejoinder to the comments of Prof. HOLTZ. Mr. WIMSHURST's remark that the metal carriers or "sectors" are necessary evils is one that we entirely endorse. Their presence is inevitable in a climate such as ours, otherwise the machine relapses into that state of unreliable action from which it is Mr. WIMSHURST's great merit to have effectually rescued it. Though Mr. WIMSHURST does not reply specifically to Father SCHAFFERS, there is one point of curious difference as to fact between them. Father SCHAFFERS lays great stress on the alleged circumstance that the carriers, after having passed under a comb, are found to be over-neutralised—that is to say, actually charged with charges of reversed sign, which alleged fact he attributes to the influence exerted laterally by the charges upon the neighbouring undischarged parts of the plate. Mr. WIMSHURST passes the alleged fact in silence; and in his diagram represents the effect of passing a brush not as over-neutralising, nor as even quite neutralising the sector.

Mr. WIMSHURST's closing remarks for the encouragement of other workers meet with our entire approbation. Much as he has himself accomplished there is room for the efforts of future aspirants to fame. Probably a good deal remains to do in finding the most satisfactory disposition of details. It is now well recognised that the length of spark is limited by the internal insulation of the machine, and that the quantity of the output is proportional to speed and to the amount of surface charged and discharged in each revolution. The point that is yet not properly appreciated is that the operation of charging any sector or carrier and making it impart its charge to another part of the apparatus really consists in charging a condenser of a certain small capacity up to a certain potential, and then in artificially raising that potential by pulling apart the dielectric that lies between the charged carrier and the oppositely charged body with which it was previously in proximity. We shall not be able to increase the output of a machine of given size at a given speed until we understand how to increase the mutual capacity of the two parts when brought into proximity, or how to increase the degree of electrification of them without causing wasteful internal discharges in the operation of charging them and then separating them from one another. The contributions of Prof. HOLTZ and of Father SCHAFFERS may both aid to this end; but there are other recent workers whose efforts are also well worthy of consideration.

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(Continued from page 360.)

§ **47. Capacity Tests** (*continued*).—The Silvertown testing key designed by Mr. Rymer-Jones, illustrated in Fig. 142, is largely used in capacity or insulation tests. There are three ebonite pillars, two of which support horizontal contact levers movable about the point of support and provided with ebonite handles. The levers can be moved independently, but one of the handles carries a distance piece (seen in Fig. 143) which prevents them both touching the back contact bar at the same time. The back bar is fixed on the third pillar, and is curved or channel shaped, so as to present two contact surfaces—one for each lever. The contact surfaces have springs pressing in an upward direction, so that as the levers move on to the surface of the springs good contact is made. The ends of the levers are tipped with gold, and the springs are of platinum, these metals having been found to wear best and keep a perfectly clean surface. The high insulation obtained by the pillars, the accessibility of all the parts, the good contacts made by the levers, and the adaptability of the key for different tests are its chief advantages. In one form, as in Fig. 142, a central contact bar *a* can be moved up into position when the key is required as a reversing key, or moved away when the

* Copyright. All rights reserved.

Digitized by Google

key is in ordinary use. The key, as arranged for reversing and discharge, is shown in plan in Fig. 143. By moving the handles of the key apart, and so pointing the levers towards each other, the two levers can be entirely insulated from the back contacts and from each other.

For Gott's capacity test it is convenient to use two of these keys as in Fig. 144, one for charging or earthing the condenser and the other for connecting galvanometer to slides or taking the absorption discharge. Another is also shown connected to the battery as a reversing key.

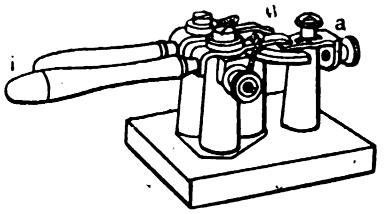

Fig. 142.—Rymer-Jones Key.

So arranged, the test is started by putting the levers of both keys to the right, thus earthing the condenser and cable and getting rid of all residual charge. This is done between each successive trial to balance. The balance key is then insulated and galvanometer key opened. The charge is then applied for

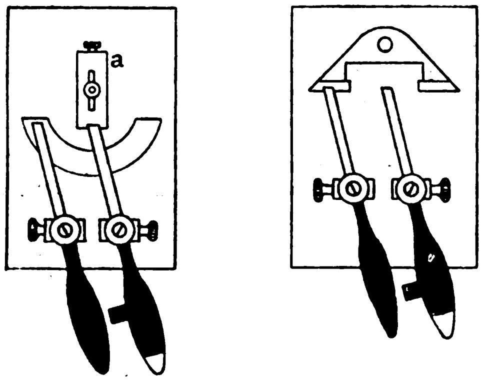

Fig. 143.—Rymer-Jones Reversing and Discharge Keys.

a given number of seconds by putting charge key to the left. Galvanometer is then connected to slides by putting balance key to the left. If there is a deflection the slides are readjusted until, on repeating the charge, the deflection is *nil* or nearly so. Want of balance is corrected afterwards by the absorption discharge, so that it is not necessary to obtain a perfect balance on slides.

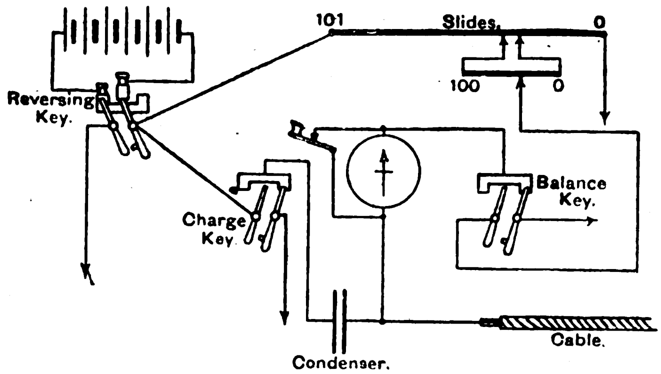

Fig. 144.—Gotts' Test with Rymer-Jones Keys.

The absorption discharge is now obtained by first insulating the balance key, opening galvanometer key and charging the condenser and cable again for the same period of time as before (slide index being at position for balance). Immediately after the period of charge the charge key is put over to the right, thus earthing the condenser, and after an interval of 3 seconds (the earthing period) the balance key is put over to the right, thus earthing the galvanometer and producing the absorption discharge deflection. A shunt may be required on the galvanometer for this deflection, and if so the same shunt for convenience should be used when getting the equivalent deflection on the slides. The slide index is moved to a position near the zero or earth end, and the balance key put to the left, thus connecting galvanometer to slides. The slide reading equivalent to the absorption discharge is then calculated and added to or subtracted from the original slide reading, as described above, and the capacity of the cable worked out by the formula given.

This key is in use in the General Post Office, and a full description of it is given in Kempe's "Handbook of Electrical Testing." The Silvertown Company also use a pair of these keys mounted on one board for testing the insulation resistance and inductive capacity of cables, the permanent connections being those shown in Fig. 145.

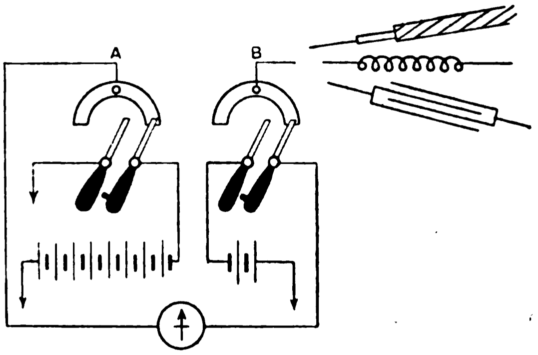

Fig. 145.—Combination Testing Set.

48. Calibrating the Slides.—The slides afford a most convenient means of measuring any potential or difference of potential direct in volts, answering the same purpose in fact as a potentiometer. A fairly large battery is connected to the extreme ends 0 and 101 of the slides (Fig. 146), and a standard cell, galvanometer and key are joined between the travelling contact *c* and the terminal 0 of the left-hand box. The battery and standard cell are joined so that their E.M.F.'s are in opposition. Balance is obtained in the usual way by

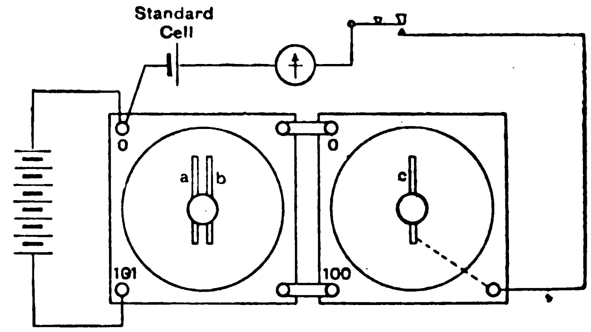

Fig. 146.

moving the contact arms (first the arms *a* and *b*, and then the single arm *c*), meanwhile tapping the key at intervals until a position of the arms is found at which no current passes through the galvanometer when the key is closed. At the particular point of contact on the slides so determined the potential is equal to the E.M.F. of the standard cell. This will be clear from Figs. 147 and 148, which represent the same connections as Fig. 146, but in a theoretical form.

In Fig. 147 the thick horizontal lines marked 0 to 101 and 0 to 100 represent respectively the resistances in the two boxes of the slides. As previously explained, the arms *a* and *b* are insulated from each other and move together, always enclosing two of the 1,000 ohm coils between them.

The single contact *c* moves over a resistance divided into 100 parts, the whole of which is equal to the resistance of the two coils enclosed between *a* and *b* (viz., 2,000 ohms). These two coils are, therefore, equivalent to one coil only, and the difference of potential at the ends of this equivalent of a single coil

Digitized by Google

is subdivided into 100 parts. We have therefore 100 coils, each of which is 1,000 ohms resistance, and capable of subdivision into 100 equal parts. The total resistance is therefore 100,000 ohms, but it is scarcely ever necessary to take into account the actual resistance. All that is necessary to consider is that we have 100 coils of equal resistance, each of which can be divided into 100 equal parts, making therefore 10,000 equal parts or divisions. We may therefore still further simplify the diagram by a single line representing 10,000 equal resistances (as in Fig. 148), over which the potential falls uniformly. One travelling contact c moving over such a set of 10,000 equal coils amounts to exactly the same thing as the two sets of coils and travelling contacts in the slides.

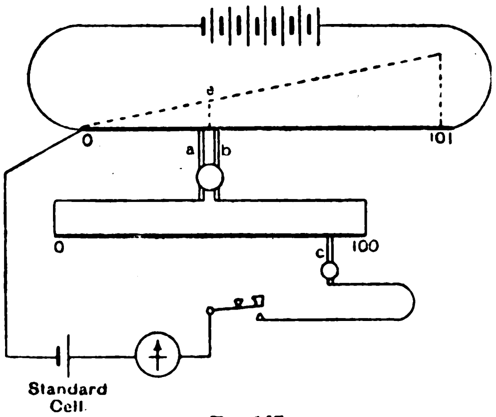

Fig. 147.

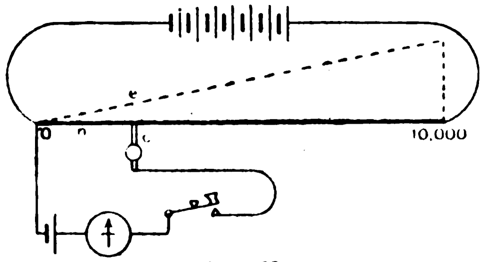

Fig. 148.

Suppose now that the slide reading is n divisions when the standard cell is balanced. We then have a direct calibration of the slides in volts, the difference of potential per division being equal to

$$\frac{e}{n} \text{ volts.}$$

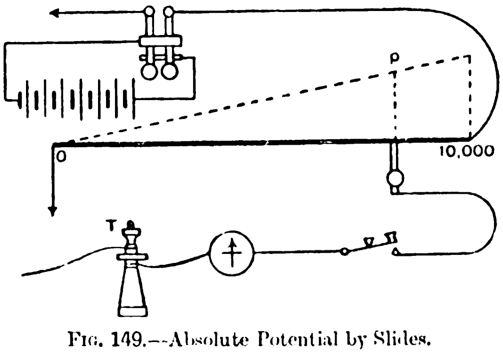

Fig. 149.—Absolute Potential by Slides.

For example, say the slide reading at balance is 967, with a standard cell of 1·45 volts; then the potential corresponding to each one of the 10,000 slide divisions is equal to

$$\frac{1{\cdot}45}{967} \text{ volts,}$$

and any other potential which it is desired to measure can be obtained in volts by multiplying the corresponding slide reading by the above ratio. For example, say we have a connection at the terminal T (Fig. 149) to a point in some circuit, the potential (p) of which is required. The battery on the slides (the same as used when calibrating) is connected to a reversing key, so that the right direction of current can be put on to oppose the potential p. Balance being obtained, say with a slide reading of 2,667, we have at once a direct measurement of this potential in volts, viz. :—

$$\frac{1{\cdot}45}{967} \times 2{,}667 = 4 \text{ volts.}$$

For the purpose of this test, the E.M.F. of the battery connected to the slides need not be known, but it must exceed any potentials that are to be measured on the slides, and, if altered at any time, a fresh calibration reading with the standard cell will be necessary.

(To be continued.)

ENGLISH INTERNATIONALISM.*

BY E. HOSPITALIER.

Our readers may reassure themselves. The subject of this article has nothing to do with Foreign Policy nor the Egyptian Question, provisionally settled by the "J'y suis, j'y reste" of our good friends across the Channel, who would like to make it eternal. The subject we propose to deal with is purely scientific. We propose to consider English internationalism from the point of view of the service which it may render to the cause of the unification of the symbols, notations and units of physical science. We have devoted ourselves for the past 12 years to this cause, in which we have up to the present met with more rebuffs than successes, and though we have often met with indifference, and sometimes with hostility, nowhere has this hostility been so keen as in England, the country whose marvellous system of units secures for it the compassionate admiration of all civilised nations.

After the Electrical Congress held in Chicago in 1893, a table of notations, abbreviations and symbols, which had been recommended by the Committee on Units, was printed and distributed in America by the *Electrical World*, and in France by *L'Industrie Electrique*. These symbols are slowly spreading. They have made their mark, and with time will end by imposing themselves. The establishment of a system of international symbols is not an easy thing, and it was necessary to compromise by taking letters representing quantities, some from one country and some from another, and here the truly international character of our neighbours shows itself. They have accepted without demur P as the symbol of power and W as the symbol of energy or work, but they will not hear of I for current, which they persist in denoting by the letter C, and as C was chosen for capacity, they substitute for this the letter K, thus, rather than change their custom in the slightest degree, destroying the economy of letters practised in the original plan. To accept the concessions of others, but to make none themselves, is characteristic of English internationalism. This was also recently shown in *The Electrician* of May 31, 1895, in connection with the symbols denoting magnetic quantities, and in connections with the names provisionally adopted last year by the American Institute of Electrical Engineers. This is the way in which our contemporary rejects the one and the other :—"Every individual is, of course, entitled to have his own opinion as to the relative merits of 'block' and 'black' letters ; but the use of 'block' letters having become well established in this country, where modern magnetism took its growth, we may be pardoned for refusing to countenance any further this anarchic tendency of every new writer on magnetic subjects to employ whatever symbols and terms seem good in his own eyes. The strange names which Messrs. Houston and Kennelly employ for the numerous magnetic units they refer to are quite unnecessary additions to the jargon of science, already sufficiently irritating, and they possess neither the sanction of authoritative nor of international usage, notwithstanding their adoption by the American Institute of Electrical Engineers. The hasty introduction of superfluous names and terms cannot be too strongly deprecated, both in the interest of science and of sense."

In its misoneism, as excessive as it is national, our contemporary falls into a double error, both with regard to the symbols of physical quantities and with regard to the units. This we will proceed to prove.

Modern magnetism has received its development in England. This declaration lacks modesty, but it is correct, and it affords us an argument in favour of "ronde" [German text] type. It was the Papers presented to the Royal Society in 1885 by Dr. Hopkin-

* From *L'Industrie Electrique.*

Digitized by Google

son and Prof. J. Ewing, which specially contributed to this development. Now as we write this article we have under our eyes extracts from the *Philosophical Transactions* of the Royal Society, and we assert that the symbols used to denote the magnetic quantities, $\mathfrak{B}$, $\mathfrak{H}$ and $\mathfrak{I}$ are in "ronde" letters. It was from the English Papers of Ewing and Hopkinson that we borrowed the symbols which figured in the table recommended by the Committee on Units of the Chicago Congress, and it is the English to-day who most oppose the use of "ronde" letters which were also employed by Clerk-Maxwell in his celebrated treatise !

We think we have found the reason for this hostility and for the change in symbols. "Ronde" letters at the time, about 1885, that the new contributions to magnetism appeared, were only to be found in a small number of printing offices, and they were replaced by Gothic letters, almost illegible, and ugly to look upon. The idea then occurred to an economical printer—"business is business"—to replace Gothic letters by the block letters which the English will not to-day let go. Should so much of the commercial spirit be allowed to enter the minds of men of science, and would it not be simpler to render homage to Maxwell, Ewing and Hopkinson by adopting "ronde" letters,* and abolish these horrible block letters, which disfigure a book and take an enormous time to write on the blackboard.

As to the employment of one and the same unit, the "gauss," to express the magnitude of the magnetic field $\mathfrak{H}$, and the magnetic induction $\mathfrak{B}$, nothing is more natural. In the electromagnetic system, these two physical quantities have the relation $\mathfrak{B}=\mu\mathfrak{H}$ on the fundamental hypothesis that μ is an abstract number—a simple numerical ratio. So long as the absolute dimensions of magnetic permeability have not been determined in terms of L M T, it will be logical and rational to measure $\mathfrak{H}$ and $\mathfrak{B}$ by means of the same unit; in the same way as the same unit, the centimetre, is used to measure lengths, breadths, heights, thicknesses, coefficients of induction in the electromagnetic system, and capacities in the electrostatic system. In all the Papers of Lord Kelvin, an indisputable authority in England and the entire world, are not resistances even expressed in centimetres? Does not Dr. Hopkinson express couples (torque) in joules in his investigations on tramways. Lord Kelvin, however, knows that a resistance is not a velocity, and Dr. Hopkinson that a couple is not work. Nevertheless, they make use of these units, and with good reason, since they are the result of logical hypotheses made with a view of establishing as coherent and simple a system as possible. On the day that a more advanced state of science permits of the suppression of these hypotheses, and of the establishment of the absolute dimensions of physical quantities, and on that day only, everything may be begun afresh, and new names created in great numbers, since it will no longer be legitimate to measure all quantities not having the same dimensions in terms of the same unit. But in the actual state of science, and in view of the fundamental hypothesis which serves as the basis of the electromagnetic system—an hypothesis which makes magnetic permeability a simple numerical ratio—it is coherent, logical and rational to measure $\mathfrak{B}$ and $\mathfrak{H}$ in terms of one and the same unit. It is more logical and rational, then, to express "resistivities," as our contemporary often does, either in ohms or ohms per cubic centimetre, a "resistivity" not being either a resistance nor the quotient of a resistance into a volume.

As to the utility of the names upon which *The Electrician* throws doubt, we must be allowed to inform our contemporary that there is no doubt about it, and that at any rate for educational purposes these names render the greatest service. They have the advantage of giving a concrete idea of the quantity measured and of indicating its nature by the mere enunciation of the name of the unit in which the quantity is measured.

As to the reproach that the magnetic units have not the sanction of international usage, "C'est une vérité de la Palice." These units date from hardly a year ago, and have not yet spread, and it is not the systematic hostility of *The Electrician* which will contribute to that end. But their use will extend in spite of it, as the metric system has spread all over the world in spite of the opposition of England.

* For the edification of our readers we reproduce below the four symbols most employed in magnetism, printed in the different types still in use:—

Italic capitals	*B*	*H*	*I*	*R*
German text	$\mathfrak{B}$	$\mathfrak{H}$	$\mathfrak{I}$	$\mathfrak{R}$
Block	**B**	**H**	**I**	**R**
Gothic	𝕭	𝕳	𝕴	𝕽

This table shows that gothic letters are neither legible nor easy to write. Block letters are too black, and it has been proposed to reserve them for photometric quantities, which are but little used. Italic capitals are partly employed for other quantities. "Ronde" letters, therefore, are specially suitable for magnetism.

The utility of international symbolism needs no further demonstration. Since 1893 "reactance" and "impedance" have made their scientific journey, and as an agreement has not yet been arrived at as to the symbols for these quantities, the divergences of writers in this respect are exceedingly curious. M. Blondel employed K and Z, Steinmetz *s* and *u*, MM. Bedell and Crehore K and J, &c. One can imagine the perplexity of unfortunate men who, wishing to study a subject, are first obliged to study the symbols adopted by different authors, symbols which they would be sure to confuse when comparing results. But in this matter of symbols we are amused to see the English denying, after ten years time, their scientific gods in order to save the expense of new type. What thinkest thou of thy fellow-countrymen, O shade of Maxwell?

LONDON COUNTY COUNCIL.

ELECTRIC LIGHTING LOANS.

At the weekly meeting of the London County Council, held at the County Hall, Spring-gardens, on Tuesday, Mr. Alfred Hoare moved the adoption of the Finance Committee's report, which recommended, amongst other matters, the following loans:—£7,000 to the Vestry of Hammersmith for the purchase of freehold land in Fulham Palace-road, to the extent of 3½ acres, one half of which is required for the electric lighting station; £850 to the Vestry of Rotherhithe for electric light installation, engine, boilers, &c., at their wharf in Rotherhithe-street; and £687 to the Vestry of Shoreditch for the enlargement of electric lighting station.—The recommendations were agreed to.

TRANSFORMER CHAMBERS.

The Highways Committee reported that the County of London and Brush Provincial Lighting Company had asked the Board of Trade to give a definite decision upon the appeals of the Company, which were the subject of an inquiry by the Board in December last. In February the Committee reported that the Board had intimated that it was not prepared to hold that sufficient reasons had been advanced, either on the ground of public safety or a want of Parliamentary sanction, to justify the Board in refusing to approve of a system of supply involving the use of transformer chambers in the public streets, and that the Board hoped that that decision on the general question would render unnecessary any further action on the appeals lodged by the Company. The Board afterwards approved a description of the supply under the County of London (North) Order, 1892, which contained the following words:—"The converting stations will be street boxes of sufficient size and suitable construction to contain several transformers, room being also provided to enable a man to enter the box and conveniently examine the transformer and controlling apparatus." The Council on April 9th and May 28th disapproved two notices given by the Company, each for the construction of the same 42 of these large chambers in St. Luke's and Clerkenwell, and doubtless that disapproval was the reason for the Company's request to the Board of Trade. The House-to-House Electric Light Supply Company had also appealed to the Board against the Council's disapproval on the Company's notice of the construction of one of these large chambers in Kensington. The Board of Trade had decided to hold a further inquiry into the matter, and the Committee recommended: "That the Highways Committee be authorised to take all necessary measures for making known at the Board of Trade inquiry the Council's objections to the transformer chambers being placed under the public streets, and for this purpose to employ counsel."

The recommendation was agreed to.

ELECTRIC LIGHTING FOR THE THAMES EMBANKMENT AND BRIDGES.

The report of the Highways Committee on the scheme for the lighting of the Victoria Embankment and the Waterloo and Westminster Bridges, which appeared in last week's *Electrician*, again came up for discussion.

Mr. Westacott said that, as they had all other matters to attend to, he would move that the matter be deferred.

This was seconded by Major Probyn, and carried.

The following notices of amendment have been given:—By Mr. Thornton, seconded by the Earl of Onslow: "That the Highways Committee be instructed to obtain reports from the engineer and the chemist upon the question whether the lighting of the Victoria Embankment and the bridges could be improved by the substitution of incandescent burners for those in use." By Mr. E. White: "That the recommendation be referred back to the Committee, with instructions to ascertain and report what is the cost of the present lighting, what would be the cost of incandescent gas lighting, and what would be the cost of electricity supplied by a company.

Digitized by Google

PHYSICAL SOCIETY.

At the ordinary meeting of this Society on June 28th, Dr. Gladstone (Vice-President) in the chair, Mr. BOWDEN read a Note on

"An Electromagnetic Effect."

A long glass tube containing mercury and fitted with a small standpipe to indicate the hydrostatic pressure, is passed between the poles of an electro-magnet. On passing a current of about 30 amperes through the mercury in this tube, the standpipe being turned so as to indicate the pressure either perpendicular or parallel to the lines of force of the field of the electro-magnet, movements of the mercury in the standpipe take place. When the standpipe is perpendicular to the lines of force of the field, the mercury rises or falls according to the direction of the current. When the standpipe, however, is parallel to the lines of force, the mercury always rises, whatever the direction of the current.

Prof. S. P. THOMPSON said there appeared to be three unexplained effects, one proportional to the current and the field and reversible, another independent of the direction of the current or of the field, and a third which only occurred while the current was changing in strength. In addition there might be a fourth effect which up to now had not been noticed. The motion of the mercury column was in the opposite direction to that of the drag on a conductor carrying the current. An apparent rise in the pressure might be due to a decrease in the density of the mercury, due to the heat developed by the current.

Mr. BLAKESLEY asked if the author had noticed any changes in level in the mercury reservoirs at the ends of the tube.

The AUTHOR, in his reply, said the reservoirs at the ends were so large that no changes of level were appreciable.

Mr. Rhodes read a Paper on

"The Armature Reaction in a Single-Phase Alternating-Current Machine.

In this Paper the author gives the investigations that were the subject of a verbal addendum to a Paper read before the Society on a previous occasion. He investigates the lag or lead of the E M.F.'s over the current, and applies the results to examine whether the field-excitation of the generator or the motor is strengthened or weakened by the reaction of the armature currents.

Mr. BLAKESLEY said that the conclusion of the author that "either of two alternate-current machines may be driven as a motor by the other, irrespective of their E.M.F.'s," was not invariably correct. The facts of the case were these : The E.M.F. of the motor might exceed that of the other machine to a certain extent, but that E.M.F., multiplied by the cosine of the angle of the electric lag, must yield a product not greater than the E.M.F. of the generator—*i.e.*, using Mr. Rhodes's symbols, $e \cos \theta$ must not be greater than E. Mr. Blakesley gave a geometrical proof of this, but the same proposition had been given by him some ten years ago in the course of investigating the subject generally. This was at a time when Dr. John Hopkinson was, with less than his usual perspicuity, teaching that synchronous alternate-current machines could not be run in series with stability, both doing work. Referring to the author's diagrams, Mr. Blakesley said that in a problem involving so many elements as that under consideration it was impossible, with the limited dimensions of space, to represent the results with the complete generality of a formula. Some elements had to be taken as the independent, others as the dependent variables. The author had considered the power transmitted to the motor, the E.M.F. of the generator and the angle of electric lag as independent. The E.M.F. of the motor was dependent. In Mr. Blakesley's original diagrams the E.M.F.'s were both considered independent, as well as the electric lag, and the powers applied or transmitted as dependent variables. In any case the formulæ properly derived from such diagrams became perfectly general, and it did not appear to him that the change of method indicated could properly be called a new theory on the subject. As a matter of fact, diagrams based on the independence of the E.M.F.'s and the electric lag would furnish a better means of discussing the question of the stability of the motion than Mr. Rhodes's plan, and this might account for the entire omission from the Paper of this important matter.

Prof. S. P. THOMPSON said it was impossible to discuss the question of stability till the subject of armature reaction had been thoroughly investigated. The terms, lag and lead, had been used by Mr. Rhodes in a consistent manner, but this was not always done, and he recommended that the phase of the current which was common to both generator and motor be taken as the standard.

The AUTHOR, in his reply, said he agreed with Mr. Blakesley that there was a limit to the extent to which the motor might be excited, and this upper limit could easily be obtained from the figure given in the Paper. The question of armature reaction was, however, most important, as it might excite the field two or three times more than the original excitation. Since motors were designed to do a certain amount of work, and not the work to fit the motor, it was most natural to take the output of the motor as fixed.

Mr. SHELFORD BIDWELL read a Paper on

'The Electrical Properties of Selenium.'

The author has continued his investigations on this subject, and has come to the following conclusions:—(1) The conductivity of crystalline selenium appears to depend principally on the impurities which it contains in the form of metallic selenides. It may be that the selenides conduct electrolytically, and that the influence of light in increasing the conductivity is to be attributed to its property of facilitating the combination of selenium with metals in contact with it. (2) A selenium cell having platinum electrodes, and made with selenium, to which about 3 per cent. of cuprous selenide has been added, is, even though unannealed, greatly superior, both in conductivity and sensitiveness, to a similar cell made with ordinary selenium and annealed for several hours. (3) Red selenium in contact with copper or brass is quickly darkened by the actions of light, owing, it is suggested, to the formation of a selenide. (4) Crystalline selenium is porous, and absorbs moisture from the air, and it is this moisture that causes the polarisation of selenium after the passage of a current. (5) The presence of moisture is not essential to sensitiveness, but appears to be in a slight degree favourable to it. (6) If cuprous selenide is made the cathode in an electrolytic cell, and a strip of platinum the anode in water, red selenium, mixed with detached particles of the selenide, is deposited in the water. (7) The photo-electric currents, sometimes set up when light falls upon selenium, are dependent upon the presence of moisture, and are no doubt of voltaic origin. (8) Perfectly dry selenium is below platinum in the thermo-electric series.

Prof. MINCHIN [communicated] suggested that selenium "cell" should be called a selenium "resistance." A grid having one terminal made of aluminium and the other of copper might form a true cell, and might generate an E.M.F. when light fell on it. He (Prof. Minchin) would like to know if the author had tried any such cell in which light simply and solely generated an E.M.F. He could not argue that chemical action must necessarily follow the action of light in a cell; for take the case of the oldest photo-electric cell, the thermopile, what chemical action can we show there for all the energy of the incident heat ? Chemical action, due to light, may or may not occur, according to the nature of the cell.

Mr. APPLEYARD asked whether the author had submitted these selenium resistances to the action of electric oscillations. Prof. Minchin's "impulsion" cells were greatly influenced by electric oscillations. The great variation in the resistance with time of the author's cells pointed rather to an effect of contact between the selenium and the electrodes than to an elementary change in the structure or composition. He (Mr. Appleyard) had recently tried to crystallise a supersaturated solution of sodium sulphate by electric oscillations, as well as by direct sparks, and by currents of several amperes, but no crystals could be induced to form. Change of contact, rather than change of structure, appeared to him to be the most promising direction in which to look for an adequate theory of selenium resistances.

Prof. RAMSEY said the quantity of selenium liberated in the electrolytic experiment was much too great to be accounted for by oxygen dissolved in the water. The study of selenium was very interesting, for this substance was in the borderland between those bodies in which the electric conduction was metallic and those in which it was known to be electrolytic.

The AUTHOR, in his reply, said he agreed that the name "selenium cell" was not an appropriate one. He had not tried the effect of electric oscillations.

The Society then adjourned till the autumn.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *July 6, 1895.*

The Niagara Plant.—The first public exhibition of the machinery of the Niagara electrical transmission plant was given last week before the members of the American Institute of Electrical Engineers in attendance at the annual general meeting of that body at Niagara Falls, and the opinion of the 150 or more engineers was unanimous that the plant is an unqualified success. One of the 5,000 H.P. units was in operation, and was run from no load to 5,300 H.P., and the load rapidly varied by large amounts without the slightest noticeable change in performance. The steel field cylinder surrounding the armature weighs, with its magnets, 40 tons, and revolves at 250 revolutions per minute, giving a peripheral velocity of over 9,000ft. per minute. So excellent has been the mechanical execution that at a short distance the machine appears to be at rest, and no tremor is noticeable upon close inspection when large variations in load are rapidly occurring. One of the most interesting parts of the apparatus is the hydraulic governor, furnished with the turbines by Messrs. Faesch and Piccard, of Geneva. During the time of the visiting engineers in the power house the loads were constantly varied, and the operation of this beautiful piece of machinery was watched with the most lively interest. The vertical shafting, 140ft. in length, also attracted much attention. As your readers are doubtless aware, this shafting consists of hollow steel cylinders or tubes, 38in. in diameter, with short lengths

Digitized by Google

of solid shafting 11in. in diameter at the three bearings, and so well has it been constructed and aligned that the cylindrical portion was frequently mistaken for the turbine flumes, which, however, are 7ft. in diameter. Visitors to the turbine pit were almost deafened by the intensely shrill noise, which was, presumably, caused by the impact of the water on the buckets of the turbine; the note was extremely disagreeable and penetrating, and rendered the hearing of speech in the pit almost impossible. While no tests have yet been made public, it is said that the efficiency of the turbine approaches 79 per cent. Not a hitch has occurred in the operation of the dynamo, which has been run experimentally at frequent intervals for some time, and on the last day of the meeting 2,000 H.P. were transmitted to the rotary transformer plant of the Pittsburgh Reduction Company, whose performance was similarly satisfactory. In an address delivered before the Institute at Niagara, Mr. Coleman Sellers stated that from the inception of the enterprise no mistake worth mentioning had occurred, and while the extremely conservative policy of those at the helm had much to do with the signal success achieved, yet the engineers who designed and carried out the work might well be proud of what perhaps may be considered one of the most admirable engineering achievements of the age.

The Niagara Meeting of the American Institute of Electrical Engineers.—The twelfth annual meeting of this Institute was the most successful one in its history, the attendance of the members and guests being over 200. Of the 16 Papers read the inaugural address of the President, Dr. Duncan, easily takes first rank, and is besides a contribution of most timely importance in view of the vague notions at present held as to the probable scope of electric traction. The conclusions of Dr. Duncan on this point are that it would not be advisable to substitute electricity for steam in moving heavy freight, nor on tracks over which widely-varying classes of traffic pass. The address was considered rather conservative by some of the more enthusiastic electrical engineers, but the arguments were apparently so well founded that no one attempted any material criticism. Mr. C. P. Steinmetz read two strong Papers; in one the mathematical theory is developed of what is called a general alternating current transformer, which includes the stationary transformer and induction motor as special cases. In another Paper a review of the work done in the last several years in alternating currents is given, and a new system of nomenclature proposed for alternating currents. It is suggested that the name of "polycyclic" be given to other than simple alternating systems, and that a factor be applied to the different systems to designate the balance; according to this the "monocyclic" system would be a "polycyclic" system with a balance factor of zero, and a three-phased system with both sides equally loaded a "polycyclic" system with a balance factor of one. It is interesting to know in this connection that a patent has recently been issued to Mr. Steinmetz for a "polycyclic" system. Prof. F. B. Crocker read a Paper on the application of electric power in factories and mills, giving a large quantity of data giving the amount of power required to drive all the usual machine tools. In a Paper by Mr. Franklin L. Pope an account is given of the transformation at a very moderate expense of an unprofitable town lighting system into a dividend-paying property with the latest types of apparatus. The 10,000 volt Pomona, Cal., plant was described by Mr. G. H. Winslow. This consists of two 120-kilowatt alternators, the energy of which is transmitted to two towns at distances of 13¾ and 28¾ miles, respectively, over No. 7 copper wire. The regulation is accomplished at the generating station; at the two sub-stations, from which the current is distributed, the plant is started up in the afternoon by a clerk and the stations then locked up until the next morning. The plant has been in operation three years and no difficulty whatever has been experienced. An excellent Paper was read by Mr. C. E. Emery giving the yearly cost of steam power in units of 20,000 H.P. He finds that with coal at $2.24 per ton, and for a consumption of 1·25lb. of coal per indicated horse-power per hour, the cost of steam power would be $23.13 for 10 hours on a basis of 20,000 H.P. delivered continuously with 10 per cent. on original cost of plant charged for dividends, and $0.75 per horse-power added for general business expenses.

The English Westinghouse Company.—In the report of the Westinghouse Electric and Manufacturing Company, just issued, it is announced that the parent Company during the past year sold additional patent rights to the English Westinghouse Electric Company (Limited), and with the proceeds purchased Preferred and Common Stock of English holders, so that it now holds $782,500 Preferred Stock, and $1,307,400 Common Stock out of $2,322,750 outstanding, and the parent Company will hereafter direct all of its affairs. All apparatus sold by the London Company has been purchased from the parent Company, it is stated, at profitable rates, and the business of the former has always been profitable; last year it netted, the report states, nearly 5 per cent. on a valuation of $1,000,000. The report adds that the management intends to continue to push business in Great Britain, Continental Europe, and the various Colonies, in order to increase sales of Westinghouse apparatus, and that it is believed that the new prices which will be made to the London Company will enable it to largely extend its sales, and give a permanent value to all of the stock now held by the parent Company.

CORRESPONDENCE.

AMERICAN PRIORITY IN TELEGRAPHING WITHOUT WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The above is the heading under which Prof. Dolbear's letter, which you reproduced in *The Electrician* of June 21st, appeared in the *Electrical Engineer* of New York, U.S.A. May I beg of you to afford me the opportunity of saying a word or two about it?

Nearly fifty years ago, and thirty years before Prof. Trowbridge "made original researches between the Observatory at Cambridge and the City of Boston," your humble servant, the writer of these lines, had also researched on the same subject, and a year or two later published the results of his investigations in an English periodical—the *Mining Journal* of March 31, 1849—under the heading "Telegraph communication between England and France." In that letter, after going into the subject very much like the American Professor in 1880, there will be found my explanation—also not differing much from the Professor's—as to how the thing was to be done; except that, in my case, I proposed a new and delicate form of galvanometer or telegraph instrument for the purpose, while he made use of the well-known telephone. I suggested the erection of lengths of telegraph wires on the English and French coasts, with terminals dipping into the earth or sea, and as near parallel as possible to one another; and I suggested a form of telegraph consisting of "coils of finest wire, of best conductibility," with magnets to deflect them, on the passage of a current of electricity through them, which I expected would take place on the discharge of electricity through the circuits on either side of the water; anticipating, of course, that a portion of the current would flow from the one pair of earth-plates—terminals of one circuit—to the other pair of terminals on the opposite shore. This appears to me to be just about what Prof. Trowbridge proposed to effect, and which Prof. Dolbear says "covers the ground of doing telegraph work by means of earth conduction." If I should be mistaken, would Prof. Dolbear please show me where I missed it? and, as I am proposing to contend for its English origin, I don't see why I should not at the same time claim for myself "whatever of merit or utility there may be in this method of telegraphy without wires"—especially as Prof. Dolbear also says that "it is a discovery, and an important one too," which I now am induced to believe—seeing that he says it is so.

But, Mr. Editor, after all, I don't value at one finger-snap the circumstance that I happened, so early as the year 1849, to suggest a possible mode of telegraphing without wires, and of which, most likely, Prof. Dolbear was ignorant; it is only the apparatus by which I obtained the signals in experiments I made to this end, to which I attach the least importance. In

Digitized by Google

a footnote to my letter which appeared in the *Mining Journal* it will be seen that I laid "claim" to a conjunction of coils of wire to convey electricity, with magnets, for the purpose of deflecting them as an original form of "telegraph" working with "the least amount of current and resistance," and "depending much upon the power of the magnets," as a "design or invention of my own." Later on, I will show why I attach importance to the above.

It may interest your readers, perhaps, if I tell them how I came to think that "telegraphy without wires" was a possibility, and that it should have appeared to me to have some value at a time when gutta-percha as an insulator was not imagined, or the ghost of a proposition for a submarine wire existed. At that time, too, it was with the utmost difficulty that efficient insulation could be maintained in elevated wires if they happened to be subject to a damp atmosphere.

It was in the year 1845, and refers to the one only long line of telegraph then existing in England—London to Gosport—which induced me to refuse the accepted theory that currents of electricity discharged into the earth at each end of a line of telegraph sped in a direct course—instinctively, so to say—through the intervening mass of ground to meet a current or find a corresponding "earth-plate" at the other end of it to "*complete the circuit.*" I could only bring myself to think that the earth acted as a reservoir or condenser—in fact, receiving and distributing electricity almost superficially for some certain or uncertain distance around the terminal "earths," and that according to circumstances only. A year later, while occupied with the installation of telegraphs for Messrs. Cooke and Wheatstone (afterwards the Electric Telegraph Company), a good opportunity offered of testing this matter practically upon lengths of wire erected on both sides of a railway. To succeed in my experiment, and detect the very small amount of electricity likely to be available in such a case, I evidently required the aid of a very sensitive galvanometer, much more so indeed than the long pair of astatic needles and coil of the Cooke and Wheatstone telegraph, which was then in universal use as a "detector." The influence of magnetism upon a wire conveying an electric current at once suggested itself to me, and I constructed a most sensitive instrument on this principle, by which I succeeded in obtaining actual signals between lengths of elevated wires about 120ft. apart. This, however, suggested nothing more at the moment than that the current discharged from the "earth-plates" of one line found its way into the "earth-plates" of another and adjacent circuit, through the earth. Later on, I had other opportunities of verifying this matter with greater distances between the lines of wire, and ultimately an instance in which the wires were a *considerable distance apart*, and with no very near approach to parallelism in their situation. Then it was that it entered my head that "telegraphing without wires" *might be a possibility.*

However, to cut a long story short—whether this sort of telegraphy depended upon the earth passage or induction through the atmosphere Prof. Dolbear seems to think the discovery of it to be "meritorious," and I think it is only fair that I should ask for "whatever merit" happens to belong to it—by reason of "*priority.*"

There is just one other item connected with it all which I may be pardoned for introducing now, and that is: In the year 1849 I published, and claimed as a "design or invention of my own," a certain form of instrument which I actually made and used, not only in England, but in North America, in the year 1851, in the interest of a Mr. Henry O'Rielly and others, and which turns out to be the only thing applicable or possible to be availed of in the accomplishment of recording signals in ocean telegraphy—even at the present day.

With reference to the rather significant suggestion of Prof. Dolbear that Prof. Trowbridge's efforts in the direction of "telegraphy without wires" have been "forgotten or ignored," what might I not now retort? But it is not to be expected that everyone shall get to know what everyone else has done in any particular direction, especially when so many years have elapsed, and perhaps before they were born, or could read for themselves or ever were in a position to see the accounts of what others had done in print. This holds good, too, with reference to the form of instrument I claimed in the *Mining Journal* of 1849, when I know for certain that the same design has been patented at least twice in the United States, the last time within a year or two, and illustrated and described as a new invention in the pages of the *Electrical Engineer* of New York. How was that last patentee, or the patent officials at Washington, to know that the *invention* under consideration was common property, and was well known to scores of persons in the United States near half-a-century ago?

Fifty years ago, Mr. Editor, I took charge of the telegraph on the Northampton and Peterboro' Railway on the opening of that line, July 1, 1845. I had then been under the personal training of Mr. W. F. Cooke for three months in the establishment of Robert Reid, the original maker of telegraphs; and I don't think I need be ashamed of suggesting that I may possibly be—if not the oldest—at least the *first* in this country who ever qualified, by a course of practical and theoretical instruction, under competent teachers (of all that was to be acquired at that day), with the object of following the profession of electric telegraph engineer.

Trusting you may insert this letter, although it is very long, and that it may come to be seen that "priority in telegraphy without wires" belongs to this side of the Atlantic and not the other, if no more, and I shall be quite satisfied with the result.—I am, &c.,

J. W. WILKINS.

ARC LAMP GLOBES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On p. 345 of your last issue you refer to a case in which the carbons of an arc lamp were burnt through when used in connection with a spherical silvered globe. It may perhaps be of interest to some of your readers to hear that the use of silvered globes is not at all necessary to produce this effect.

About two years ago, during the trial of a large installation of arc lamps, several of the negative carbons burnt through about an inch above the holder. Egg-shaped opalescent globes were used, and these being elliptical at the top gave such well-defined foci that in some cases I was able in a few seconds to blacken a splinter of wood introduced through the bottom of the globe.

By increasing the size of the negative carbon the C^2R losses were diminished, and the temperature of the carbon sufficiently reduced to prevent its burning.—Yours, &c.,

Chelmsford, July 16, 1895. E. A. N. POCHIN.

LEGAL INTELLIGENCE.

Direct Spanish Telegraph Company (Limited) v. the Owners of the "Caloric."

This action came before the Appeal Court (the Master of the Rolls and Lords Justices Kay and A. L. Smith), with nautical assessors, on Monday last, being the appeal of the plaintiffs against the judgment of Mr. Justice Day in March last. It will be remembered that the case for the plaintiffs was that in November, 1894, the "Caloric," while on a voyage to Bilbao, improperly anchored in a place where the plaintiff Company's submarine telegraph cable was lawfully lying; that she neglected to move therefrom; and refused to take the assistance of a pilot, in contravention of the rules and regulations of the port and harbour of Bilbao, and allowed her anchor to foul and become entangled with the cable; that the defendants' servants negligently or unnecessarily caused the cable to be cut and damaged, and that thereby the plaintiffs suffered loss. The defendants denied that the plaintiffs suffered damage as alleged, and alternatively they said that if the "Caloric" fouled the cable, such fouling was occasioned by the "Caloric" while properly lying at anchor in a proper anchorage ground, encountering a gale of exceptional violence accompanied by terrific squalls, whereby she was driven across the track of the cable; that the cable was not properly buoyed or marked; and that the defendants' servants had no knowledge of and no reason to anticipate the presence of the cable at or about the place of the ship's anchorage. Though the question of whether the captain of the "Caloric" anchored in the right place was the first one in dispute, much of the argument in the original action turned on the point whether the captain ought not to have slipped his anchor when he found that the vessel was entangled in the cables, of which there were two in his place of anchorage. One of these broke through the strain, and the other was cut to get the vessel free from entanglement. The plaintiffs' nautical witnesses said that the

Digitized by Google

captain ought to have slipped his anchor; but he and other nautical witnesses for the defendants said that he took the proper course to get rid of the cables. One of the subjects in dispute was which cable he cut. Of the two cables, one—the new one—belonged to the plaintiffs. The old one was the property of the Spanish Government. The contention of the plaintiffs was that theirs was the one cut, that of the defendants that it was the old one which was cut. Defendants' counsel maintained that plaintiffs had not suffered any damage through the action of the defendants' employés. Mr. Justice Day, after consulting with the assessors, came to the conclusion that there was no negligence, and further, was not satisfied that the plaintiffs' cable was cut in the way suggested. Judgment was therefore given for the defendants with costs. The plaintiffs now appealed.

Mr. A. COHEN, Q.C., for the plaintiffs, said the injury was done to the cable by reason of the steamer fouling the cable.

The MASTER of the ROLLS (to Mr. Cohen): Do you say that an accidental fouling of a telegraph cable by a ship is actionable?—Certainly not. But in this case it was seen for at least half an hour that this ship was really hanging on to this cable with its anchor.

Lord Justice SMITH: Then do I understand that the first foul would be accidental, and that it was the hanging on that was negligent?—Yes.

The MASTER of the ROLLS: What is the ground of the appeal? Do you say that the Trinity Masters advised the Judge wrongly on the question of seamanship? They advised him that the captain acted as a prudent and reasonable man would have done. You say that they advised the Judge wrongly.

Mr. COHEN submitted that the advice of the Trinity Masters was inconsistent with the facts and the evidence.

The MASTER of the ROLLS called attention to a portion of Mr. Justice Day's judgment, which ran: "The course taken by the captain was a reasonable course, and the captain was quite justified, as a matter of seamanship, in endeavouring first of all for a reasonable time to get the cables clear without slipping his anchor." His Lordship also referred to another portion of the judgment: "The master acted prudently, and not negligently."

Mr. COHEN submitted that the cable was lawfully there, and that the master was negligent in allowing his vessel to hang on to the cable for half an hour.

The MASTER of the ROLLS said the master did not know he was hanging on to a cable. He did not know where this beastly serpent was!

Lord Justice SMITH added that the Judge had said that there was no reason to doubt the accuracy of the master's statement that he (the master) was not aware of the existence of a submarine cable.

Mr. COHEN was referring to the Submarine Telegraph Act, 1885, when the Master of the Rolls interposed with the remark: "A master of a ship does not know anything about Acts of Parliament, and he is not bound to sit down and read Acts of Parliament."

Mr. COHEN: If he violates the provisions of an Act of Parliament his owners are liable. The master ought to have taken care not to injure the property of others.

The MASTER of the ROLLS: How can he take care if he does not know of its existence? If the master had slipped his anchor it would have gone down to the bottom and been entangled in the cable just the same as before. This telegraph cable was lying there without anything being put there to give notice of its whereabouts.

Without calling upon respondents' counsel, the MASTER of the ROLLS said the appeal must be dismissed. Here the captain found himself, it must be admitted, in a difficult position. It was all very well to say that the captain ought to have sacrificed his owner's property in order to save the property of somebody else. The only question here was, Did the captain do anything which a captain by ordinary care and skill would not have done, and did he omit to do anything which a captain by ordinary care and skill would have done? The learned Judge in the Court below was advised by his nautical advisers that neither of these propositions could be made out against the captain, and the gentlemen who advised them (the Appeal Judges) were of the same opinion. Therefore, although the case was very well put by the plaintiffs' counsel, both Courts were of the opinion that there was nothing like negligence of any kind, and of course if that were so the action could not lie.

Lords Justices KAY and SMITH concurred, and the appeal was accordingly dismissed, with costs.

Corporation of Portsmouth v. Edwards.

This action, which was decided last week at the Portsmouth County Court, was for the recovery of £5 for electric current supplied by the Portsmouth Corporation to a local tradesman. The defence was that the meter which registered the consumption was unreliable, and that the number of units consumed was not so great as recorded. After hearing evidence, the Judge held that the expert evidence favoured the defendant's contention, and he gave judgment for him.—Mr. King (on behalf of the plaintiffs) asked for an adjournment, in order that he might apply for leave to appeal, as the finding was a serious matter for the Corporation.—Mr. Burbidge (for the defendant) argued that Mr. King could not appeal on a question of fact, and in this view his Honour concurred, but said that of course the Corporation would move for a new trial.

Muirhead v. The National Electric Supply Company (Limited).

Lords Justices LINDLEY, LOPES and RIGBY, in the Court of Appeal on Wednesday last, directed that there should be a new trial in the case of Muirhead v. the National Electric Supply Company (Limited), which was tried before Mr. Justice Day in the Queen's Bench Division on May 25th last.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

SPECIAL NOTICE.—The 1895 (thirteenth) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. In addition to the old well-known features of the book, which are brought up to date, a quantity of new and useful matter has been added, rendering the book more than ever indispensable to the Electrical, Engineering, and Allied Trades. Price, 7s. 6d., post free 8s. 3d., abroad 9s.

The following New Books and Editions of "THE ELECTRICIAN" SERIES *can be obtained of the Booksellers or direct from the Publishing Offices:—*

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett (*now ready*). Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

A LARGE-SHEET TABLE, giving full particulars of the Electricity Supply Stations throughout the Kingdom, can now be supplied mounted on stout board, with cord for hanging. Price: Varnished, 3s. 6d.; Unvarnished, 3s. —each post free. A Map showing positions of Supply Stations throughout the country is mounted on the back of the Table, and a Coloured Map of Metropolitan Electric Lighting Areas and a large sheet of Electricity Supply Statistics are also mounted on some copies, the price of which complete, post free, is 5s.

A SHEET TABLE showing Total Capital Outlay and Receipts and Expenditure for the year 1894 of the Statutory Electric Supply Undertakings of the Metropolis is now ready, printed on thick paper, price 6d. each.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—By Mr. F. Marten Weymouth, is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson, price 6s. 6d., post free.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell, with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d. post free.

TENDERS INVITED.—The Corporation of Brighton require tenders for the supply and erection, at their electricity works, North-road, of evaporative brass tube surface condensers, electrically-driven air pumps, and exhaust and condenser pipings. The specification can be seen at the office of Mr. F. J. Tillstone, Town Clerk, Town Hall, Brighton, to whom tenders must be sent before 10 o'clock on Saturday, August 10th.

——— The Salford School Board invite tenders for the installation of the electric light in their new offices in Chapel-street, Salford. Plans and specifications may be obtained from Mr. S. V. Clirehugh, Temple Chambers, Brazenose-street, Manchester, on and after Tuesday next, the 23rd inst. Tenders, addressed to the Chairman of the Board, must be in by 12 o'clock on Wednesday, July 31st. Additional particulars may be obtained from our advertisement columns.

——— The Crown Agents for the Colonies require tenders, to be delivered by 11 a.m. on Thursday, August 1st, for the supply of materials in connection with the installation of the electric light in the Civil and War Department buildings at Malta. The materials required comprise cables and wires, tools, &c., fittings, fixtures, &c., and sundries.

——— Tenders are invited by the Vestry of Hammersmith, London, W., for complete schemes for public and private lighting, and for the supply of motor power in the compulsory area of the

Digitized by Google

Vestry's Provisional Order. Some particulars are given in our advertisement columns, and all further information can be obtained of Mr. H. Moir, Surveyor to the Vestry. Tenders have to be sent in by 6:30 p.m. of Wednesday, September 4th.

Tenders Invited.—The Electric Committee of the Belfast Corporation invite tenders for the construction of street culverts, supply of cast-iron pipes and frames, insulators, insulated cable, copper strips, &c., required by the department for one year. Tenders, addressed to the Town Clerk (Sir Samuel Black), Town Hall, Belfast, must be in by Wednesday next, the 24th inst. Our advertisement columns contain additional information.

——— Tenders are invited by the municipal authorities of Biar, Spain, for the concession for lighting the public streets by electricity for five years. Tenders to the Secretaria del Ayuntamiento, Biar (Alicante), Spain.

——— Tenders are required by the 26th inst. by the Dutch Minister of Waterways, Commerce and Industry for (1) the erection of and repairs to telegraph lines between Haarlem and Rotterdam, and (2) in Brabant, Limburg and Gelderland. Tenders to the Minister, at the Hague.

——— The Shropshire Iron Company (Limited), Wellington, Salop, require tenders for a complete electric lighting plant for their works lighting.

——— The Town Council of Whitehaven require tenders for electrical fittings, incandescent lamps, &c., for the year ending July 31, 1896. Tenders must be sent in to the Town Clerk, Whitehaven, by the 26th inst.

——— The District Council of Cowes (Isle of Wight) require tenders for the erection of electrical plant. The tenders have to be sent in to Mr. Damant, High-street, Cowes, before August 27th.

Tender Accepted.—The Hanley Town Council have accepted the tender of Mr. Cornes for the erection of additional buildings required at the electricity works.

Plant for Sale.—The Woolwich District Electric Light Company have two Davey Paxman boilers, two "Bennis" mechanical stokers, with shafting, pulleys, &c., and a 3 h.p. electric motor for disposal. Applications should be sent to Mr. G. E. B. Pritchett, 31, Soho-square, London, W. Further particulars appear in our advertisement columns.

Appointments Vacant.—The Tunbridge Wells Borough Council are prepared to receive applications for the appointment of an assistant electrical engineer. Salary £100 per annum. Applications must be in by the 24th instant. Our advertisement columns contain additional particulars.

——— From our advertisement columns it will be seen that the St. Pancras Vestry (London, N.W.) require two assistant electricians for their electricity and refuse destructor works at King's-road. Salary £100 per annum. Applications, addressed to Mr. Albert E. Pycraft, Chief Clerk, Electricity and Public Lighting Department, Vestry Hall, Pancras-road, N.W., must be in by Tuesday next, the 23rd instant.

——— The Governing Body of the Northampton Institute, Clerkenwell, E.C., are prepared to receive applications for the appointment of a principal. The salary attached to the office has been fixed at £600 per annum, and the duties will commence on January 1st next. Applications must be sent in, before 10 a.m. on September 4th, to the Clerk (*pro tem.*), Mr. J. J. Lambert, 8, Dowgate-hill, Cannon-street, London, E.C. Some further particulars appear in our advertisement columns.

——— The University College of South Wales and Monmouthshire require an assistant lecturer and demonstrator in engineering. Applications should be sent to the Registrar and Secretary (Mr. J. A. Jenkins, B.A.) by August 31st next. Further information is given in our advertisement columns.

Appointment.—Mr. O. V. Thomas, who was for some years at Singapore, some time back joined the Eastern Extension Telegraph Company's service, and was lent by that Company to the Government of British North Borneo. Mr. Thomas has now been gazetted Superintendent of Telegraphs to the British North Borneo Government.

Personal.—It will be seen from the report of the Directors of the National Telephone Company that Lord Balfour of Burleigh (Cabinet Minister in Lord Salisbury's administration) and Col. R. R. Jackson (owing to ill-health) have resigned their seats at the Board of the National Telephone Company.

Bankruptcies.—A meeting of creditors under the failure of J. Torr Todman, electrician, late of 11, Queen Victoria-street, and 36, Bermondsey-street, London, was held last week. The insolvency is attributed to liability on accounts guaranteed by the bankrupt as managing director of a company, and on accommodation bills for which he received no consideration. A proposal was before the meeting to pay a composition of 7s. 6d. in the pound by three instalments of 2s. 6d., the cash to pay the first to be deposited with the official receiver before the Court was applied to for its approval of the arrangement, and the second and third instalments, payable at six and nine months from the date of approval, to be secured by the joint and several promissory notes of the debtor and his mother. The offer was not accepted, the case being left in the hands of the official receiver.

Bankruptcies.—A Receiving Order has been made against the estate of Ronald A. Scott, described as an electrical engineer, The Elms, Acton Hill, Middlesex.

Catalogue.—We have received from Messrs. H. M. Salmony and Co., of Charing Cross-road, London, W.C., a very complete catalogue of electrical sundries. Amongst other items we note silvered-reflector glow lamps which are claimed to be far less liable to peel than the ordinary run of silvered bulbs; cut-outs with diverging contact plates, which thus allow the use of longer fuses than do other cut-outs of the same size, and a simple gravity-action pattern arc lamp. Messrs. Salmony also sell arc lamps and battery carbons, a special style of carbon brush, Arnoux-Chauvin ammeters and voltmeters, dry batteries, &c.

Journalistic Enterprise.—We have to acknowledge the receipt of another summer number of the *Western Weekly News*. Mr. Ernest Croft, the energetic manager of the *News*, is to be congratulated upon his latest attempt to cater for the holiday public. The illustrated description of Western holiday haunts should prove an excellent advertisement for these beautifully-located health resorts.

A Successful Experiment.—"We (*Sheffield Daily Telegraph*) have just completed an interesting experiment, and, as the results may be of use to our readers, we have pleasure in giving details. Owing to the number of engines in and about our basement, we were troubled with great heat, which non-conducting material, electric ventilating fans, and open windows failed to diminish. Much of this heat proceeded from pipes conveying steam from the boilers to the various engines. As we have a dynamo running night and day for lighting purposes, we decided to try electric motors instead of engines, and shut off the steam entirely from all steam pipes. Two motors have been running for the last eight weeks, and the temperature has been greatly reduced. The motors are also an improvement on steam engines, as they are cleaner and noiseless in working. The most satisfactory feature, however, is the economy of electricity. We have most carefully examined our coal consumption, and have had the figures checked, as we did not expect any saving, but the fact remains that we are burning six loads per week less than before the motors were introduced." The *Sheffield Daily Telegraph* offices are amongst the finest blocks of newspaper premises in this country, and such testimony to the suitability of electric motors for newspaper printing work is of the very highest value. The avoidance of noise is in itself no mean recommendation, and the large printing works in the neighbourhood of Fleet-street, London, should prove eager customers for electric motor plant.

British North Borneo.—In reference to the appointment of Mr. O. V. Thomas, mentioned elsewhere, the telegraph line now being constructed for the Government of British North Borneo by Mr. Thomas is overland from the main land opposite Labuan to Sandakan, which country is unexplored, but Mr. Thomas has hopes that the line will be completed within a year.

Fires.—We regret to announce that the works of the General Electric Company, at Chapel-street, Salford, were destroyed by fire on Friday night last. The whole of the five-storey building was gutted. The fire originated on the ground floor, and was difficult of access, and, as a strong wind was blowing, fears were entertained that, notwithstanding the heroic efforts of the firemen, the fire would not be confined to the General Electric Company's premises. Ultimately, however, success attended the firemen's efforts, and little other damage was done. The loss is variously estimated at from £20,000 to £30,000! We are asked to state that the General Electric Company's business will be in no way interfered with, and that orders will be executed with the usual promptitude from heavy stocks in London, Manchester, and Glasgow, as well as from the manufacturing facilities that the Company possess at their various works and shops at Hammersmith, Clerkenwell, Thames-street, &c. New works have been taken at Adelphi, Salford, for which plant, machinery, and tools are now being prepared, and which, when completed, will enable the Company to increase their output considerably.

——— Singularly, another fire broke out on Saturday at Messrs. W. T. Glover and Co.'s works, Springfield-lane, Salford. The fire was discovered in one of the large sheds, and is supposed to have been caused by the overflow of one of the tanks containing composition for cable covering. Owing to a plentiful supply of water being available, the firemen experienced little difficulty in dealing with the conflagration. In this case it is estimated that £1,000 will cover the damage, and the many friends and customers of Messrs. Glover and Co. will be pleased to learn that only one department of the business is affected by the fire, and that all work

Digitized by Google

is being carried on as usual and without any delay. The citizens of Salford are certainly to be congratulated upon the efficiency of the fire brigade, as at both these fires property of great value was in jeopardy, and was only saved from destruction by the energetic and successful efforts of the brigade.

CALCUTTA.—An interesting article in a Calcutta exchange points out that, notwithstanding that the City claims to rank fifth in importance amongst the cities of the world, and can at any rate claim to be one of the hottest, the streets, offices and residences of the citizens are still lighted by gas or paraffin, and the electric light is practically unknown. The journal asks why, in the name of all that is practical, economical and progressive, is not the electric light in general use in Calcutta.

CARDIFF.—At the meeting of the Electric Lighting Committee, on Tuesday last, it was agreed that, as the estimated cost of the electric works and plant (£32,500) had been exceeded by £5,000, an additional £7,500 should be borrowed to meet that and other extra expenditure. At the same meeting the borough engineer submitted an estimate of the working expenses of the lighting department (including gas and electricity) for the next six months, the total amount being £5,380. 10s., against £5,580 for the previous half-year.

DOUGLAS (ISLE OF MAN).—The Isle of Man Tramways and Electric Power Bill has been the subject of a petition from the Douglas Town Commissioners to the Tynwald Court Committee. Two schemes are before the Isle of Man authorities, one for the erection of a cable line, and the other for an extension of the present electric tramways. A very liberal offer has been made by the Tramways and Electric Power Company to pay a minimum of £1,500 a year, or 15 per cent. on the gross takings, for the extension of the lease of the shore line for 20 years, and they undertake to construct and work a tramway to Upper Douglas. Some opposition to both schemes was presented, and the Committee adjourned to further consider the matter.

DUBLIN.—A meeting of the Dublin United Tramways Company was held on Tuesday, at which, after declaring a dividend of 5 per cent., the Chairman referred to the subject of electric traction for their lines. The Company's Bill before Parliament was supported by the Town Commissioners of Clontarf, Drumcondra, and Kilmainham, as well as by other important interests in the districts through which their tramways pass, but opposition was offered by the Dublin Corporation and the Commissioners of several of the districts, which necessitated their omitting Dublin City and the townships of Rathmines and Pembroke from the operations of the Bill. The Chairman pointed out that the opposition of the Dublin Corporation was, he thought, owing to a misunderstanding, as the Company were most desirous to meet the Corporation, and to maintain friendly relations. The Company proposed to proceed to construct the line from Dollymount to the boundary of the city, and to be ready by next spring. As evidence of the strong local wish for the electric line the Company had secured signatures from 370 out of a possible 385 frontages on both sides of the line.

EDINBURGH.—The Cleaning and Lighting Committee of the Town Council have decided to recommend that George-street and the various side streets therefrom to Princes-street be lighted by electricity.

FULHAM (LONDON, S.W.).—The Electric Lighting Committee have presented a further report on the lighting of the district by electricity, which states that there are reasonable grounds for supposing that a combined electric lighting and dust destructor scheme could be installed and worked at a profit to the ratepayers. Messrs. Kincaid, Waller and Manville have therefore been asked to prepare a report at a fee of £50. The Capital and Counties Electricity Supply Company have given the Vestry notice of their intention to apply for an electric lighting Provisional Order. The Committee recommend that the application be opposed.

HALIFAX.—Major F. H. Tulloch, M.I.C.E., will hold an official inquiry to-day (Friday) into the application of the Corporation for sanction to borrow £10,000 for electric lighting purposes.

HARROGATE.—At the last meeting of the Town Council it was resolved to wire the Montpellier Baths for the electric light.

HARROW.—Some time back the Electric Lighting Provisional Order obtained by the District Council was transferred to Messrs. Crompton and Hawtayne, who have now notified the Council that they have named the Harrow Electric Light and Power Company (Limited) as their nominees, under the agreement between the old Local Board and themselves. Opposition to the transfer was shown at the last meeting, when it was proposed that the Council should notify Messrs. Crompton and Hawtayne that they were not prepared to go on with the contract. Only two members supported this proposal, and therefore the agreement will in due course be submitted to the Board of Trade for approval.

HENDON (MIDDLESEX).—The District Council are considering the advisability of applying for a Provisional Order for lighting the district by electricity. The Council have under consideration a proposal for lighting the district electrically by the Parfitt system.

ILFRACOMBE.—At a special meeting of the District Council last week called to discuss the electric lighting question, a motion that any further consideration of the matter should be deferred until September next, was approved on the grounds that it would be necessary to obtain expert opinion regarding the proposed purchase of the gasworks, and that, therefore, the electric lighting question should be shelved, at least for the present.

ISLINGTON (LONDON, N.).—At the last meeting of the Vestry a report from the Finance Committee, as to the properties acquired in Burnand-place for future extension of the electric generating station for £5,150, was presented. The Committee recommend that application be made to the London County Council to sanction a loan for this amount for 55 years. The report was agreed to.

KEYNSHAM.—Tenders for the extension of the public lighting in this district were discussed at the last meeting of the Parish Council, when the offer of the Western Electric Power and Light Company to light 77 lamps for £137 per annum, and to supply extra lamps at £2. 5s. each, was accepted.

LUTON.—A junction telephone line between Luton and St. Albans, where trunk line communication with London is now complete, has been erected by the National Company. The Luton town rate of subscription has been fixed at £10. 10s. per annum.

MANSION LIGHTING.—The contract for the electric lighting of Sir Richard Quain's London house has been entrusted to Messrs. Drake and Gorham. About 120 lights will be fixed.

MARYLEBONE (LONDON, W.).—The Vestry have appointed a committee to consider and report on the question of lighting the parish electrically.

MARGATE.—Messrs. Harrap, Hewitt and Duffield, of Queen-street, London, E.C., have been instructed to prepare a preliminary report on the proposed electric lighting of the borough by the Margate Town Council. They are further to advise on the Provisional Order which is to be promoted by the Council in the next Session of Parliament. The fee for these services has been fixed at 25 guineas.

MUSIC HALL LIGHTING.—The Star Music Hall, Dublin, which is said to be one of the largest music halls outside London, is to be lighted electrically.

OSSETT.—No considerable enthusiasm was manifested by the Town Council in a motion discussed last week to purchase the local gasworks. Several speakers pointed to the fact that the establishment of electric lighting works, either by the Council or by a local company, would have the effect of seriously depreciating the value of the gasworks property, and might ultimately leave them with £80,000 worth of gas works on their hands and by the casting vote of the Mayor a proposal to prepare a Bill authorising the Ossett and Aubrey gasworks undertaking, and also to establish an electric lighting works, was approved.

PANAMA.—Advices from Paris state that amongst the many difficulties experienced by the new company which is endeavouring to complete this unfortunate enterprise is the collapse of the Electric Lighting Company, and the imminent failure of the Electric Tramroad Company. About 900 men are employed on the Panama Works.

PORTSMOUTH.—The Town Council have obtained the formal sanction of the Local Government Board to the borrowing of £21,000 for electric lighting extensions.

PROVISIONAL ORDERS.—The Barmouth Electricity Supply Company have notified the District Council of their intention to apply for a Provisional Order to light the district electrically.——The Capital and Counties Electricity Supply Company have given the Wandsworth Board of Works (London, S.W.) notice of their intention to apply for a Provisional Order to supply electric current in the district.——The Brush Provincial Company have notified the Broadstairs and St. Peter's District Council (Kent) of their intention to apply for a Provisional Order for supplying electric current within the district.——At the last meeting of the Ryde (Isle of Wight) Town Council a notification was recevied from the Great Western Electric Light and Power Company that they intend to apply for a Provisional Order to supply electricity to the district. The Council decided to oppose the application.——The Guildford Electricity Supply Company have notified the Dorking District Council of their intention to apply for a Provisional Order to supply the district with electric current. It has been decided to oppose the application.——The Capital and Counties Electricity Supply Company have notified the Clerkenwell Vestry (London, E.C.) of their intention to apply for a Provisional Order to supply the district with electric current.——The Capital and Counties Electricity Supply Company have notified the Poplar District Board of Works of their intention to apply for a Provisional Order to supply electric current to the district.——The Capital and Counties Electric Supply Company have given the Surbiton District Council notice that they intend to apply for a Provisional Order to supply

Digitized by Google

electric current within the district. The Clerk was directed to inform the Company that the Council intended to carry out the electric lighting of the district themselves, under the Order which they have already obtained, and it was agreed that at least six firms be invited to send in plans and specifications for an electric lighting scheme.

RICHMOND (SURREY).—The Town Council have decided to sanction some further extensions of the electric light company's mains.

STAFFORD.—The Electric Lighting Committee's report to the Town Council recommends some further extensions of the mains, and the recommendations have received the approval of the Council.

TELEGRAPH WIRE EXPORTS.—Although the export trade of this country in telegraph wire and apparatus connected therewith was slightly more active last month than in May, the aggregate is far below that of last year. Exports increased from £26,942 in May to £99,572 in June, as compared with £341,646 in June last year. The returns for the first half of the year show that exports have amounted to £226,260, compared with £883,741 in the corresponding period of 1894, and £479,195 in the first half of 1893.

THEATRE LIGHTING.—The New Empire Theatre of Varieties, Blackpool, is lighted throughout by electricity. A system of electric heating for the dressing rooms has also been adopted. The work has been carried out by Messrs. Lowcock, Hill and Co.

THE BERNE VOCABULARY.—The members of the important New York Coffee Exchange have recently met and effectively pulled to pieces the new Berne Vocabulary. The citizens of New York are never anything unless they are thorough, and they bring no less than five important objections against the compulsory use of the new vocabulary. They have forwarded these objections to the managers of the international cable companies in New York, with a request that the objections may be laid before the International Telegraph Congress, which meets next year at Buda-Pest.

THE EUROPEAN GAS COMPANY AND THE ELECTRIC LIGHT.—The annual general meeting of the European Gas Company was held on Monday, Mr. J. Blacket Gill in the chair. In their report the Directors stated that one of the causes of the decrease in the rental was that the Company had now, with one exception, to contend with the electric light at all its stations. "The Directors have in many cases been able to meet this competition by introducing incandescent gas burners, and by making special concessions in price to large consumers, but in spite of these measures they have to acknowledge that their efforts are not entirely successful, and that where the cost of lighting is not a consideration they frequently lose good customers." The Chairman, in subsequently addressing the shareholders, stated that the general manager and he had visited their works this year, and had found everything in a satisfactory condition as far as the works were concerned. They could not, however, help being struck with the great inroads electricity had already made among their consumers, because there were rarely shops of any standing at all that had not the electric light. The café proprietors informed them that their customers almost insisted on having the electric light, not matter at what cost. The Company had therefore found it very difficult to compete with it.

WINDSOR.—A question as to how far the subject of producing electric current by water power for the use of this town was considered at the last meeting of the District Council. Mr. Alderman Dewe said the matter was in the hands of Mr. F. H. Medhurst, and the Electric Light Committee were awaiting his report. Particulars which had been required by Mr. Medhurst had been supplied by the Committee, and Mr. Medhurst is in his report to deal not only with the question of the best means of supplying the electric light, but also the addition of a refuse destructor. Some dissatisfaction was expressed at the delay in the settlement of the electric lighting matter, particularly as the Council possess an Electric Lighting Order.

WITHINGTON.—The Manchester Suburban Electric Supply Company have given the Withington District Council notice of their intention to apply for a Provisional Order to supply electric current within the district. After considerable discussion it was resolved at the last meeting that the Council withhold their consent to the proposal for the present, and a motion "that a sub committee be appointed to consider and report as to the desirability of obtaining powers to light by electricity the more populous portions of the district, and that they be empowered to retain the services of an electrical engineer for the purpose," was rejected by eight to four. The matter is to be further considered later.

WOLVERHAMPTON.—The Town Council have adopted the recommendation of the Lighting Committee (referred to in our issue of the 5th inst.) as to electric lighting extensions, at a cost of £5,000.

ANNUAL OUTING.—The employés of the Electrical Company of Charing Cross-road, and of the British Agency of the Calmon Asbestos and Rubber Works, of the same address, with a number of guests, held their second annual outing on Tuesday. A dinner was served on an electric launch, under the presidency of Mr. F. T. Eggers, the Managing Director. The numerous party enjoyed a pleasant holiday.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification a companies application an asterisk is suffixed.*

June 29, 1895.

12,596. A. G. NEW and A. J. MAYNE. London. Improvements in apparatus for automatically governing electric transformers.

12,613. J. G. LORRAIN. London. Improvements in or connected with electric railways or electric transport. (F. C. Esmond, United States.)

COMPANIES' MEETINGS AND REPORTS.

Eastern Telegraph Company (Limited).

The following report is issued by the Directors of this Company for the half-year ended March 31st last, and will be presented to the forty-sixth half-yearly ordinary general meeting to be held at Winchester House, 50, Old Broad-street, E.C., on Thursday next, the 25th inst., at one o'clock:—

The revenue for the period amounted to £420,526, from which are deducted £98,060. 4s. 8d. for the ordinary expenses and £52,730. 0s. 2d. for expenditure relating to repairs and renewals of cables, &c., during the half-year. After providing £3,222. 19s. for depreciation of spare cable, £1,813. 5s. due to revaluation of currency assets, and £5,812. 4s. 7d. for income tax, there remains a balance of £258,887. 6s. 7d., to which is added £59,175. 16s. 6d. brought from the preceding half-year, making a total available balance of £318,063. 3s. 1d. From this balance there have been paid—

	£	s.	d.
Interest on Debentures and Debenture stock	27,514	12	8
Dividend on Preference shares	20,296	6	8
An interim dividend of 2s. 6d. per share on the Ordinary shares	50,000	0	0
	£97,810	19	4

Leaving a balance of £220,252. 3s. 9d., out of which the Directors have placed £9,000 to the reserve fund for maintenance ships and £100,000 to the general reserve fund.

The Directors now recommend the declaration of a final dividend for the year ended March 31st of 2s. 6d. per share and a bonus of 3s. per share, amounting together to £110,000, both payable on the 25th instant, free of income tax, and making, with the three previous payments on account, a total distribution of 13s. per share or 6½ per cent. for the year on the Ordinary shares. The balance of £1,252. 3s. 9d. is proposed to be carried forward to the next half-year. The revenue includes £32,914. 10s. dividends and bonus for the half-year upon the Company's investments in the Eastern and South African, the Black Sea, the Direct Spanish, and the African Direct Telegraph Companies.

Anglo-American Telegraph Company (Limited).

The report of the Directors of this Company, to be presented at the ordinary general half-yearly meeting to be held at Winchester House, Old Broad-street, E.C., on Friday next, at 2 o'clock, is as follows:—

The total receipts from January 1st to June 30th last, including balance of £485. 6s. 2d. brought forward, amounted to £141,715. 4s. 11d., which is subject to revision, as the financial result of the judgment given in favour of this Company against the Paris and New York Telegraph Company cannot yet be determined. The traffic receipts show an increase of £9,382, compared with the corresponding period of last year. The total expenses of the half-year, including the repair of cables, &c., were £55,384. 2s. 4d., a decrease of £332. 13s. 2d. The Directors have, before declaring the net profits, set apart the sum of £12,000 to the renewal fund, leaving a balance of £74,331. 2s. 7d. One quarterly interim dividend of 10s. per cent. on the Ordinary stock, and of £1 per cent. on the Preferred stock, was paid on May 1st last, absorbing £35,000, and a second quarterly dividend of 11s. per cent. on the Ordinary stock, and £1. 2s. per cent. on the Preferred stock, amounting to £38,500, will be paid on August 1st, leaving a balance of £831. 2s. 7d. to be carried forward.

The Company's repairing s.s. "Minia" has been employed during the past half-year in the repair of the 1874 cable, broken off the coast of Ireland, and of two of the cables connecting Newfoundland with Cape Breton. She has also been employed by the Direct United States Cable Company for the repair of a cable belonging to that Company, the payment for which appears in the revenue statement.

West African Telegraph Company (Limited).

The following report of the Directors of this Company for the year ended December 31st last will be presented to the general meeting to be held at Winchester House, Old Broad-street, London, E.C., on Thursday next, at 2:30 o'clock:—

The revenue for the twelve months amounted to £64,761. 5s., against which £17,286. 18s. 6d. is charged for ordinary expenses and £13,473. 9s. 2d. for expenditure relating to repairs of cables, &c. After providing £916. 5s. 3d. for income tax and £26. 11s. 3d. due to re-valuation of currency assets, there remains a balance of £33,058. 0s. 10d. From this balance there have been deducted £11,900. 5s. 10d. for interest on debentures, and £11,766. 13. 4d. for sinking fund, leaving £9,391. 1s. 8d., which has been carried to the general reserve fund.

The Directors record, with regret, the decease of their colleague, Mr. Thomas Fuller, and notify that the vacancy on the Board has been filled by the election of the Hon. A. G. Brodrick. The Directors who retire by rotation are Mr. Robert Kaye Gray and the Hon. A. G. Brodrick, who offer themselves for re-election, as do the auditors, Messrs. Deloitte, Dever, Griffiths and Co.

Accompanying the report, a circular announces that the sum of £9,391 net revenue on the year's working, which has been placed to the credit of the reserve fund, is simply replacing the amount taken from this fund last year on account of heavy repairs. With respect to the year 1895, the result of the first six months' working justifies the Directors in paying an interim dividend of 2s. per share, which is at the rate of 2 per cent. per annum, and will be payable on the 26th instant.

National Telephone Company (Limited).

The report of the Directors of this Company for the half-year ended June 30th last, to be presented to the shareholders at the meeting to be held at the Cannon-street Hotel, London, E.C., on Friday, the 26th instant, at 1 o'clock, states that the income accrued in respect of the business of the half-year amounts to £393,855. 5s. 8d., compared with £359,891 12s. 6d. for the corresponding period of 1894, an increase of £33,963 13s. 2d. The working expenses for the half-year amount to £206,888 10s. 6d., compared with £187,089. 4s. 4d. for 1894, an increase of £19,799 6s. 2d. The net result (after deducting Post Office Royalties amounting to £35,263. 14s. 10d.) is a profit balance of £151,703. 0s. 4d., compared with £140,533. 11s. 2d. for 1894, or an increase of £11,169. 9s. 2d. The rentals carried forward for unexpired terms of running contracts amount to £390,978 3s. 4d., against £345,358. 18s. 5d. at the corresponding period of 1894, an increase of £45,619. 4s. 11d. Out of an available balance of £122,767 13s. 7d. the Board recommend the payment of a dividend at the rate of 6 per cent. per annum, less income tax, on the First and Second Preference shares, 5 per cent. per annum, less income tax, on the Third Preference shares, and 5 per cent. per annum, free of income tax, on the Ordinary shares; and also to transfer £35,000 to the reserve fund, carrying forward the balance of £3,288. 16s. 1d.

The draft of the formal agreement with the Post Office for the acquisition of the Company's trunk lines, having been laid upon the table of the House of Commons in accordance with the promise of the Postmaster-General, the preliminary agreement requisite to give effect to the arrangements was executed on March 15th last. The difficult and somewhat complicated details connected with the transfer of the Company's trunk lines are approaching completion, and payment of the purchase money, now in process of being ascertained, may be expected shortly.

A Parliamentary Committee on telephone questions has had during the past Session many sittings and taken much evidence, but has not made a final report. The inquiry stands over till the new Parliament assembles, when it may be hoped the questions submitted to the Committee will be speedily determined.

The Board, to their great regret, have to announce the resignation of his seat by Lord Balfour of Burleigh, who has taken office as a Cabinet Minister in the recently-formed Administration. During the period Lord Balfour of Burleigh has been a Director, his experience, counsel, and constant devotion to the interests of the Company have been invaluable. His withdrawal is a serious loss to the shareholders, and especially so to his colleagues, who will always retain the highest opinion of his ability, and the warmest feeling of personal regard towards himself. At the general meeting four Directors retire, viz., Mr. James Staats Forbes, Mr. Eli Heyworth, Mr. Samuel Herrick Sands and Col. Robert Raynsford Jackson. The three first named offer themselves for re-election, but Col. Jackson, owing to ill health, is compelled to sever his official connection with the Company, in the foundation and growth of which he has been so long and closely concerned. The auditors (Messrs. Welton, Jones and Co.) also seek re-election.

Chili Telephone Company (Limited).

The report of the Directors of this Company to March 31st last, which is to be submitted to the general meeting at Winchester House, London, E.C., on Tuesday, the 30th inst., at noon, states that a small addition to the tariff made in October caused some subscribers to withdraw, but others have been connected, making the aggregate number at all centres 4,015 at the end of the year, as compared with 3,987 at the beginning, or a gain of 28 for the year. The gross revenue from all sources for the past year compares favourably with that of the previous one: in 1894-5 it was $555,551, and in 1893-4 $504,188, an increase of $51,363. Owing to the additional expense incurred by reconstructing some of the trunk lines which were in bad condition, the expenditure in Chili shows an increase of $39,941.

The net income in Chili from all sources was: in 1894-5 $191,074, and in 1893-4 $179,652, or an increase of $11 422. The average rate of exchange was 13·61d., compared with 13·96d., a fall of 0·35d. Converted into sterling at these rates, the income was: in 1894-5 £10,835, and in 1893-4 £10,448, an increase of £387.

The liquid assets and liabilities in Chili on March 31st last were valued at 16⅞d., the current rate of exchange on that day, compared with 13d. on the corresponding date of the previous year. This increase represents £2,751, which has been carried to the reserve fund, raising it to £11,852. London expenditure is £116 less than in the previous year.

The net profit for the year of the whole business was £6,013, against £3,528 in 1894, and the Directors recommend the payment of a dividend of 2s. 6d. per share, being at the rate of 2½ per cent. per annum, free of income tax, leaving £513. 6s. 11d. to be carried forward.

Capital outlay during the year in sterling was £3,845, and the total mileage was:

	Miles.	Yards.
On March 31, 1895	6,420	80
„ „ 1894	6,169	432
An increase of	250	1,408

The General Manager in Chili reports that the prospects of the Company are encouraging, and that affairs are improving in every direction.

Owing to the death of Mr. Thomas Greenwood, Mr. George Keith has joined the Board and has been elected its Chairman. Mr. F. W. Jones offers himself for re-election as a Director, as does the auditor, Mr. Thomas A. Welton.

NEW COMPANIES, STATUTORY RETURNS, &c.

"BEST" MINERS' SAFETY LAMP COMPANY (LIMITED).—This Company was registered on July 11th, with a capital of £25,000, in shares of £10 each, to enter into an agreement made between W. Ackroyd, of Birkenshaw, and W. Best, mechanical engineer, of Morley (trading as Ackroyd and Best), W. M. Rennie, J. Graham and Harry Chapman, electrical engineers, of Morley, near Leeds (trading as Graham, Chapman and Co.), to purchase and generally deal with certain patents, and to carry on the business of manufacturers of and dealers in lamps of every description. The subscribers, with one share each, are: W. Ackroyd, A. Ackroyd, G. L. Pitt, W. Best, J. Graham, H. Chapman, and J. C. Best. Registered office: 48, Albion-street, Leeds.

GALLOWAYS (LIMITED).—This Company was registered on July 12th, with a capital of £115,000, in £100 shares, to take over as a going concern the business carried on by a company of the same name, incorporated in April, 1889, at Ardwick, Manchester, to enter into an agreement between the old Company and J. W. Pollitt (its liquidator) and the new Company, and to carry on the business of engineers, boiler makers, founders, tool makers, metal workers, electricians, suppliers of electricity for the purposes of light, heat and motive power, &c. The subscribers, with one share each, are: C. J. Galloway, E. N. Galloway, A. W. Galloway, J. H. Beckwith, H. Bowman, W. E. Norbury, R. Mottram and C. Rought. The first Directors are: J. Galloway, W. E. Norbury, C. Rought, C. J. Galloway, E. N. Galloway, A. W. Galloway and J. H. Beckwith—the four last-named to be Managing Directors.

CANTERBURY ELECTRICITY SUPPLY COMPANY (LIMITED).—The statutory return to October 30, 1894, was recently filed. Out of a nominal capital of £50,000, in £5 shares, only the seven subscribers' shares have been taken up, and no calls have as yet been made.

CHATHAM, ROCHESTER AND DISTRICT ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return to June 12th has been filed. The nominal capital is £50,000, in £5 shares. 3,890 shares have been taken up, of which 1,863 have been issued as fully paid. The full amount has been called on 2,000, and £2 per share have been paid on the remaining 27 shares.

CHINA AND JAPAN TELEPHONE COMPANY (LIMITED).—The annual return to May 28th has been filed. The capital is £20,000, in £1 shares, of which 14,761 have been taken up, and all issued as fully paid.

CUTTRISS, WALLIS AND CO. (LIMITED).—The annual return to May 10th has been filed. The nominal capital is £10,000, in £5 shares; of these 651 have been taken up, and 300 have been issued as fully paid. The full amount has been called on the remaining 351 shares; 120 shares have been cancelled.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The annual return to May 15th has been filed. Out of a capital of £3,000,000, in shares of £10 each, 250,000 have been taken up. The full amount has been called and paid on each of these shares.

ELECTRIC WIRE AND FITTINGS COMPANY (LIMITED).—The annual return to January 24th last was filed on June 27th. The nominal capital is £5,000, in £1 shares, of which 1,382 have been subscribed for and allotted, and the full amount has been called and paid thereon.

EVERED AND CO. (LIMITED).—The annual return has been filed. Out of a nominal capital of £200,000, in £10 shares, 16,496 have been allotted. The full amount has been called on 6,744, and £7 per share on the remaining 9,752.

GENERAL ELECTRIC TRAMWAYS COMPANY (LIMITED).—The statutory return to July 4th has been filed. The nominal capital is £50,000, in £1 shares, of which 5,007 have been allotted. The full amount has been called and paid. Of these shares, 5,000 are held by The Electric Construction Company (Limited).

NORWICH ELECTRICITY COMPANY (LIMITED).—The annual return to May 8th has been filed. The nominal capital is £50,000, in £10 shares, of which 2,695 have been taken up. The full amount per share has been called and paid.

CITY NOTES.

AMAZON TELEGRAPH COMPANY (LIMITED).—Letters of allotment in the recent issue of this Company's capital have been posted.

ANGLO-AMERICAN TELEGRAPH COMPANY (LIMITED).—The Directors of this Company, after placing the sum of £6,000 to the credit of the renewal fund, have declared an interim dividend for the quarter ended June 30th of 11s. per cent. on the Ordinary stock, and £1. 2s. per cent. on the Preferred stock, less income tax, payable on August 1st.

CITY AND SOUTH LONDON RAILWAY (LIMITED).—The accounts of this Company for the half-year ended June 30th show a balance, after providing for debenture interest and the full dividend on the Five per Cent. Preference shares, sufficient to allow the payment of a dividend on the consolidated Ordinary stock at the rate of 1½ per cent., carrying forward a balance of £965 to the new account. The dividend for the corresponding period last year was 1 per cent., the balance carried forward being £1,336. The traffic returns for the week ended July 14th were £848, as against £882 in the corresponding period of 1894, a decrease of £34. The total receipts for the half-year, 1895, amount to £1,763, against £1,761 in the corresponding period of 1894, an increase of £2.

DIRECT UNITED STATES CABLE COMPANY (LIMITED).—The Directors of this Company have resolved to recommend a final dividend of 2s. per share, free of income tax. With the interim dividends already paid this represents a distribution of 2 per cent. for the year. £7,000 is placed to the reserve fund account, and £1,410. 0s. 9d. is carried forward.

EDISON ELECTRIC ILLUMINATING COMPANY OF BROOKLYN.—At a recent special stockholders' meeting of this Company the capital stock was increased $750,000, to $3,750,000. The Directors were authorised to issue additional bonds to the amount of $500,000 for the purpose of purchasing the capital stock of the Citizens' Electric Illuminating Company and for extensions of the combined plants.

ELECTRIC ORGAN COMPANY (LIMITED).—Letters of allotment in the recent issue of the capital of this Company have, it is stated, been posted.

INTERNATIONALE ELEKTRICITATS-GESELLSCHAFT (VIENNA).—At the recent annual general meeting of this Company it was reported that during the past year there were applications for current equivalent to 28,000 16-c.p. lamps, which brings the total up to 110,000 lamps. In the same period the number of arc lamps rose from 1,059 to 1,536. The total capacity of the station is at present 5,400 H.P., but extensions are already in progress which will increase this output to 7,200 H.P. The Company has declared a dividend at the rate of 7 per cent. for the past year, against 6 per cent. in 1893.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 14th inst. amounted to £1,186. The amount for the corresponding week last year was £905; increase, £281.

LYNN AND BOSTON RAILROAD COMPANY.—This is a street railway company, incorporated in 1859, in the State of Massachusetts, U.S.A., and applications have been invited for $2,500,000 Five per Cent. First Mortgage Thirty-year Gold Bonds of $1,000 each, payable to bearer. The price of issue is 108 per cent., equal to £216 per bond. The issue is made through the Bank of Montreal. The bonds are secured by an indenture of mortgage, in virtue of which the total issue of 5,379,000 bonds (of which the present issue forms a part) are a first lien on the Company's property. The Company's system comprises 150 miles of track, all but seven of which are operated by electricity, the number of passengers carried in 1894 being 22,548,576. Since 1880 8 per cent. per annum has been paid on the capital stock of the Company, whose present capital amounts to $1,000,000, fully paid. The gross earnings of the Company have steadily increased from 1885 to 1894 from $368,670 to $1,238,410, with surplus profits of $36,210 and $113,078 respectively. Recent improvements and additions have resulted in an immense saving in the cost of producing power. The list for subscription opens on Monday next, and closes not later than four p.m. on the same day. The London address of the Bank of Montreal is 22, Abchurch-lane, E.C., and prospectuses can also be obtained from Messrs. J. and A. Scrimgeour, 18, Old Broad-street, London, E.C.

SMOKE AND FUMES ANNIHILATOR COMPANY, LIMITED (in liquidation).—A meeting of the shareholders in this failure was held on Monday last, when the liquidator, Mr. J. Satchell Hopkins, was authorised to deduct and retain 4s. per share to meet the expenses of liquidation, and the balance paid by subscribers to the Company's capital is to be returned to them. This was the scheme by which Mr. Samuel Elliott, of Newbury, proposed to consume smoke from all descriptions of chimneys, but which has itself ended in smoke, causing serious loss to the shareholders in the Company and bankruptcy to Mr. Elliott himself.

ST. JAMES'S AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend at the rate of 7 per cent. per annum on the Preference, and 4 per cent. per annum on the Ordinary, shares for the past half-year. The sale of electric current for the quarter ended June 24th last, at 6d. per unit, amounted to £8,593, as against £7,380 at the same rate for the corresponding period of 1894.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have ordered the following securities to be quoted in the Official List:—Further issue of £200,000 Five per Cent. Debenture Stock of the City of London Electric Lighting Company (Limited), in lieu of the provisional certificates now quoted; and 15,000 Preference shares (Nos. 1 to 15,000) of the Tramways Electrical Traction Company (Limited), in lieu of the shares of the Tramways Company of France (Limited) now quoted.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).—As announced in our last issue, an interim dividend of 12s. per share will be paid by this Company, and the transfer books will be closed from the 15th to the 23rd inst. inclusive.

WATERLOO AND CITY RAILWAY COMPANY.—The third half-yearly general meeting of the shareholders of this Company takes place at Waterloo Station, London, S.E., on August 8th, at 2:30 o'clock. The transfer books will be closed from July 25th to August 8th inclusive.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended July 12th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,356.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the fortnight ended the 15th inst. were £1,658, as compared with £2,009 for the corresponding period of last year. The March receipts estimated at £5,902 realised £5,891.

YORKSHIRE HOUSE-TO-HOUSE ELECTRICITY COMPANY (LIMITED).—To provide funds for the extension of this Company's electricity works subscriptions are invited from the present shareholders of the Company for 9,900 Ordinary shares of £5 each. The prospectus states that the extension of the works is necessitated by the increasing demand for electric current in the city of Leeds. It is proposed to erect a new engine and boiler house on the remaining land which the Company has, and to instal plant equal to 1,000 I.H.P. Should any of the shares now issued remain unapplied for, the Directors take power to dispose of them as they determine.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 897. [No. 13. Vol. XXXV.] FRIDAY, JULY 26, 1895. PRICE SIXPENCE.

NOTES.

OUR readers, we feel sure, will share our own pleasure in the resumption this week of Mrs. AYRTON's instructive series of articles on "The Electric Arc." The four months that have elapsed since the publication of the last batch of Mrs. AYRTON's experimental results have been devoted to an exceedingly laborious investigation, and the net result is an equation which represents with surpassing accuracy the connection between volts, amperes and length of arc. The time and labour required to attain this end may be gauged by the fact that with small currents the carbons require from one to two hours to properly form, and that no reliable potential difference reading can be taken before this. Again, almost every point in Fig. 33 represents the mean of several results obtained at different times with different pairs of carbons. In her next article Mrs. AYRTON proposes to discuss previously published equations; these, whilst having an attractively simple appearance, and possessed of apparent generality, scarcely fit the facts so well as the equation deduced by Mrs. AYRTON, and were not, we venture to say, so firmly based on solid experimental work.

WE publish in this number an article by Dr. BEHN-ESCHENBURG, which comes at an opportune moment. At a recent meeting of the Physical Society, in the course of the discussion of a communication from Mr. W. G. RHODES on the running of synchronous alternator motors, Prof. SILVANUS THOMPSON remarked that before the question of stable running could be decided the whole question of the armature reaction in alternators needed investigation. Dr. BEHN-ESCHENBURG's article is a contribution to the subject. His method may be briefly described thus: Having first determined the characteristic curve on open circuit, he determines also for the same range of field excitation what is the electromotive force, and the phase of the same, required to drive the current through the alternator armature itself. From this he determines by use of vector diagrams the magnitudes and phases of the components, depending on the coefficient of self-induction, the armature resistance and the demagnetising action of the armature coils, and eddy currents. Having once determined these components, then for any field excitation and load, and any phase difference between the electromotive force at the terminals and the current, he determines by other vector diagrams the relation between the full electromotive force of the armature and the potential difference at the terminals. Unfortunately, the method is an analytical one only, and difficult to use in designing because some of the important elements have to be determined experimentally; but as indicating the method of attacking the problem the article is very suggestive.

WE cannot, however, agree with Dr. BEHN-ESCHENBURG's contention, that the factor which determines the efficiency and "quality" of an alternator is the fall of potential from open circuit to full load, because this must depend on the purpose for which the machine is designed. Some alternators, principally by American manufacturers, are specially designed, so that on short-circuit the current will not much exceed the full-load current. Specifications have been issued in England recently requiring the current on short-circuit not to exceed by 100 per cent. the normal full-load current. Such alternators could hardly be used if the work to be done was largely motor work, but beyond requiring additional regulation there is little objection to their use for lighting. But, besides this, it is possible to design an alternator so that the phase of the current always leads on the phase of the electromotive force at the terminals, and thus the armature reaction raises the electromotive force. The efficiency and "quality" of such a dynamo would exceed 100 per cent. were Dr. ESCHENBURG's view a correct one.

IN another column will be found a contribution to the controversy respecting the chemical reactions which take place in lead secondary batteries at present being carried on between M. DARRIEUS and various opponents. We could wish that Messrs. ELBS and SCHÖNHERR had followed up their experiments on the electrolytic formation of persulphuric acid by experiments on various cells in actual commercial use, as was done by Mr. ROBERTSON, who first suggested that an important part was played by the reactions occurring in the acid. The latter observer found hydrogen peroxide the principal oxidation product in cells containing acid of density 1·18, while persulphuric acid was the chief constituent in those containing acid of density 1·2, and though a large number of cells engaged on different work were examined, oxidised bodies were found in the acid in every case. Messrs. ELBS and SCHÖNHERR point out that with acid of density of 1·15, and a current density of 4,000 amperes per square metre, and using a platinum anode, no persulphuric acid at all was found. It would be interesting to know

Digitized by Google

whether, with the same current-density, and using a lead anode, any peroxide of lead would be formed, as Messrs. Gladstone and Tribe found that with low-current density lead sulphate was the sole product on the positive plate, while by diminishing the strength of the acid, keeping the current constant, the formation of lead peroxide nearly ceased, and a white substance, supposed to be a basic sulphate, took its place. It may well be that, though both persulphuric acid and peroxide of lead depend for their formation on the strength of the acid as well as on the current-density employed, there is no real relationship between them, and that they may be produced independently of each other; but the elucidation of this point would go far to clear up the doubts concerning the chemistry of the lead cell.

Just a year ago we referred in our leading columns to the risk run by modern science of being buried beneath its own accumulations, and to the proposal of the Royal Society to avert this danger by the compilation of an international catalogue of scientific Papers. In another column will be found an abstract of the Report of the International Catalogue Committee, from which it will be seen that the scheme, as was to be anticipated, has met with warm support, and that the net step is to be the calling together in July, 1896, of an International Conference to discuss and settle details. It is to be regretted that replies have only been received from some 50 per cent. of those to whom the Royal Society's circular-letter was sent. On the other, hand it is a matter for congratulation that in no single case was any doubt expressed as to the extreme value of the proposed undertaking, although, unfortunately, no precise information was forthcoming as to what the scheme might be expected to cost, where the money is to come from, and on what lines the idea is to be carried out. We note with satisfaction that English is the language most generally favoured. To our thinking the one factor essential to the success of this vast undertaking is that the actual labour of indexing shall be done by men who have actually read and *digested* the papers to be indexed, and that it shall not be relegated to mere index makers, however clever and conscientious. A central bureau will, of course, be required to collate and correct and publish; but to entrust the actual compilation of the catalogue to a body of individuals without any occupation in life other than this deadening one will result in failure. An index compiled by an army of human machines can serve no useful purpose. The outside co-operation of experts can alone ensure success.

The motion for an injunction against the County of London and Brush Provincial Electric Lighting Company which the Wandsworth District Board of Works brings to-day before Mr. Justice Stirling raises a somewhat important issue. From the beginning, the Wandsworth Board of Works has objected to the construction of transformer-pits under the pavements, and acting in conjunction with the London County Council endeavoured last year to persuade the Board of Trade to veto their use. The decision of the Board of Trade last December was, it will be remembered, in favour of properly constructed transformer-pits, the Board of Trade further holding that it had power under Clause 12 of the Electric Lighting Orders Confirmation (No. 5) Act, 1892, to authorise the transformer-pit system. The clause in question is indeed headed "Street Boxes," but as these may contain apparatus for the regulation and control of the supply of energy, it would appear that "street box" is an elastic term, and might without undue straining be stretched to include a transformer-pit. This is the point which Mr. Justice Stirling is called upon to settle.

After a lengthy and pertinent discussion the London County Council has decided to obtain further information with regard to the cost of the present system of lighting the Thames Embankment and bridges, and estimates of the cost of lighting by incandescent gas burners and by arc lamps supplied with current from a company's mains; the recommendation of the Highways Committee to erect a special municipal station for the sole purpose of this scheme not meeting with much support. Whatever may be the ultimate result of this set-back to the electric lighting of the Thames Embankment, the step taken by the Council is an unusually sensible one. For our own part, we do not fear an impartial investigation by experts of the relative merits of arc and Welsbach lamps for the illumination of main thoroughfares; but it is quite right to make perfectly sure that no mistake is being made in spending nearly £17,000 of the ratepayers' money. Further, it is even more desirable to ascertain whether the work cannot be done equally well and somewhat cheaper by taking the current required from the mains. An annual charge of £2,768, or £33 per arc lamp per annum, is excessive, even if we make allowance for the fact that the capital outlay, which also appears unduly large, has to be repaid in 42 years. We are not at all sure that small arcs placed in the existing handsome gas standards on the Embankment parapet, and supplied with current by a company, would not be found to be on the whole the best and most economical plan.

University College, Bristol.—The session of the Chemical Department of this College begins on October 3rd next.

Journal of the Society of Arts.—The new Index to the *Journal of the Society of Arts*, for Vols. XXXI. to XL. (1882-1892), is now ready.

Académie des Sciences.—Prof. Ramsay has been elected Foreign Correspondent of the Chemical Section of the Académie des Sciences in place of Prof. Frankland.

The Welsbach Light.—The report of the Directors of the Incandescent Gas Light Company for the year ended March 31, 1895, states that the sales of burners for the years ended March 31, 1893, 1894, and 1895, have been approximately 20,000, 105,000, and 300,000 respectively.

Cable Interruptions.—There are again no cable interruptions to notify this week. It is a remarkable fact that the Eastern Telegraph Company have no less than three of their cable steamers laid up in dock in London at the present time.

Purchase of the Liverpool Electric Supply Company's Undertaking.—The purchase by the Corporation of the undertaking of the Liverpool Electric Supply Company has been effected. The sum to be paid amounts to something like £400,000. At the meeting of the Lighting Committee on Monday it was decided that the Chairman, Alderman F. Smith, should draw up a report detailing what had been done, for the information of the Committee and also of the public.

Polyphase Currents.—Next week Messrs. E. and F. N. Spon will publish a new work on polyphase electric currents and

Digitized by Google

alternate-current motors, by Prof. Silvanus Thompson. It runs to 250 pages, and has two plates and numerous cuts. At a moment when so much attention is being drawn in the engineering world to the uses of polyphase currents, at Niagara and elsewhere, the book is opportune. Those who are interested in such matters will be glad to know that Prof. Thompson does not omit to mention the two-phase generating station which was established in London so far back as 1883, and which has therefore been 12 years in successful operation.

Personal.—Mr. H. W. Ravenshaw, who has for the past eleven years been chief of the electrical staff of Messrs W. T. Goolden and Co., whose business is now merged with that of Messrs. Easton and Anderson, of Erith, has gone into partnership with Mr. Robert Booth, consulting engineer, of 110, Cannon-street, London, E.C. Mr. Ravenshaw's services have been retained by his old firm as consulting electrical engineer. We wish Mr. Ravenshaw every success in his new departure.

Deaths by Lightning.—On Friday last week at Pockleton, Leicestershire, a farmer in company of his son and nephew, took refuge from a thunderstorm under a hedge, when the lightning struck him and killed him on the spot. The two others escaped uninjured.—Dr. J. T. Reece, a medical practitioner at Ystradgynlais, Breconshire, when out riding on Friday last was killed by lightning, also his horse.—During a heavy thunderstorm on Tuesday last the Belle Vue Church, West Hartlepool, was struck by lightning, and the tower fell with a crash.

The Durability of "Asphalte" Cables.—Herr Görz, of St. Petersburg, writing in the *Elektrotechnische Zeitschrift* on the proposed German wiring rules, and proposing several amendments, refers to the question of the durability of insulated cables. He states that the whole underground network of the St. Petersburg Electric Supply Station consists of lead-covered "asphalte" Siemens-Halske cables, which have been working for the last six or seven years to entire satisfaction. The expenditure for repairs and renewals for the last year was only ½ per cent. of the total expenditure of 1,100,000 silver roubles on cables.

Artistic Designs for the Embankment Electric Lamps.—The following letter appeared in Wednesday's *Times*, over the initials "J. R. C.":—

SIR: Considerable interest attaches to the resolution of the Highways Committee on what, to some, may seem a small matter; I refer to its timely aim to employ artistic design for the electric lamps and standards to be adopted for the Victoria Embankment. On such ground it is devoutly to be hoped that the resolve in question may lead to commensurate results, "worthy," as the report puts it, "of the finest thoroughfare in London." The step is manifestly in the right direction, for it may spare us from further abominations in the character of our public gas lamps and standards, and promote the expression of artistic taste in such work. Nothing can be so art-promoting and potent in educational influence as the element of beauty in things of common public use. It is proposed to invoke the aid of the "art schools and classes" for the designs in question. I fear the said schools and classes have, as yet, made little or no impression in such directions. Better would it be to invite the wider scope of open competition by drawings, or, better still, models to small scale. Such invitations would, doubtless, induce artistic minds and hands, in this new departure, to deal a death-blow to the abortions which, in such form, have been hitherto inflicted on the metropolis. In Paris, how different! There the prominent contrast in every thoroughfare is seen in the common lamps and standards—admirable works of art, masterly in their elegant proportions, and beautiful in their refined detail. As an artist, my Continental studies have included sketches of the lamps and lamp-posts of Paris, in the art of which I have found fruitful study and extreme pleasure.

Iron Pipe Wiring.—We had the pleasure a few days ago of inspecting the wiring of the new premises of the Commercial Union Assurance Company in Cornhill, which, we believe, is the first large installation in London where the whole of the wiring has been carried out in iron pipes. The installation is in two parts, one for the main building and one for tenants. The total number of 16 c.p. lights will be about 800. The three-wire system is used throughout, alternate lights being in either circuit. On entering, after passing through main switches and fuses, the mains run to two chases built into the staircase well, running to the top of the building. The mains for the tenants are carried up one chase in an iron pipe, a cast-iron box being inserted at each floor, in which tappings are made for the services to different tenants, and in which the fuses for these services are placed. From these boxes service wires are run to a meter and distributing fuse-board fixed in the tenants' offices. The leads for the main building are carried direct up the other chase to the fifth floor, where a board is fixed from which leads run back to each floor, and on which switches and fuses controlling each floor separately are fixed. A distributing fuse-board is also fixed on each floor, from which three wire circuits branch out to the lights. All fuses, with the exception of those in the floor plugs, are grouped on these boards. The wires are everywhere run in wrought-iron pipes (coated with Argus Smith composition) buried in the floors and walls, specially designed cast-iron boxes being inserted wherever a sharp bend occurs. Similar boxes are inserted over all drop points, and all joints are made in them. The greater number of pipes are ¾in. and ½in., the main pipe up chase being 3½in. The wires are all Henley 2,000 megohm vulcanised rubber. The work has been carried out by Messrs. Hayward Tyler and Co. to the instructions of Messrs. Handcock and Dykes, who are so satisfied with the way in which the system works out, and so impressed with its advantages that they have introduced it also into the Guardian Fire Insurance Company's new premises and the Clydesdale Bank, Lombard-street, and also in certain provincial installations.

The International Catalogue of Scientific Papers.—The following is a brief abstract of the report of the International Catalogue Committee, presented to the President and Council of the Royal Society on July 5th. The recommendations were approved. The report will be found in full in *Nature* (July 18th). The first meeting of the Committee was held on February 8, 1894. A circular letter was prepared and issued; this letter was sent to 207 societies and institutions selected from the exchange list of the Royal Society, and to a few others. A special letter was addressed to the Smithsonian Institution. More than a hundred replies were received, several being reports of Committees specially appointed to consider the suggestions put forward. In no single case was any doubt expressed as to the extreme value of the work contemplated, and only two or three correspondents questioned whether it was possible to carry out such a work. The importance of having complete subject catalogues, and not mere transcripts of titles, was generally recognised. Some bodies and individuals took the matter up very warmly, and urged that steps should be taken forthwith to put the scheme into action, this being especially true of the replies received from the United States; others, while giving a general approval, dwelt upon the difficulties of carrying out the suggestions put forward; and others, again, asked for more details. Over and over again reference was made to the great value of the Royal Society's "Catalogue of Scientific Papers." There is abundant evidence that considerable use is made of this on the continent of Europe. And it is clear that a proposal to carry out a more comprehensive scheme initially under the direction of the Royal Society of London is likely to meet with general approval, owing to the fact that the Society is credited with having already carried out the most comprehensive work of the kind yet attempted. No very precise information as to the best mode of putting the scheme into operation was to be gathered from the replies as a whole. In no case was any attempt made to form any exact estimate of the cost. As regards language, over and over again the opinion was expressed that English should be the language of the subject catalogue. Some form of card catalogue appeared to be generally favoured, especially in America, as the basis of the scheme. From various sides it was urged that an International Congress should be held to discuss plans. Such being the tenour of the correspondence, the Committee stated they were convinced that initial steps of a definite nature in furtherance of the scheme ought to be taken. They accordingly requested the President and Council to take measures with the view of calling together, in July, 1896, an International Conference, at which representatives of the several nations engaged in scientific work should be invited to attend, with the view of discussing and settling a detailed scheme for the production by international co-operation of complete authors' and subject catalogues of scientific literature, a detailed scheme to be immediately prepared, to serve as a basis for discussion at the Conference.

GAS ENGINE ELECTRIC SUPPLY STATIONS.—II.*

Belfast.

The latest development in gas-engine stations for electric supply is represented by the station recently put into operation by the Corporation of Belfast. As long ago as February, 1893, the plans for a system of supply to a limited area were laid before the City Council by Prof. A. B. W. Kennedy, and were accepted; these forming the scheme upon which the present works have been carried out. No doubt, on account of the experimental nature of the trial of gas power, as well as from the fact that it is a simpler matter to duplicate such stations than stations driven by steam power, it was decided to restrict the capacity of the station to 8,500 lamps, allowing that only 6,100 lamps will be alight simultaneously in the ordinary course.

System Adopted.—The system which was decided upon by the Corporation, on the recommendation of Prof. Kennedy, was as follows. Power was to be derived from the Corporation town gas mains, the gaseous fuel being used to drive gas engines; these engines were to be geared by ropes to continuous-current dynamos, which, in conjunction with a large storage battery, were to feed a network of 220-volt three-wire mains, consisting partly of bare copper strip and partly of covered cables, by means of feeders of copper strip and covered cable. Balancing dynamos and a suitable system of battery switching were to be employed for keeping the two 110-volt sections of the three-wire system properly regulated. The scheme included no provision for street lighting; but, as has been said, it made ample allowance for the supply of 6,100 glow lamps simultaneously. The estimated cost of the plant for the generation, storage, and distribution of power for this system of supply was £19,000, exclusive of land, buildings, and consumers' meters. Contracts were arranged with the following firms:—

Gas engine plant	Dick, Kerr and Co.
Dynamos	Siemens Bros. and Co.
Electric storage plant	The E.P.S. Co.
Switchboard	J. H. Holmes and Co.
Bare copper strip	Curtis and Sons.
Covered cables	Callender Bitumen Co. and British Insulated Wire Co.
Road work	Scott and Sellar.
Buildings	M'Laughlin and Harvey.
Cast ironwork	R. Maclaren and Co.

We understand that the actual cost of carrying out the works was considerably below the estimated figure, and that the utmost capacity of the generating plant is somewhat in excess of its specified power.

Generating Station.—The site selected for the generating station lies on the border of the present area supplied with power, as will be readily seen in the accompanying map (Fig. 1). It consists of a narrow strip of land, formerly the site of a tannery, between Marquis-street and Chapel-lane. The extreme length of this strip of land is 185ft., and the width is shown in Fig. 2, which shows a plan and sectional elevation of the engine and battery buildings. The whole of the buildings were constructed to the designs of Mr. C. S. Peach, of London. The general arrangements of the engine and battery rooms, and of the outlying offices, &c., may be learned from Fig. 2, by means of the key which accompanies that illustration. In every way these seem well adapted to the peculiarities of the system and to give efficient service. Fig. 3 is from a photograph of the interior of the engine room, looking in the direction of the switchboard. At the far end may be seen the 6-ton traveller, by Messrs. Marshall, Fleming and Jack, which can be run over the entire length of the engine room. The interior of the room is lit at night by arc lamps suspended from the roof and by a number of glow lamps placed on brackets along the walls.

The present equipment of the engine-room comprises altogether six sets of rope-geared gas engines and dynamos. Four of these sets are for the general supply through the feeders, and the remaining two—which are of smaller power —may be used either for this same purpose or for balancing the three-wire sections. The smaller dynamos are provided with special commutator arrangements—which will be described presently—to enable them to fulfil this double duty, being in the former case required to give 220 volts, and in the latter instance only half that pressure. Gas is metered into the station through two large meters, and passes along one large supply pipe, from which branch pipes convey the gas to the several engines. The Corporation makes a charge for gas at the rate of 2s. 3d. per 1,000 cubic ft. The charge to townsfolk for gas is at the rate of 2s. 9d. per 1,000 cubic ft., with discounts. The exhaust gases are conveyed away from the engine through pipes which Tee into one common exhaust main, and this main pipe conveys the gases to a suitable but simple silencer, and thence to an up-take, from which the discharge takes place slightly above the level of the roof. The silencer consists of a small cylindrical chamber, provided with an inlet at the bottom and an outlet at the top, and with a number of perforated baffle plates, to intercept the passage of the gases. It is found that when several engines are working the impulses tend to damp out all or nearly all the sudden rush of gas, which is the cause of the noise nuisance; while when only one engine is running the passage through the pipes is so ample, in proportion to the volume of gas discharged, that there is no great rush of gas, and consequently no serious noise. At any rate, the employment of one common exhaust main, in place of independent exhaust pipes and "silencers" which are used at Morecambe and in other places, is a great advance, and a step towards surmounting the noise nuisance in gas-engine stations. No less adequate are the provisions which have been made for jacketing the engines at Belfast with cold water. Besides a large cooling tank, seen in Fig. 2, by means of which the circulation of water may, with ordinary loads on the station, be maintained sufficiently cool, there are arrangements for running town water straight through the water jackets to the drains, or for admixing town water with the tank water in any proportion which may be required to cope with the waste heat from the engines. Each engine is also provided with a circulating pump, for driving water through the jackets. The town water is metered into the station, and the charge made is at a rate depending on the consumption. For only 100,000 gallons per annum a charge of 10d. per 1,000 gallons is made, while for over 1,000,000 gallons per annum the rate is

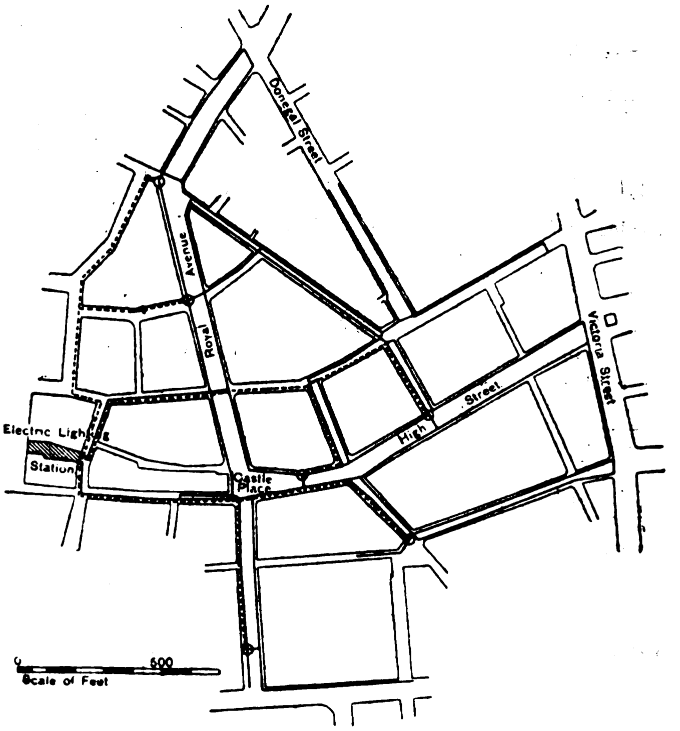

Fig. 1.—Map of Area of Supply, showing Feeders and Distributing Network, and Position of Generating Station.

Digitized by Google

only 5½d. per 1,000 gallons. Pausing for a moment to comment on this, we may observe that the price of jacket water may become a serious item in a gas engine station, and that in towns, where high prices are charged, it may be cheaper to expend capital on a spacious cooling tank than to take water—except for evaporation make-up—from the mains. Such a system of cooling would also be more advantageous in a small station than in a large one.

Gas Engines.—As already has been stated, there are six gas engines now installed. These have been constructed to Prof. Kennedy's specifications by Messrs. Dick, Kerr and Co., of Kilmarnock. Four of these engines are capable of developing a maximum of 120 I.H.P., and are used for driving four Siemens 60-kilowatt dynamos. The remaining two engines are coupled to Siemens 26·5-kilowatt dynamos. The contractors have guaranteed that the consumption of Belfast gas by these engines, when at their rated load, shall not exceed 26 cubic ft. per electrical horse-power per hour, as measured at the dynamo terminals. We understand that by a six-hours' trial at the contractors' works, it was found that the consumption of Kilmarnock gas did not exceed 24 cubic ft. per electrical horse-power hour, under the specified conditions. The combined $\frac{\text{E.H.P.}}{\text{I.H.P.}}$ efficiency of the engines proved to be about 76 per cent. In regard to the quality of Belfast gas, we may state that, although we are not in a position to publish any analysis of this fuel, there are circumstances which make it probable that its calorific value suffers appreciable change from time to time. This gas is not simple coal gas; but consists of coal gas which has been largely admixed with enriched water gas; *i.e.*, carbon monoxide and the vapour of highly volatile hydro-carbons. We understand that the proportion of this enriched monoxide which is used varies with the relative price of gas coal and enriching oil, as well as with the amount of coke in stock at the gas works. The effort of the gas authorities to maintain a fairly constant illuminating power will have no effect in keeping the calorific power of the gas constant. Incidentally, while referring to the existence of large amounts of carbon monoxide in the town gas of Belfast and other cities, we may remark that it must be much safer to the public for such gas to be burned in public stations than in private houses; also, that if it is considered safe enough for water gas to be led into private houses, there ought not to be any serious danger in using it—*à la* Dowson gas—in an electric supply station. We understand that, at present, there is no Board of Trade regulation in respect to the proportion of poisonous monoxide which may be admixed with coal gas for town supply, and that in some towns so much as 30 per cent. of water gas is used.

Messrs. Dick, Kerr and Co. had already acquired some considerable experience in the matter of designing gas engines for electric supply stations when they commenced to build the Belfast engines, for it was that firm who were the makers of the Coatbridge engines. At Coatbridge they had introduced the double-acting type of engine, and had provided for an impulse every stroke by placing two cylinders on the same engine. But at that place the cylinders of each of the two-cylinder engines were cross-coupled, or arranged side by side. This involved the use of two cranks, two connecting rods, &c., and an engine of more than double width. In the Belfast type of engine—speaking now only of the larger engines, for these alone have two cylinders—a very important and useful modification has been introduced; for, while these engines have each two cylinders, both double-acting—and are thus capable of giving an impulse at each stroke—the two pistons are arranged on the same rod, there is only one crank, the cylinders are placed in tandem, and the width of the engine is no more than that of a single-cylinder engine of half the power. In order that this arrangement might not spoil by increased length the economy of space which resulted from decreased breadth, the method of backward driving was

adopted, the cylinders being located between the flywheel and the dynamo alongside of the rope-drive. Thus the amount of floor space covered by the plant is actually less than would be required by a forward-driving single-cylinder engine of equal power. Again, in order that backward driving should not put the ropes into slack tension at the bottom and tight tension at the top—a plan which would cause the ropes to lift off the pulley grooves except over a small arc, thus making the ropes slip—it became necessary to design the engine so that it would turn the flywheel in the reverse to the usual direction. That this method results in getting a compact engine room, a glance at the photograph (Fig. 3) will suffice to show. A set of scale drawings of one of the larger of the Belfast engines is shown in Fig. 4. The drawing on the left of the plan represents a section transversely through the valve box.

The cycle of operations which is carried on at each end of both cylinders is the well-known Otto cycle. The phase relations of the four cycles are adjusted so that, at full load, there is a quick succession of impulses; no two impulses in any one engine occurring at the same time. The explosions occur in the following order: first, there is an explosion in the back end of the back cylinder, then one in the front end of the front cylinder, then one in the back end of the front cylinder, and, finally, one in the front end of the back cylinder. The advantages of this system, from an electrical point of view, are enormous. Not only is there a more rapid succession of impulses, but the magnitude of each impulse is correspondingly reduced. The quick succession of impulses enables a flywheel of moderate inertia to suffice to store the fluctuating energy; and the fact that each impulse is only one-quarter of that which would arise were the whole power merged in one impulse reduces the amount of fluctuating energy to be stored. Thus, by the distribution of the load among four suitably arranged Otto cycles, it is probable that the tendency to fluctuation is reduced to one-sixteenth of the tendency in a single-acting single-cylinder engine of equal horse-power and flywheel inertia.

The engines are designed to run at constant speed—160 revolutions per minute—at all loads, accurate speeding-up being as yet practically impossible in gas engines. At full load there will therefore be 320 impulses per minute. It is not intended, as is done at Morecambe, to run the engines at full load during the whole time of working; but provision has been made for economically meeting the conditions of a varying load. Of course, for economical reasons, the load will always be kept as full as can be; but, what we mean is, that the engines will not be run without a governor, necessarily at full load whenever they are running, as is done at Morecambe. It was originally intended to arrange that at reduced loads the engines would systematically miss one or more of their 4-cycle explosions. The following is a detailed account of what would take place in such an arrangement. As the load falls from its full or normal value, the valves automatically reduce the proportion of gas and air admitted for each explosion, and this reduction goes on until a certain reduction of load is reached, at which point an entire explosion is missed. This point corresponds to about three-quarters of the rated indicated horse-power, and when it is reached only three of the Otto cycles come into action. If the load falls still further a further reduction of the proportion of gas and air is effected by the valves; and at half load two of the Otto cycles will have been cut out, and only one explosion in each cylinder will be taking place. Below a quarter load there will be only one explosion out of the four, and as the load still more is reduced the force of this single explosion will be diminished by the reduction of the amount of gas admitted for each charge. This fine gradation of explosive power and of the frequency of the explosions would enable a high degree of regulation to be obtained; but the plan of missing explosions has, we learn, not been finally adopted at Belfast, it being found to be preferable to arrange that the whole of the regulation by the governor shall be effected by varying the proportion of gas used in all four explosions. There is no doubt that the practice of retaining the full number of explosions at reduced loads must enhance the conditions of steady driving at those loads. It may be mentioned that great care has been taken to ensure good lubrication of the cylinders; the cylinder oil is admitted from the top of the cylinders by the suction exerted when the charging stroke is being made by the piston. An inward-opening oil valve is opened by the suction, and allows a small quantity of oil to be carried into the cylinder. The four large gas engines are each provided with 8ft. 5in. cast-iron grooved pulleys, which drive the large dynamos by means of eight ⅞in. ropes on each pulley. In addition to the grooved pulley each crank shaft carries a heavy cast-iron flywheel for giving greater steadiness in running.

The two smaller gas engines are of the single-cylinder double-acting type, and provide an explosion at every revolution when working at full load. So far as the distribution of the gas and air is concerned, and the cycle of operations at each end of the cylinder, the smaller engines differ in no respect from the larger ones. Regulation for reduced load is

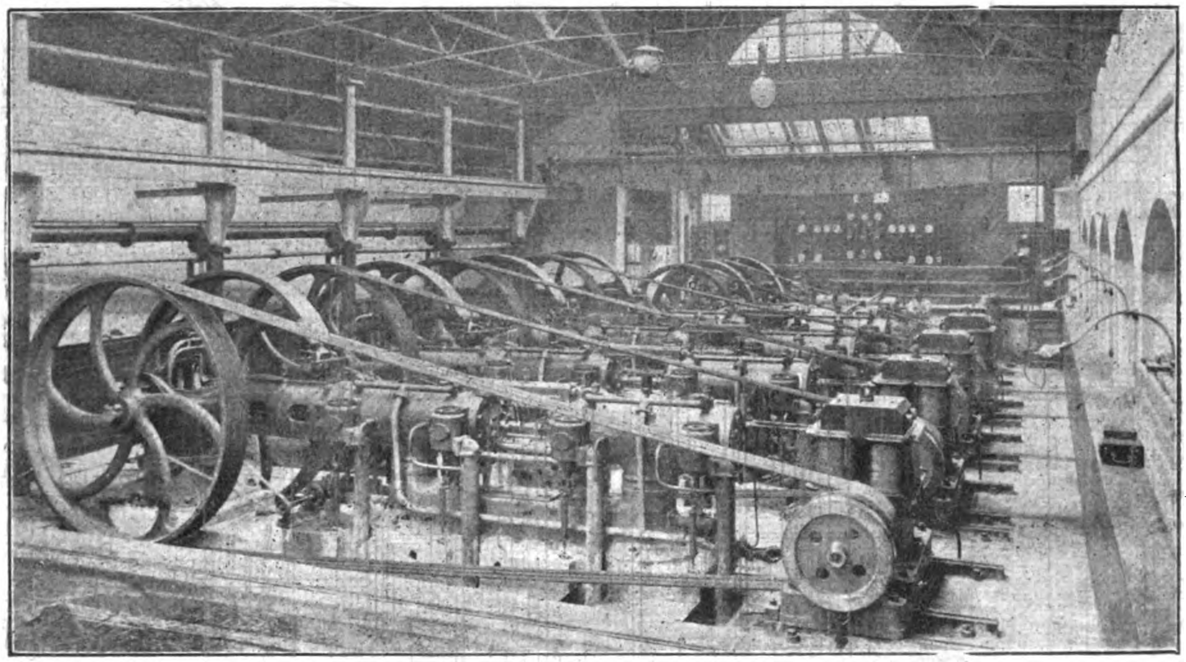

Fig. 3.—Engine and Dynamo Room, looking towards Switchboard.

Digitized by Google

also effected, first by a graded charge, and afterwards by cutting out explosions. Each of these engines has a grooved cast-iron pulley, 7ft. in diameter, carrying eight ¾in. ropes, and a smooth-faced cast-iron flywheel.

One of the problems in connection with a gas-engine station is: how to arrange to economically and quickly start the engines as they are required. The old-fashioned plan of assembling the staff and friends for the ceremony may do very well for small engines in private installations, but is out of the question with large-power engines. The plan adopted at Coatbridge of starting the engines by admitting high-pressure steam for a few forward strokes is permissible where there is a boiler for generating water gas, but is inadmissible where town gas is used. The practice of pumping or otherwise admitting an explosive mixture into the motionless and inert engine, and then firing the machinery into activity by one sudden blast is used in some places, but it puts a heavy strain on the parts which are thus suddenly set in rapid motion, and it is not one which an engineer could ever bring himself to admire. At Belfast the simple expedient of running the dynamos as motors off the station batteries, or other engines when any are running, is resorted to, the dynamos thereby running the

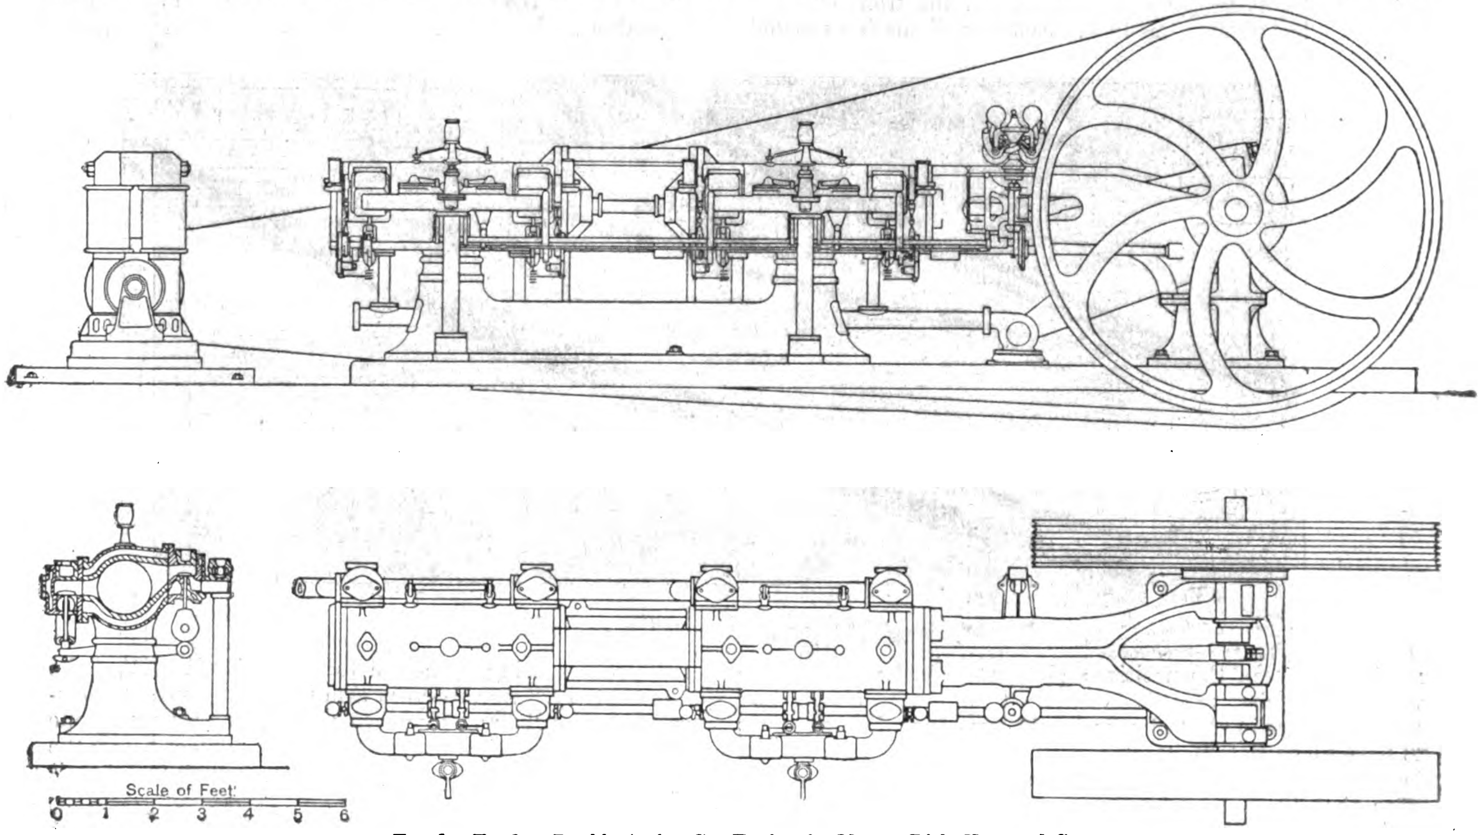

Fig. 4.—Tandem Double-Acting Gas Engine, by Messrs. Dick, Kerr and Co.

engines until the proper charge has been drawn into the cylinders and compressed, when it explodes and the engine runs up to the speed controlled by the governor. The amount of current sent through the dynamo when starting-up is regulated by a hand rheostat, the hand gear for which is situated by the switch platform rail, overlooking the engine room, and the resistance frames are placed beneath that platform.

Dynamos.—The six dynamos for this station were supplied by Messrs. Siemens Bros. and Co. The four larger machines are rated at 60 kilowatts, but are normally only intended to develop about 57½ kilowatts. They are two-pole, drum-wound, shunt machines, and are designed to run at 600 revolutions per minute. Under normal working the field is regulated to give from 225 to 240 volts at this speed, but the machines can be made to develop as high as 250 volts for exceptional work.

The two smaller machines call for more detailed consideration, on account of the diversity of the work for which they are designed. These machines are both of the two-pole shunt-wound type, and each is designed to develop about 26½ kilowatts, running at 750 revolutions per minute. The armature of each of these dynamos is double-wound, each of the windings being connected to an independent commutator. Each winding develops from 110 to 120 volts, at normal speed and excitation; and there are switchboard arrangements for putting these two windings in series or in parallel. When they are in series the voltage of the machine is, of course, normally between 220 and 240 volts; but on occasion, with this arrangement, a voltage of 270 volts is developed. These machines, when run with the armature windings of each in parallel, are intended for use as balancing machines on the three-wire network.

Electric Storage Plant.—Probably one of the greatest safeguards of a gas engine station against breakdown of supply and irregularities of pressure, in the present early stage of development of this industry, is the installation of ample electric storage plant. It is unnecessary to point out the impossibility of doing this, except where a system of continuous current is used. At the Belfast station there are two large storage batteries, one for each of the two sections of the three-wire network. The arrangement of these batteries in their special room is shown in Fig. 5, which gives a perspective view of a battery room about 28ft. square. Each battery consists of 63 E.P.S. cells of the 34-K type, in lead vessels. Besides these. there is a reserve of eight "hospital" cells, or "milkers."

Battery Regulation.—Reference has already been made to a unique system of battery regulation which is in vogue at the Belfast station, and which has been designed by Prof. Kennedy and one of his assistants, Mr. B. M. Jenkin. The usual plan of entirely cutting the end cells out of circuit, on the positive or negative battery, when the pressure on one side of the system is to be lowered, has here been abandoned, every cell being retained in the circuit whatever the pressure required on the feeders. In order to regulate the pressure applied to the feeders, the end cells of the batteries which are most remote from those connected to the 'bus bars on the switchboard are put in parallel with one another—the last few cells of the two batteries being, as it were, electrically telescoped; and the number of cells on each battery thus placed in parallel with the similar cells on the other battery is made to vary with the total pressure required between the

Digitized by Google

positive and negative feeders. In addition, the point of connection of the middle wire will be shifted either towards the positive or towards the negative end—this middle wire making, of course, a contact at some point on the telescoped cells on each of the batteries—according as it is desired to give either side a greater or lesser pressure.

This ingenious method of getting over the need for removing cells from the circuit in order to regulate the pressure is more clearly explained by reference to Figs. 6 and 7. In **Fig. 6** it is supposed that the pressure of only 106 cells is

to provide that both the middle-wire contacts shall always be with cells at the same potential. This is provided for by a reliable interlocking switch gear, by which it is impossible to short-circuit sections of the batteries or to interrupt the circuits.

This switch is shown diagramatically in Fig. 8. The contacts connected to the cells in each battery on which the regulation is done are shown lying parallel to each other.

Two brushes held by a connecting cross arm connect these contacts to their respective 'bus bars lying beside them,

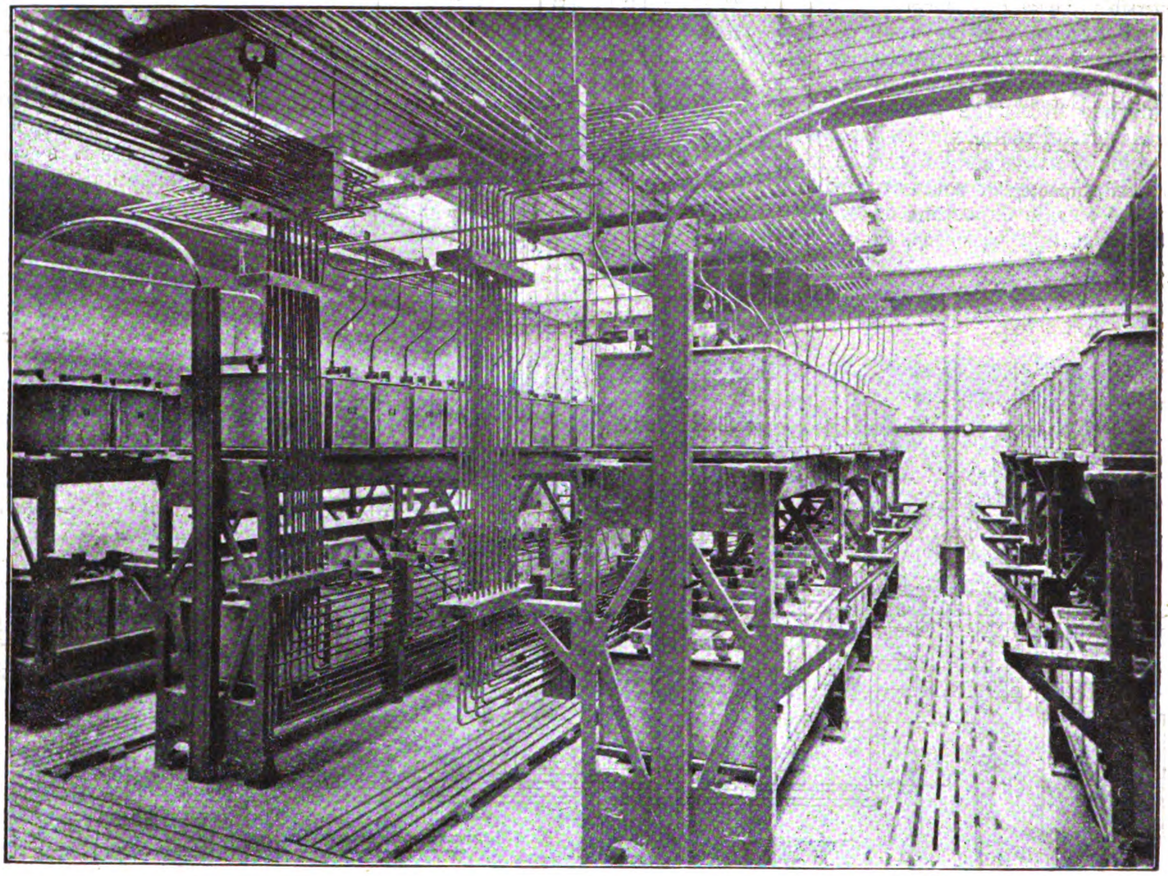

Fig. 5.—Battery Room.

required between the positive and negative feeders, and that an equal number of cells is required on the two sections. Now, there are in all 126 cells in the two batteries; so that 20 have to be put in parallel with another 20. In order to do this the cells are coupled as shown in the figure; and in order that there may be the pressure of 53 cells on each section, the middle wire must make contact with the 53rd cell of *each* battery. Now, turning to Fig 7, we suppose

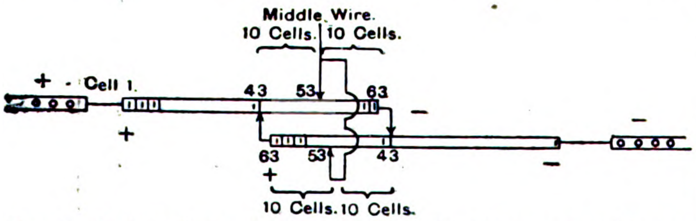

Fig. 6.—Battery Regulation. Pressure of 53 Cells on Each Side of System.

that it has been necessary to alter the balance given by Fig. 6, and that we now require the pressure of 54 cells on the positive section, and only that of 53 cells on the negative section. To obtain this, 19 cells will now be "telescoped"—instead of 20, as before—and the middle-wire contact will be with the 54th cell of the positive battery and with the 53rd cell of the negative battery, these two cells being at the same potential. In the same way adjustments can be made to give any desired pressure on either section, and it is only necessary

these 'bus bars being connected to the end cell (63) of the opposite battery. As this cross arm is moved down it "telescopes" more cells, and if moved up, fewer. By giving one of these brushes a small lead it will make contact before the other breaks, and in this way the use of pilot brushes is avoided.

The "middle" wire of the system is connected to two 'bus bars lying outside the contacts by two brushes to these same contacts. One of the middle wire brushes travels with

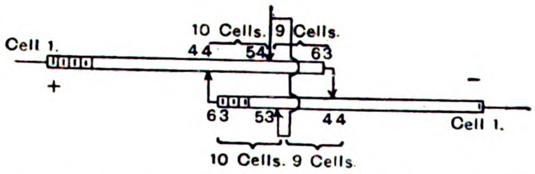

Fig. 7.—Battery Regulation. Pressure of 54 Cells on Positive Side; Pressure of 53 Cells on Negative Side.

the centre paralleling switch, while the other remains stationary.

Referring to Figs. 6 and 7, the paralleling switch moves from cell 43 to 44 in each battery, and the middle wire brush on the positive battery moves with it from cell 53 to 54. But the middle wire brush on the negative battery remains stationary on cell 53.

The paralleling brush is worked by a wheel on the front of the switchboard working a pinion geared into a rack. The

Digitized by Google

middle wire brushes are worked by being locked to the main brush, as shown in Fig. 8, by a cross bolt, which catches in a rack in one or the other. This bolt is worked by a lever on the front of the board immediately below the wheel working the main brush

The number of cells each side of the system is shown by indicators on the front the board.

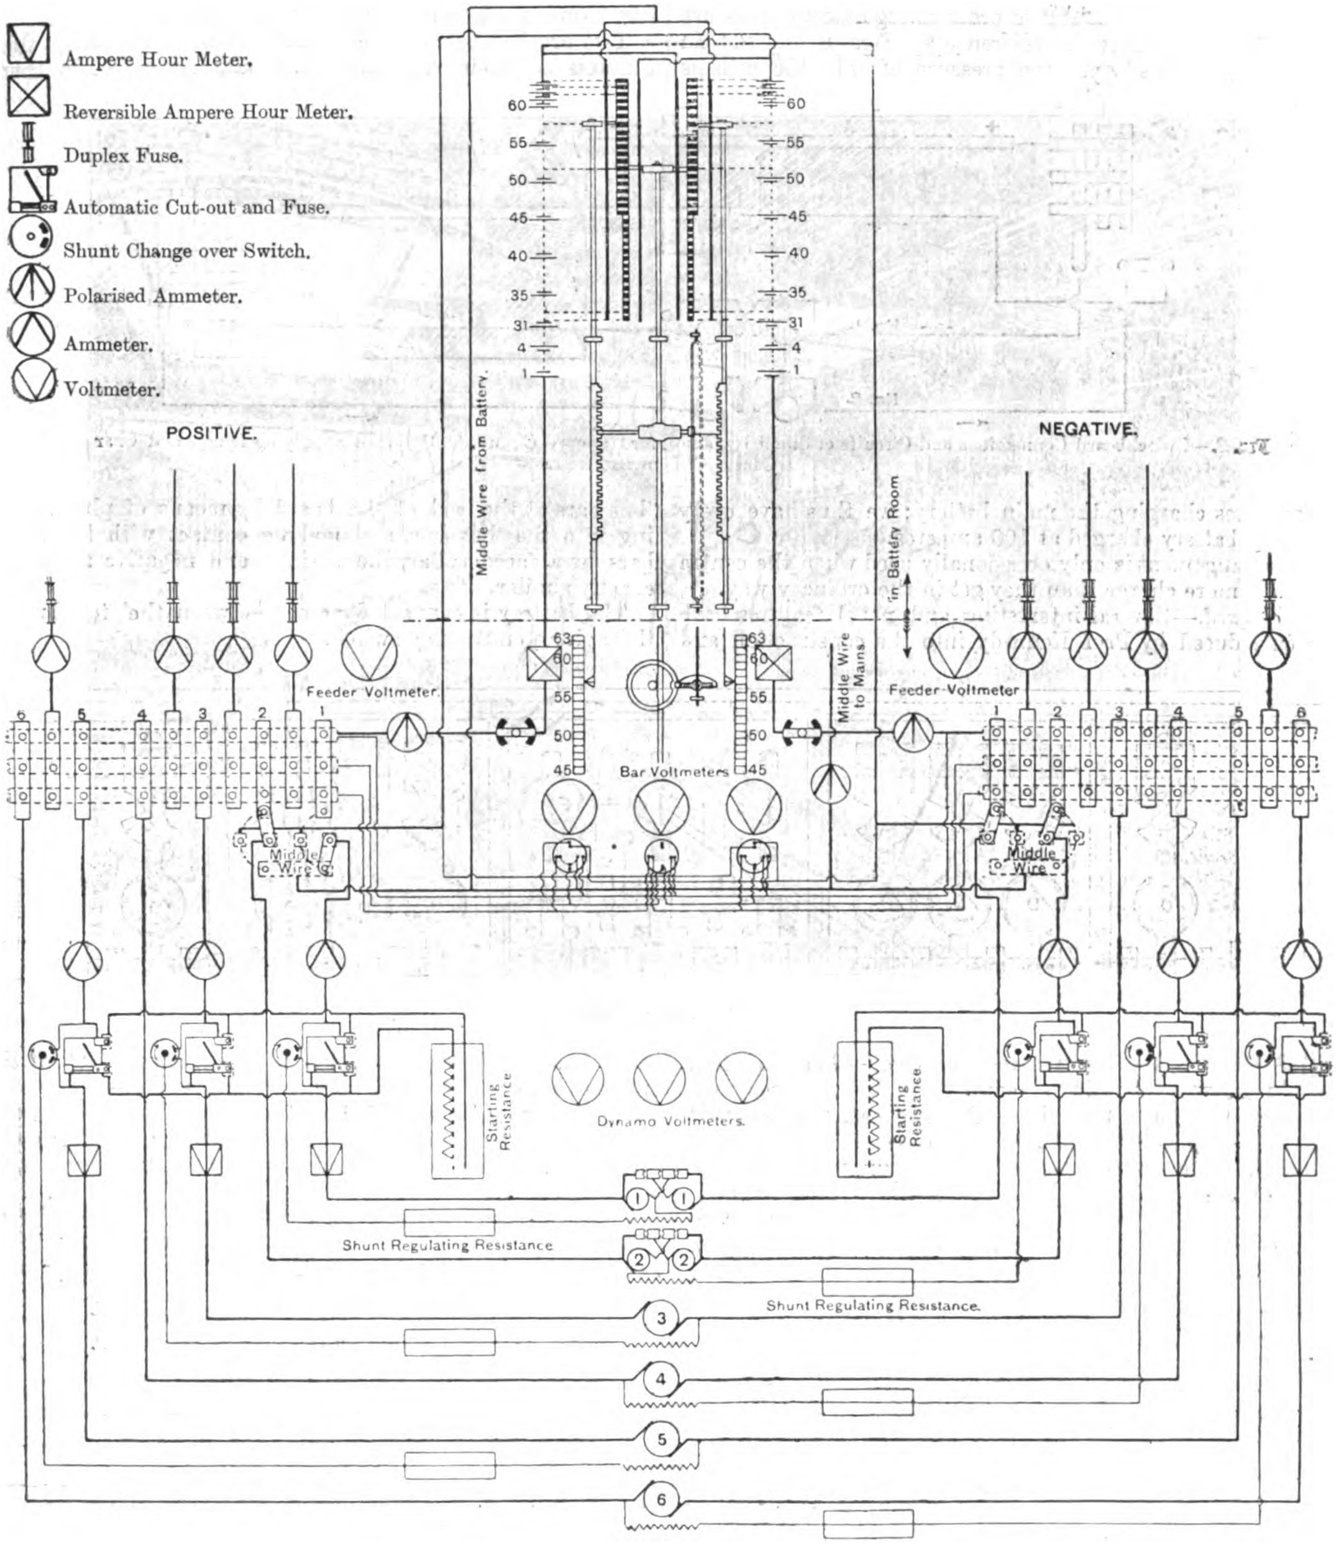

FIG. 8.—Diagram of Switchboard Connections. Portion below Horizontal Dotted Line is in Engine Room.

By setting the lever to one side or the other, and then turning the wheel one way or the other, the number of cells on circuit on either side can be adjusted.

The whole of the battery can be charged or discharged in parallel with the dynamos, the telescoped cells working at half the rate of the main battery. The telescoped cells can also be charged by themselves by altering the connections at the link switches on the small machines. This arrangement is shown in Fig. 9. Dynamo No. 1, or C, is now between the positive 'bus bar and the negative *end* of the positive battery; not between the 'bus bar and the middle-wire contact, as in Fig. 10. Similarly, dynamo No. 2, or D, is between the negative 'bus bar and the positive *end* of the negative battery. Current is going from the positive of C, by the positive feeders to the mains and lamps, back along the negative feeders, to the negative of D, from the positive of D, through the link switch to the positive *end* of the negative battery, where the current splits between the cells in parallel, charging them, then from the negative *end* of the positive battery, through the link switch to the negative of C.

The two balancing machines, C and D, can thus be run at full load on circuit and charge the centre cells at the same time.

Digitized by Google

As the load on circuit falls the current can be sent into the main part of the battery charging it, and so keeping the dynamos at full load, until the load on circuit has dropped to half that of the small machines, when 100 amperes would be going out on circuit, and 100 into the main battery. As the current on circuit splits equally between the centre cells we have 50 amperes due to it, and also 50 each side due to the four negative, and one middle wire. The board consists of five slate panels, the two outer ones carrying the "'bus" bars and feeder and dynamo bars, and the centre panel the battery regulating handle, switches, and ammeters; also the middle-wire ammeter and the feeder and bar voltmeters.

The dynamos and feeders are connected to vertical bars on the front of the board. These bars can be connected to the

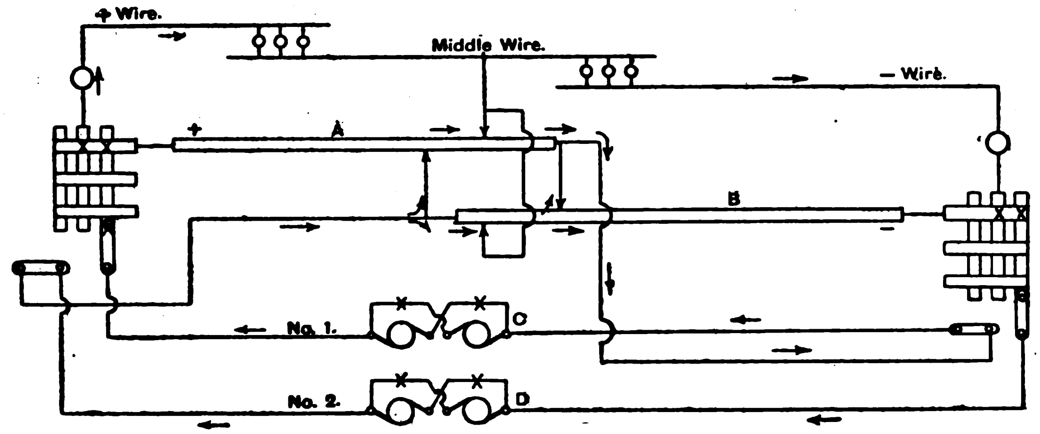

Fig. 9.—Switchboard Connections and Circuits of Small Dynamos, for "Looped Circuit." Dynamos Supplying Lamps and Charging Centre Cells of Batteries.

100 amperes charging the main battery; we thus have every cell in the battery charged at 100 amperes.

This arrangement is only occasionally used when the centre cells want more charge than they get in the ordinary way.

Switchboard.—Several interesting and novel features have been introduced by Prof. Kennedy into the construction and 'bus bars at the back of the board by means of plugs, screwing into the 'bus bar, and making contact with the vertical bars by a faced collar, the positive and negative sides being exactly similar.

The battery is connected across between the top 'bus bars through an emergency switch.

manipulation of the switching gear for the dynamos and batteries at Belfast. A front elevation of the switchboard is shown in Fig. 11, and the diagram of circuit connections is given in Fig. 8. The switchboard at present is arranged for the working of six dynamos and eight feeders, four positive and

The leads from the dynamos are connected on one side direct to a vertical bar, and on the other through an automatic (minimum current cut-out) switch and ammeter to the other vertical bar. In the case of the small dynamos, which are used either at 220 volts or 110 volts for balancing, there

Digitized by Google

is in each lead a link switch, which can be connected by means of a plug to three different places.

When pointing up, the link connects the lead to the vertical dynamo bar, when horizonal to the middle wire, and when down to the "charging circuit," which is described below.

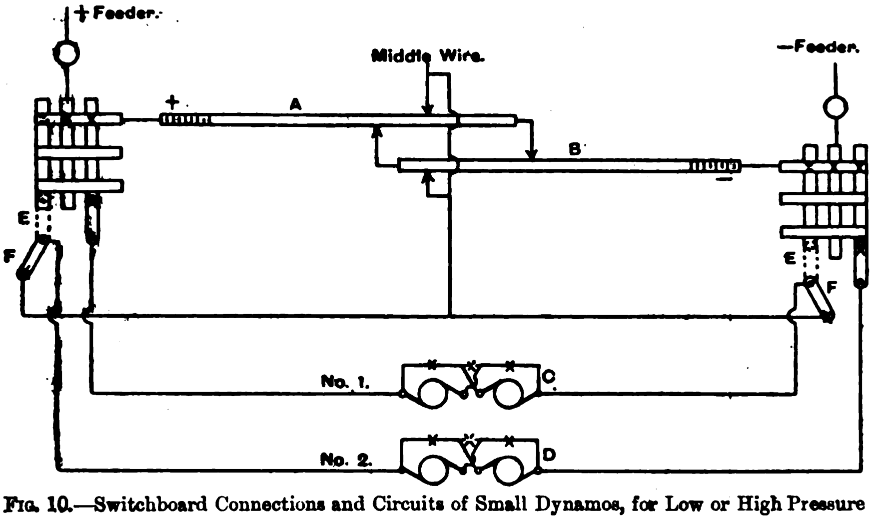

FIG. 10.—Switchboard Connections and Circuits of Small Dynamos, for Low or High Pressure

As already described, the double-wound armatures of these small dynamos can be put either in series or parallel by means of blocks and plugs, as shown diagrammatically in Fig. 8.

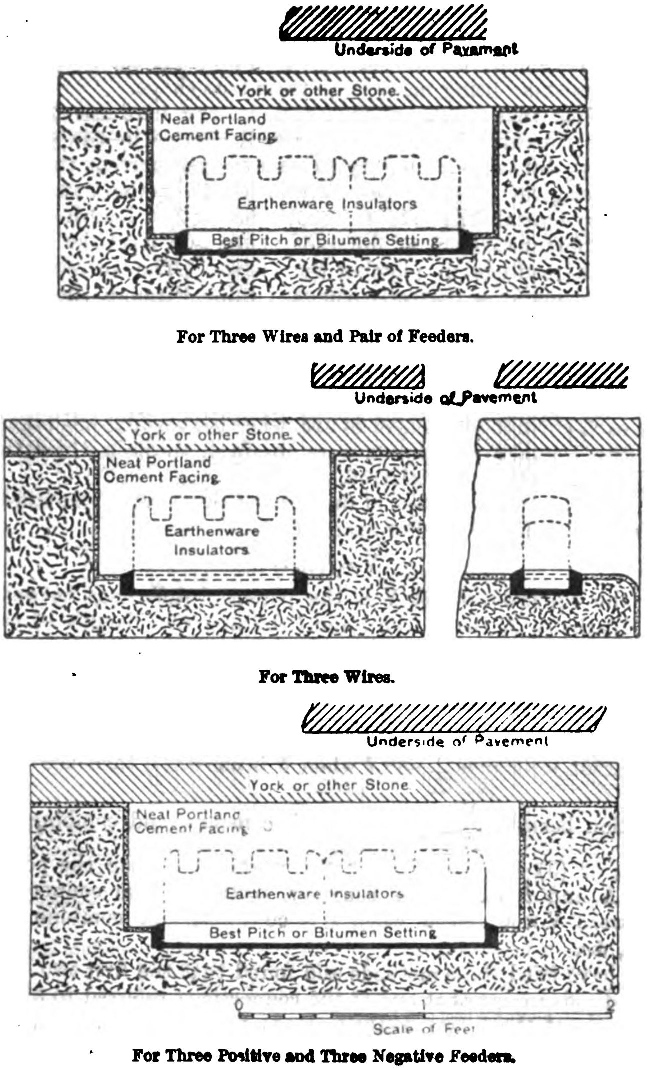

FIG. 12.—Three-Wire Bare Copper Strip Conduits.

When used as balancing machines at low volts, the connections are as shown in Fig. 10. The two machines are shown at C and D, the dotted portion of this part of the drawing representing the alternative connection of the armature windings, for putting these windings in series. Machine No. 1, or C, is shown on the positive side of the system; and machine No. 2, or D, is balancing the negative side. Across the mains are the two storage batteries, A and B, with the unique middle-wire connection, which will be described later. The switchboard connections, in this case, would be as shown at F. If now it is desired to use these machines as high-pressure generators, in parallel with the larger machines, on the 'bus bars, or when no larger machines are running, this will be done by arranging the switchboard connections as shown by the dotted connection E. The two machines will then be running at high pressure in parallel on the 'bus bars; but it is, of course, possible to use only one machine in this way, the other being out of circuit, or running on whichever side is out of balance.

To start the gas engines by means of the dynamos, run as motors, they must first be excited; this is done by plugging the vertical dynamo bars of the machine to be started on to the 'bus bars connected to the battery; the automatic switch being open. The shunt change-over switch is then turned in the direction indicated by the arrow (Fig. 8) until the brush is on the top of the two contacts on the right side of the switch. This contact is connected above the automatic, and is therefore "alive," and the current passes through the switch and the field winding to the negative pole of dynamo (considering dynamo 8). This excites the dynamo. The brushes can be put down without short-circuiting across the board, as the automatic switch is open.

A starting resistance is now connected across the open switch by means of two plugs. A switch on this resistance allows the current to be gradually increased from zero to the maximum required for starting the engine. As soon as the engine has got the first two or three explosions, the resistance is put in, and the starting current cut entirely off. The engine is then run up to speed, the volts being regulated by a resistance in the field winding until they are the same as the volts between the 'bus bars on to which the dynamo is plugged.

The automatic switch can now be closed, and the dynamo run in parallel with the battery. The shunt change-over switch is interlocked with the automatic, so that as the latter is closed the former is turned from the top to bottom of the two contacts. The lower contact is connected on the dynamo side of the automatic, and is at the same potential as the upper contact as soon as the "automatic" is closed, the brush bridging the gap as it passes over. Should the automatic now open, the dynamo is connected as a simple shunt machine, and is no longer separately excited. By this means all the difficulty of breaking the field circuit usually necessary in a separately-excited dynamo is avoided.

Mains.—The feeding and distributing mains are chiefly of bare copper strip, arranged in concrete conduits and supported on porcelain insulators; but, where the mains cross streets, or in some of the narrow streets, or again, in some places where the boggy nature of the soil makes bare copper distribution difficult and risky, covered cables have been laid down. These cables were made by the Callender Bitumen Company. Transverse sections of the bare copper strip conduits are shown in Fig. 12, which also shows a longitudinal section of one portion. The arrangements of the porcelain insulators for carrying either the three wires, or the three wires and a pair of feeders, will be clearly seen in these drawings. Belfast lies very largely upon a swampy or boggy soil, and this fact has had to be taken account of in the design of the conduits and street boxes, as well as in the arrangement for inspection. There is a small screw plug in each of the street box covers, and each man who goes the round of inspection carries with him a small portable pump and a gauge stick. With the latter instrument, which he inserts into the box after unscrewing the plug, he can gauge the accumulation of water in the box; and with the hand pump he can clear it out.

The whole of the work has been carried out under the superintendence of Prof. Kennedy and his chief assistant, Mr. Burstall; Mr. Victor A. H. McCowan, who was appointed electrical engineer to the Corporation in April, 1894, acting as resident engineer.

In conclusion, we have to express our indebtedness to and to thank Prof. A. B. W. Kennedy, F.R.S., and his assistants; also Mr. Victor M'Cowan, the chief resident engineer, and Messrs. Dick, Kerr and Co., for their kindness in placing so much information at our disposal, and in assisting us in every way to make our account of the Belfast station complete.

THE ELECTRIC ARC.

BY HERTHA AYRTON.

(Continued from page 616, Vol. XXXIV.)

When beginning to study electric arcs on my own account, it appeared to me that it would be better to avoid the complications arising from the use of cored carbons, and to study the problems under their simplest conditions by employing none but solid carbons. Accordingly, my experiments have been conducted with solid carbons for both positive and negative, the positive carbon being 11mm. and the negative carbon 9mm. in diameter in all cases.

The make of carbon employed was the "Apostle," as that had been used in all the investigations carried out under Prof. Ayrton's directions. Thus the results obtained with solid carbons can be compared with those obtained when a cored positive carbon was used.

So far my attention has been turned to three points:—

1. The true equation connecting volts, amperes, and distance between the carbons, after the potential difference had in each case reached its steady value for the particular current and length of arc employed.

2. The drop of potential difference between the positive carbon and the arc, and between the arc and the negative carbon.

3. The real shape and size of the arc as distinguished from its visible shape and size.

In the present article I propose to deal with the equation I have obtained connecting volts, amperes and length of arc, when the potential difference has reached its steady value for each particular current and length of arc.

Having found it a very tedious and lengthy process, in former experiments, to obtain a steady potential difference with small currents, I started by using only currents of 5 amperes and upwards, and found the steady potential difference that would send each current through lengths of arc varying from 1mm. to 7mm. The currents used were 5, 8, 10, and 14 amperes respectively, the largest current that did *not* cause hissing for each length of arc, and two or three of the currents that did cause hissing; I then proceeded to draw curves connecting potential difference and current for the various constant lengths of arc, similar to those in Figs. 4, 5, and 6 (pp. 336 and 337, *The Electrician*, January 18th).

On attempting, with the data thus obtained, to find an equation that would fit all the curves, to my dismay I discovered that there were *two* equations, either of which might be correct, since all the curves could be deduced with a very fair amount of accuracy from each of them. One of these was the equation to a series of ellipses, the other the equation to a series of hyperbolas. If the curves were really ellipses, no current of less than about 4 amperes ought to be able to maintain an arc continuously with the carbons used; whereas if they were hyperbolas, any current, however small, ought to maintain an arc, provided a large enough potential difference could be supplied.

Now the difficulty, already alluded to, that had always been found in maintaining small currents, made it appear as if the ellipse equation were the correct one; for it seemed possible that, although these currents could be maintained for a short time after striking the arc, or changing the current from a larger to a smaller one, yet that when the excess of loose carbon supplied in the previous state was exhausted, the remaining supply, kept up by the small steady current, would be insufficient to maintain the arc, and so it would go out. As a matter of fact, it had been found in former experiments that the arc *did* go out again and again after small currents had been flowing for a short time.

It became necessary, therefore, to find out whether the conditions of the E.M.F. of the dynamo and the resistance of the circuit were such as to cause this instability, or whether it really was impossible with the size of carbons I was using to maintain an arc, with less than about 4 amperes, for a sufficient length of time for the potential difference to reach its steady value.

Using a dynamo producing a potential difference of about 150 volts between its terminals, and a large resistance in circuit, I found that currents of 2 amperes *could* be kept flowing long enough for the potential difference to become perfectly steady, although, with such small currents, the carbons took between one and two hours to form, and therefore the potential difference took the same length of time to become steady.

Thus it was evident that the curves were not ellipses. It remained to prove whether they were really hyperbolas, or only fairly close approximations to hyperbolas; whether, in fact, there was not some extra term in the true equation which remained too small to be noticed with currents of 5 amperes and upwards, but which would be large enough, with smaller currents, to show some discrepancy between the curves and the equation I had obtained. It seemed advisable, also, to determine a great many more points on the curves experimentally than I had hitherto done. I therefore decided to make an entirely new set of experiments, using the same apparent lengths of arc as before, but taking many more currents, and beginning with 2 amperes, so that the points on the curves should be so numerous as to preclude the possibility of any mistake being made as to their true shape.

Finding that a slight difference in the hardness of the carbons caused a corresponding small change in the steady potential difference necessary to send a given current through an arc of given length, I generally took two or three readings of the potential difference for each current and length of arc, with different carbons, at different times, and used the means of these readings in plotting the curves. The current was kept flowing at a perfectly constant value through the given length of arc for periods varying from a quarter of an hour for large currents to nearly two hours for very small currents, before each reading was taken, so that there might be no doubt as to the potential difference having reached its final steady value for each current and length of arc, when the reading was taken. In this way the 137 points were obtained, through which the curves in Fig. 33 were plotted.

There are various ways of finding the equation to the family of curves in Fig. 33. For example, if

$$V = f(A, l)$$

be this equation, where V is the potential difference between the carbons, A the current, and l the apparent length of the *silent* arc as measured on the projected image, we may (1) begin by finding the connection between V and l when A is constant, then the connection between V and A when l is constant, and combine the two; or (2) first find the connection between the apparent resistance $\frac{V}{A}$ and l when A is constant, then the connection between $\frac{V}{A}$ and A when l is constant, and combine the two; or (3) start by finding the relation between the power $V \times A$ and l when A is constant, next find the connection between $V \times A$ and A when l is constant, and combine the two, &c.

I have tried these methods and found that the first two have the disadvantage that one of the connections referred to above in each of these two methods leads to a non-linear law, and therefore its exact form cannot be easily ascertained. In fact it was by using the first of these three methods that I was erroneously led to the equation of an ellipse as being the equation connecting V, A and l.

If, however, we employ the third method, and plot curves connecting *power* and apparent length of arc for various

Digitized by Google

constant currents, we obtain the series of *perfectly straight lines* seen in Fig. 34. And again, if we plot curves connecting *power* and current for various constant lengths of arc, we also obtain a series of *perfectly straight lines*, two of which are seen in Fig. 35.

In the case of carbons the positive of which was cored, it was found by the students working under Prof. Ayrton in 1893 that the curves connecting *power* and current for various constant lengths of arc were straight lines when the current was not less than about 5 amperes. With the *solid* carbons that I used, on the other hand, these lines are quite straight for all currents—even the smallest that I have tried, viz., one of 2 amperes.

As already stated, alm st every point in Fig. 33 represents the mean of several results obtained at different times with different pairs of carbons. But the curves in Fig. 33, having been drawn through the *average* position of these mean points,

W_0 be the power in watts that would be expended in sending the same current through an arc of 0mm., as shown by the curve, and

W_7 be the power in watts expended in sending the same current through an arc 7mm. long.

Then, by similar triangles,

$$\frac{W - W_0}{l} = \frac{W_7 - W_0}{7}. \quad . \quad . \quad . \quad . \quad . \quad (1)$$

This, therefore, is the general equation to the lines in Fig. 34. To obtain the equation to any particular line, W_0 and W_7 must be replaced by their actual values in the particular curve.

To give an instance. Take the equation to the line for a constant current of 6 amperes. In this case

$$W_7 = 406,$$

and

$$W_0 = 245.$$

Both Carbons Solid.

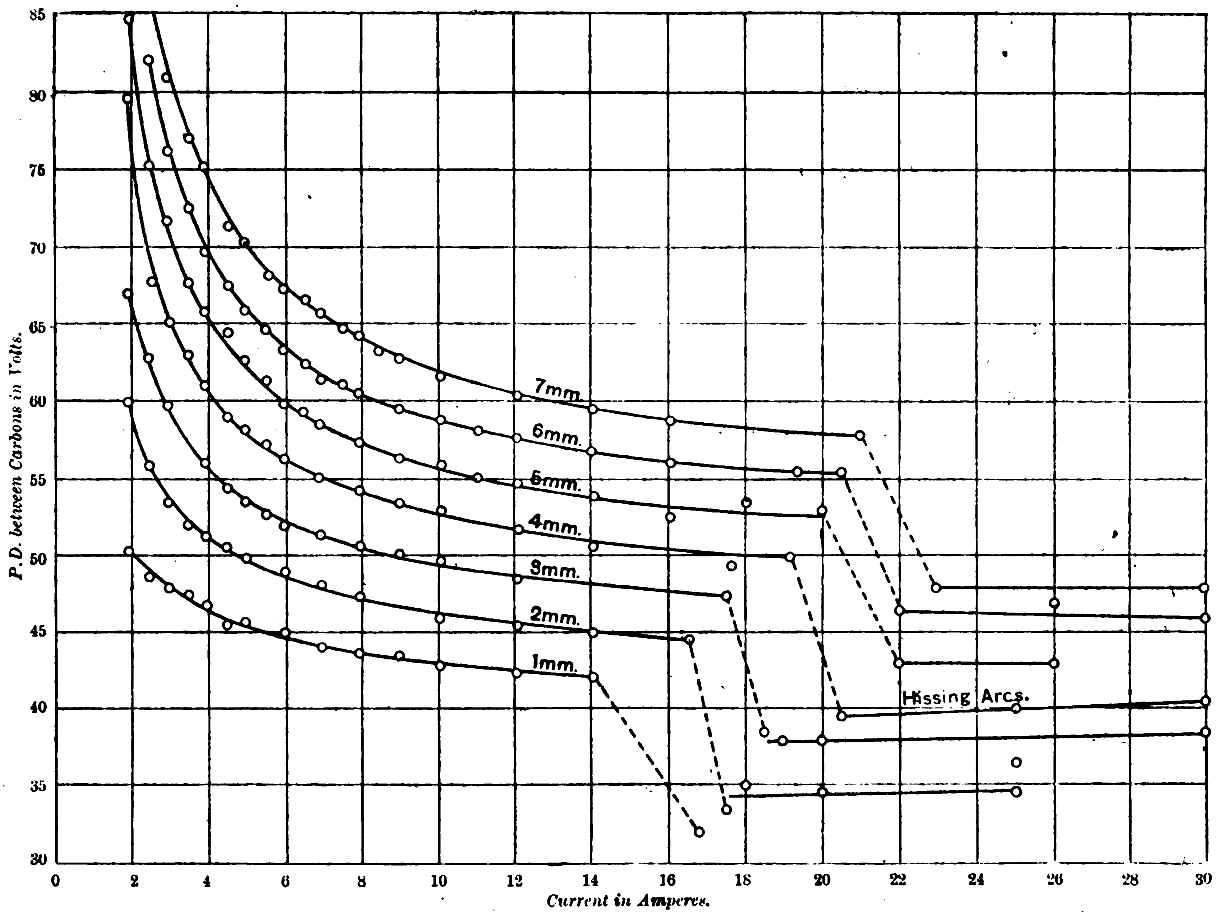

FIG. 33.—P.D. and Current for Different Lengths of Arc. Carbons :—Positive 11mm., Negative 9mm.

give still more accurately than the points themselves the ordinate corresponding with any given abscissa, *i.e.*, the number of volts corresponding with any given number of amperes. Hence, to obtain the number of watts for each point in Fig. 34, points were taken that were actually on the curves in Fig. 33, and the number of volts represented by their ordinates was multiplied by the number of amperes represented by their abscissæ. And it is because greater accuracy was obtained in this way that the points lie so well on the straight lines in Fig. 34. The ordinates of points in Fig. 35 were taken direct from the lines in Fig. 34.

From Figs. 34 and 35 we can ascertain the exact form of the general equation

$$V = f(A, l)$$

connecting the potential difference between the carbons with any current and any apparent length of arc. For, in any one of the curves in Fig. 34, let

l equal the apparent length of the arc in millimetres,

W equal the power in watts expended in sending a given current through an arc l millimetres long,

Therefore we have,

$$\frac{W - 245}{l} = \frac{406 - 245}{7},$$

$$= \frac{161}{7},$$

$$= 23.$$

Hence $W = 245 + 23\,l$ is the equation to the line representing the connection between power in watts and apparent length of arc in millimetres for the constant current of 6 amperes.

But in order to apply equation (1) to any of the lines in Fig. 34 we must know the two constants for that line, W_7 and W_0, and, as there are 11 such lines, it would be necessary to have 22 constants for those 11 lines. In order to get the complete equation, therefore, we must find some relation between all these constants.

Now the relation between W_7 with one current and W_7 with another current is simply the relation between power in watts and current in amperes for a constant length of arc of 7mm. Hence the next thing to be done was to find the law connecting

Digitized by Google

power with current for various constant lengths of arc. This law, as already explained, is, I find, a strictly linear one for solid carbons, and in Fig. 35 are given the straight lines for a 7mm. arc and for a 0mm. arc, which are the only two cases required in the present investigation.

The upper straight line in Fig. 35 for an arc of constant length of 7mm. cuts the axis along which current is measured at a distance from the zero point which represents 1·6 amperes.

Therefore, calling A the current in amperes, and using the notation already adopted for W, we have by similar triangles

$$\frac{W_7}{A+1{\cdot}6} = \frac{\text{the watts corresponding with a current of 14 amperes}}{14+1{\cdot}6}$$

$$= \frac{833}{15{\cdot}6},$$

$$= 53{\cdot}397;$$

or $$W_7 = 53{\cdot}397\,A + 1{\cdot}6 \times 53{\cdot}397,$$

$$= 53{\cdot}397\,A + 85{\cdot}435.$$

Hence $$W_7 = 53{\cdot}397\,A + 85{\cdot}435 \quad . \; . \; . \; . \; . \; . \; . \quad (2)$$

is the equation to the upper line in Fig. 35.

Using the same notation for the lower curve, and remarking that it cuts the axis of current at a distance from the zero point which represents a current of 0·3 ampere, we have

$$\frac{W_0}{A+0{\cdot}3} = \frac{\text{the watts corresponding with a current of 14 amperes}}{14+0{\cdot}3}$$

$$= \frac{556}{14{\cdot}3},$$

$$= 38{\cdot}881;$$

or $$W_0 = 38{\cdot}881\,A + 14{\cdot}3 \times 38{\cdot}881,$$

$$= 38{\cdot}881\,A + 11{\cdot}664.$$

Hence $$W_0 = 38{\cdot}881\,A + 11{\cdot}664 \quad . \; . \; . \; . \; . \; . \; . \quad (3)$$

is the equation to the lower line in Fig. 35.

Substituting the above values for W_7 and W_0 in equation (1) we have

$$\frac{W-(38{\cdot}881\,A+11{\cdot}664)}{l}$$

$$= \frac{53{\cdot}397\,A+85{\cdot}435-(38{\cdot}881\,A+11{\cdot}664)}{7},$$

$$= \frac{14{\cdot}516\,A+73{\cdot}771}{7},$$

$$= 2{\cdot}074\,A + 10{\cdot}54.$$

Therefore $$W = 38{\cdot}881\,A + 11{\cdot}664 + l\,(2{\cdot}074\,A + 10{\cdot}54)$$

is the general equation connecting the power expended in a silent arc in watts, the current flowing in amperes, and the apparent length of the arc in millimetres for the *solid* carbons which I have used. But $W = A\,V$, therefore, dividing both sides of the preceding equation by A, and omitting the fifth significant figure, we obtain

$$V = 38{\cdot}88 + 2{\cdot}074\,l + \frac{11{\cdot}66 + 10{\cdot}54\,l}{A} \quad . \; . \; . \; . \quad (4)$$

This is the equation which we have been seeking, to the family of curves in Fig. 33, and it enables us to calculate V, the potential difference in volts that it is necessary to maintain between a pair of *solid* carbons of the size and hardness that I used, in order that a current of A amperes may flow through a silent arc whose apparent length, as measured on the projected image, is l millimetres.

In order to see how nearly this equation actually represents the curves in Fig. 33, I have used it to calculate the potential difference that should correspond with currents of 3, 4, 5, 6, 7, 8, 9, 10, 12, 14 amperes, and in some cases with currents of 2 and 16 amperes for all the arcs from 1mm. to 7mm. in length; and in Table VIII. are given the results of 81 such calculations, as well as the actual potential differences taken from the curves themselves.

An examination of this table shows that 59 out of the 81 calculated values of the potential difference do not differ by as much as 0·05 of a volt from the values of the potential

difference taken from the curves, while of the remaining 22 values

7 differ by 0·05 to 0·15 volts from the curve values,
5 differ by 0·15 to 0·25 volts " "
4 differ by 0·25 to 0·35 volts " "
4 differ by 0·35 to 0·45 volts " "
1 differs by 0·8 volt " "
1 differs by 1·5 volt " "

so that only two of the 81 calculated values differ from the curve values by as much as 0·5 volt, and, since these two values, viz., one belonging to a current of 2 amperes with an arc of 1mm., and the other to a current of 3 amperes with an arc of 7mm., are on the steepest part of the curves, the wonder is, not that there are two values somewhat wrong, but that the agreement between the calculated and the curve values of the potential difference should be so marked for all the other points even in the steep parts of the curves. For it must be remembered that a slight mistake either in the reading of the currents or of the length of the arc makes a large error in the potential difference when the current is small.

There can be no doubt, then, that equation (4) *accurately* gives the law connecting potential difference, current, and apparent length of arc for solid carbons of the size and hardness that I have used.

The general form of this equation is

$$V = a + bl + \frac{c + dl}{A},$$

which may be written

$$A\{V - (a + bl)\} = c + dl. \quad . \quad . \quad . \quad . \quad . \quad (5)$$

Now this is the equation to a *rectangular hyperbola* when l is constant, and the asymptotes are—one the axis along which potential difference is measured, the other a line parallel to the axis along which current is measured. Hence the curves in Fig. 33 are a series of rectangular hyperbolas having one asymptote in common, which is used as the axis of potential difference, while their other asymptotes are lines parallel to the axis of current and at a distance from it depending upon the value of l. In fact, if d be the distance of the asymptote of any one of the curves from the axis of current, then

$$d = a + bl,$$

$$\text{or } d = 38{\cdot}88 + 2{\cdot}074\,l,$$

where l stands for the number of millimetres in the apparent length of the arc, and the unit of length for d is the length that has been arbitrarily taken to represent a volt in drawing the curves in Fig. 33.

These curves have not the appearance of rectangular hyperbolas, but that arises from different units of length having been taken to represent a volt and an ampere. In Fig. 36 I have therefore redrawn the particular curve in Fig. 33 which corresponds with a constant length of arc of 5mm., and since the same length has been taken to represent a volt and an ampere in Fig. 36, the identity of the curve in this figure with a rectangular hyperbola becomes evident. The asymptotes, the axis, and the focus of this rectangular hyperbola are also indicated.

The next step is to compare my equation (4) with equations that have been previously published by other writers to connect

Both Carbons Solid.

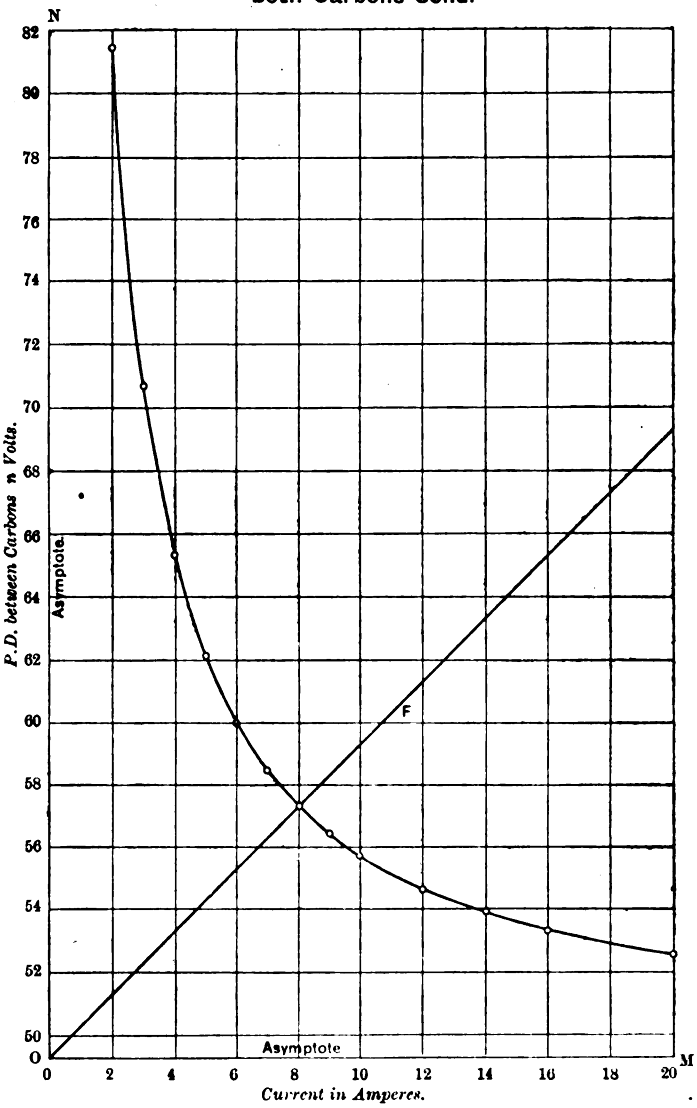

Fig. 36.—Hyperbola showing connection between Potential Difference and Current for constant length of Arc of 5mm., when Volts and Amperes are drawn to the same scale. O M, O N are the two asymptotes, O F the axis, and F the focus of the hyperbola.

the potential difference between the carbons, with the current, and the length of the arc.

ELECTRIC LIGHTING STATIONS AS FIRE RISKS.

Whether or no the cause of the recent fire at the Sardinia-street station is to become another of London's many mysteries or to be revealed in the fulness of time by the indiscretion of a subordinate or the enterprise of an inquisitive journal, we will not venture to prophesy; certain it is, however, that the thicker the obscurity with which it is sought to surround a mishap of this nature the wider the scope given to the exercise of the human imagination, especially of that of the gas man or alarmist by constitution. Indeed, so unfortunate are the effects of secrecy in matters of this kind, as in most others, that the next time the Electric Lighting Act of 1882 comes up for amendment we would suggest the introduction of a clause empowering the Board of Trade to demand an annual return of all fires occurring in central stations with a statement in each case of the origin. No doubt the space left for this particular return would, in the vast majority of instances, be left blank; so much the better. At any rate, the cause of a fire at a central station would no longer be kept as jealously from the public ear as a blotch on the escutcheon of a William-the-Conqueror family is kept from the public eye. Leaving, however, the cause of this disaster, and passing on to its effects of a reflex order, probably the most important is the rumour that the insurance companies are considering the desirability of raising their rates for electric lighting stations. Assuming for the moment that the rumour is more or less well founded, and that it is not intended merely as a warning of what may happen unless something more is done than has already been done to render electric lighting stations proof against fire, it may not be without interest to glance at what happened in the United States only a few years ago, and to see whether measures similar to those which were taken there should be resorted to in the United Kingdom.

Early in 1890, owing to the continual raising of the rates by the fire insurance companies the Electric Mutual Insurance Company was formed. At the beginning of 1891 this concern issued its first report, and a very glowing one it was too. The

Digitized by Google

causes which had led to the formation of the Company were said to be "the exorbitant rates and exacting conditions imposed by the stock companies," and it was stated that property to the value of nearly £600,000 had already been insured at an average rate of about one and one-fifth per cent., and that not a dollar of loss had occurred on any station insured. If, the report went on to say, "the experience of the Company during the first eight months, continues to the end of the first year, we shall be able to pay back to members 50 per cent. of the premium paid for their policies, and add to our reserve besides." But in January, 1892, less than two years after its sanguine start, the Electric Mutual Insurance Company handed over its entire business to the Home Insurance Company of New York. The reasons given to the policy-holders for this step were to the effect that 1891 had been one of the severest years for fire losses ever known, and owing to an unusual number of fires on electrical property the Company was losing the support of concerns which had helped it to carry on a large proportion of its insurances; West of the Mississippi, indeed, it was entirely deprived of such support. No doubt bad management and the hostility of the regular insurance companies had much to do with this *fiasco*, but, if we may credit Mr. WILLIAM BROPHY, the inherent vices of American central-station structures at that date must have been the main factor in rendering their insurance at one and one-fifth per cent. a mere philanthropic enterprise. In a Paper read before the Massachusetts Electric Light Association in August, 1893, Mr. BROPHY delivered himself of one of those sweeping utterances which are apparently intended to carry conviction by the very superfluity of their vigour. In the early days of the electric lighting business, said Mr. BROPHY, "many of those who planned or projected an electric plant seemed to totally disregard all the well-known principles of mechanical engigineering, while the architectural designs most readily adopted were those that were least adapted to economy of labour or space, and most likely to invite incipient fire and ultimate total destruction; while the idea of providing a single appliance for promptly extinguishing fires was never thought of"; Mr. BROPHY's indictment, it is true, wound up with an appeal to his auditors to make haste and insure in the Industrial Mutual Insurance Company; but his Paper contained nevertheless a sufficient number of indisputable and undisputed facts as to fires in American central stations to show that there was good cause for the New York Fire Offices to fight shy of such risks. Wooden buildings, oil soaked wooden floors, feeder-equalisers inside wooden frames, together with a total absence of hydrants and the prevalence of bad discipline would seem to afford ample justification for abnormally high rates.

Nothing of the kind, however, exists on this side of the Atlantic, and if Insurance Offices do not find electric lighting stations a particularly remunerative class of risk it cannot be on account of the number of fires. There are at the present moment over one hundred electric lighting stations at work in the United Kingdom, and so far there have only been some three or four fires. The arrangement and construction of English central stations, moreover, is very different to that which characterises, or at any rate until quite recently characterised, those erected in America. Solid single-storied buildings of brick and iron predominate, and arrangements for the extinction of fire are not forgotten. It must, however, be confessed that many a station originally well-arranged becomes in course of time overcrowded, wood is allowed to creep in where it should not, and lumber and inflammable stores are allowed to accumulate without check; main switchboards are special offenders, presenting in front an imposing stretch of slate, copper and brass, and behind a tangle of cables and plenty of match-boarding. Again, too much reliance may be placed upon fire extinction appliances. Such things are good in themselves, nay necessary, but careful periodical inspection of every nook and corner, and a design and construction having the prevention or strict isolation of fire more in view are to be preferred. If the English Fire Offices were to raise their rates unduly and unreasonably an insurance reserve fund for each undertaking, or a system of mutual insurance, would quickly checkmate them. But apart altogether from considerations connected with premiums it is not desirable that interruptions of electric supply due to fire at the generating centre should become a by no means extraordinary incident in domestic life. Whether the mishap is due to the vicinity of dangerous buildings, to bad construction of the station itself, or to lack of fire-extinction appliances, it serves all the same to connect Electricity in a quite unnecessary, quite undeserved, highly undesirable manner with Fire.

REVIEW.

A Text-Book of Mechanical Engineering. By WILFRID J. LINEHAM. (London: Chapman and Hall. 1894.)

This work is an ambitious and not altogether unsuccessful attempt to embody the principal branches of mechanical engineering in one systematic treatise. The task which the author has set his face towards is well nigh encyclopædic, and might with advantage enlist the services of many minds and fill as many volumes. But, though the perfect performance of such a task is almost, if not quite, beyond the power of any single individual, we are still inclined to believe that there are counteracting advantages in having the views and experience of one well trained mind, such as Mr. Lineham evinces, extended over this entire range of the subject of mechanical engineering, and compressed into one concise and handy volume. By the careful selection of material and an excellent choice of illustrations, the author has contrived to cover the ground in some 750 pages or less, without excessively compressing any of the items. We may here express our admiration of the illustrations, of which there are some 782, including 18 large folding plates. These are nearly all carefully drawn to scale, and in every case where it would be of use the scale accompanies the drawing. Considered only as a collection of machine drawings, it is worth while for every draughtsman to possess a copy of the work.

The book is divided into two parts, Part I. being devoted to "Workshop Practice" and Part II. to "Theory and Examples." In the first seven chapters which constitute Part I., and which together occupy about half the volume, the reader is taken the round of the shops and is shown the why and wherefore of the chief operations which take place in them. Although this section should be of use to the student in his study, as serving to give him some insight into workshop methods, it will be vastly more useful to the apprentice or, as he likes now to be called, the "articled pupil"; it cannot, of course, in any sense *replace* actual workshop practice, for no literature can do that. The following extract is made in order to give some idea of the author's method of treatment of Part I.:—

"The student will have already noticed that a good deal of judgment has to be exercised by the smith in deciding upon the length and breadth of iron necessary to execute a certain piece of work, and although this can rarely be achieved with very great nicety, yet practice enables him to guess it with sufficient accuracy. As a rule the cubic contents, or the weight of stuff should be about the same in the rough as in the finished piece, some allowance being made for burning away in the fire; but it is best to err by having too much than too little, and in most articles the extra stuff can very easily be cut off. Some, however, require more exact measurement, as, from the nature of their construction, the after-cutting cannot well be resorted to. Wherever parts have to be afterwards machined, extra material should be allowed, say from one-sixteenth to one-eighth of an inch, but the careful smith will always leave as little as possible, and if he is directed to finish *black* he should make the work as exact to dimensions as his tools will allow."

Digitized by Google

A lengthy chapter is the one devoted to "Boiler Making and Plate Work," which concludes Part I. Some attention is here paid to electric welding, the methods of using the Thomson-Houston and the Bernardos processes being described. The author believes that "the great advantage of electric welding lies in the local character of the heating, which prevents the spoiling of a finished piece of work." This is undoubtedly one of the advantages where certain kinds of work are required to be done; but we think that there are other advantages of still greater importance. Nor is excessive localisation of heat in boiler welding a thing always to be desired.

In Part II. a great diversity of subjects receive consideration. The section commences with a chapter on "Strength of Materials, Structures and Machine Parts." Testing machines receive very adequate and clear description, and a good general account of ordinary testing is included in this chapter. This chapter, we think, would be rendered more complete by the addition of a short account of the stresses in, and the strength of, flywheel rims—an important matter, which is far from being correctly treated except in the very latest editions of one or two of the text-books now in the hands of students. After a few lessons in theoretical mechanics, the student is led on to the study of the various methods of transmitting power to machines, and space is even devoted to a short study of electric transmission. The chapter dealing with these subjects is probably the most compressed of all; but it should be serviceable as an introduction to the study of larger and more complete works. Chapter X. covers the ground of "Heat and Heat Engines," and is followed by the concluding chapter on "Hydraulics and Hydraulic Motors." We do not care for the author's definition of heat as "a 'pendulum' motion of the molecules." It is inexact, and conveys two erroneous notions. The form of the motion is not that of an ordinary pendulum; nor is it the motion, but the energy of it, which is a measure of the heat. A short account of the thermodynamics of heat engines affords a useful introduction to Chapter X., and does not tax the mathematical abilities of the reader to any great extent. A rather loose and imperfect statement of the important second law of thermodynamics does not seem to affect the subsequent interpretation of this law in its relation to heat engines; and the author, if not quite as explicit and clear as might be desired, has at any rate rendered this part of his work free from the erroneous views on thermodynamics which are affected by a certain class of engineers. Steam engine valve quantities and valve gears receive very thorough treatment; and there is a series of well-illustrated descriptions of the principal types of this engine. Boilers, the construction of which receives such extensive notice in Part I., are in Part II. absolutely ignored. Indeed, the most serious defect of Chapter X., if not of the whole book, is the absence of information about steam generation and generators, from the point of view of their action and practical working. Not quite two pages on the chemistry of combustion, a short paragraph on forced draught and a still shorter one on fuel waste, are all that is afforded on this important subject. About six pages are devoted to the gas engine, some five of these being allotted to a description of the "Simplex" engine. A few pages on the Priestman oil engine bring the chapter to a close. The section on hydraulics needs no further notice than to say that what there is of it is very good, but that it is all too brief for more than a cursory treatment of such a subject. The work is provided with a good index, and it should be welcomed by the budding mechanical engineer as a practical and reliable text-book.

ON THE INVESTIGATION AND DESIGN OF ALTERNATE-CURRENT DYNAMOS.

BY DR. H. BEHN-ESCHENBURG.

The factor which best shows the quality and efficiency of an alternate-current dynamo is the fall of potential, *i.e.*, the difference between the terminal E.M.F. of the dynamo at constant speed and constant exciting current when the armature is on open circuit and when it is conducting a current of any given phase difference. In other words, what is meant by the fall of potential of a machine is the difference of the potentials of the machine at constant excitation and speed at no load and at a fixed load. The fall of potential is generally determined (1) by the self-induction of the armature; (2) by the copper resistance of the armature; (3) by the reaction of the eddy currents induced by the armature currents mostly in the solid iron masses of the field magnets. These three factors, which determine the fall of potential, may be represented as electromotive forces, with certain phase lags, producing with the E.M.F. of the dynamo the terminal potential. The three electromotive forces in the armature are proportional to the load current (*Belastungsstromstärke*), and may be represented in the well-known polar diagram (Fig. 1) in their effective values and phases or directions by e_1, e_2, e_3. In the same diagram I represents the armature current, *i.e.*, the load current of the dynamo; E is the potential of the dynamo running at open circuit. The directions of the different quantities will be fixed by the angle of the phase difference between the quantities in question and the current I. By the nature of things there exists between the E.M.F. e_1 of self-induction and the current I the phase difference $\frac{\pi}{2}$, and between the E.M.F.'s e_2 and e_3 and the current the phase difference 0. We assume further that with the load selected for the dynamo there exists between the potential E_1 and the current strength I the phase difference ϕ, defined by the relation of the watt output W and the apparent volts-amperes in formula 1—

$$W = E_1 I \cos\phi \qquad (1)$$

For lighting transformers ϕ is about 10deg., and cos ϕ practically $= 1$; for distribution of power in non-synchronous

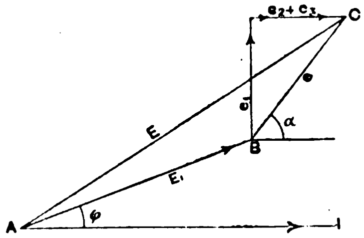

FIG. 1.

motors ϕ is about 35deg., and cos ϕ about 0·85. The fall of potential may be taken from the diagram and equals $E - E_1$. The same diagram may be used for synchronous motors, when the E.M.F. of the motor is taken in place of the terminal potential E_1 of the generator and *vice versâ*.

The resultant e of the three electromotive forces e_1, e_2, e_3, which has a phase difference α from the current I, represents the total counter electromotive force of the loaded armature. By this E.M.F. e and the current I the apparent internal resistance or impedance R of the armature can be defined by the equation

$$R = \frac{e}{I} \qquad (2)$$

It is an important point in the investigation of alternators to ascertain and calculate in advance this impedance R or the counter E.M.F. e; these factors fixed, all others required can be easily obtained from Fig. 1.

To this end I have used for some years the following method, which I should like to recommend to fellow electricians:—First of all, the characteristic of the E.M.F. E of the dynamo with the armature on open circuit has to be taken (*see* Fig. 2, curve E). The abscissæ represent the ampere-turns of the magnetising current, and the ordinates represent the induced potential E of the dynamo at a certain speed. Another characteristic, I_0, is taken, the terminals of the armature being connected in short-circuit through an ammeter. The abscissæ, again, are the number of ampere-turns of the field, and the ordinates the current in the short-circuited armature in amperes. This curve I_0 differs very little from a straight line; for high magnetisations it is, however, a little convex.

Digitized by Google

In the case of the short-circuited armature the diagram (Fig. 1) must be altered so that $E = 0$; then we get immediately, in Fig. 3, $e = E$, and we have

$$R = \frac{E}{I_0} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

for each value of the abscissæ. These values of R we draw on the same curve diagram as ordinates, and obtain in this way a third characteristic R of the apparent resistance for each value of the field strength.

For any value of the load current I, e is given for a certain field excitation by the equation $e = R\,I$, and E_1 and ϕ can be calculated from the diagram. If, on the other hand, for a given field current E, ϕ and I are to be taken as given and E_1 has to be predetermined, or if E, E_1 and I are given

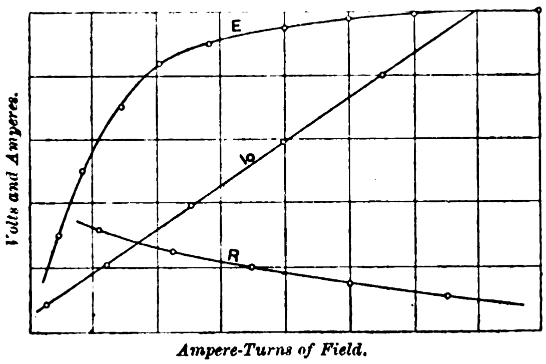

FIG. 2.

from observation, and ϕ has to be determined, the formulæ are obtained from the obtuse-angled triangle A B C of the diagram.

$$\cos(\alpha - \phi) = \frac{E^2 - E_1{}^2 - e^2}{2\,E_1\,e} \quad . \quad . \quad . \quad . \quad . \quad (4)$$

$$E_1 = -e \cos(\alpha - \phi) - \tfrac{1}{2}\,\frac{[e\,.\,\sin(\alpha - \phi)]^2}{E}. \quad . \quad (5)$$

The electromotive force e will in practice, of course, be smaller than E.

Finally, to ascertain the phase difference α between e and I_0 or I, not only has the current I_0 of the short-circuited armature to be observed, but also the watt consumption $E\,.\,I_0 \cos \alpha$, either directly by means of a wattmeter or by measuring the energy required to drive the short-circuited dynamo. In well-

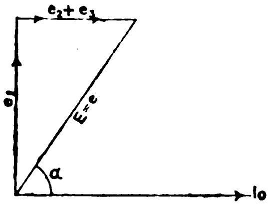

FIG. 3.

designed dynamos α is greater than 80deg., and can be taken approximately as $\frac{\pi}{2}$. This means that the loss in the copper and in eddy-currents should be very small as compared with the potential fall. The component e_2 of the E.M.F. e, since $e_2 = I\,.\,r$, is easily determined by measuring the resistance r of the armature. The component e_3 of the reaction of eddy-currents increases approximately as the square of the number of periods of the alternator, and can thus be separated from e_2 by means of observations. It is to be remarked that in most cases e_3 seems to be neglected by writers on this subject. Evidently α can be calculated when measurements at any load have resulted in values for E_1, E, I and ϕ; for instance, taking $\phi = 0$ or $\phi = \frac{\pi}{2}$ respectively when the machine is on an entirely inductionless load such as glow lamps or on a purely inductive load such as motors running empty, or ϕ may be ascertained by means of a wattmeter. It may also be remarked that for small values of ϕ—for instance, with lighting transformers—the determination of the potential fall by means of the diagram will give better results than a wattmeter measurement, as in the diagram $\sin \phi$ and with the wattmeter $\cos \phi$ is obtained.

If for approximation $\alpha = \frac{\pi}{2}$, then the formulæ (4) and (5) for E_1 and ϕ are simplified, and we get

$$\sin \phi = \frac{E^2 - E_1{}^2 - e^2}{2\,E_1\,e} \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

$$E_1 = E - e \sin \phi - \tfrac{1}{2}\left(\frac{e^2 \cos^2 \phi}{E}\right) \quad . \quad . \quad . \quad (7)$$

for the two extreme cases of $\phi = 0$ and $\phi = \frac{\pi}{2}$, we get respectively

$$E_1{}^2 = E^2 - e^2 \qquad \phi = 0 \quad . \quad . \quad . \quad . \quad (7\text{A})$$

$$E_1 = E - e \qquad \phi = \frac{\pi}{2}. \quad . \quad . \quad . \quad . \quad (7\text{B})$$

The plotting of the two characteristics E and I_0 can be done in a very short time with the assistance of a voltmeter, a continuous-current ammeter, an alternate-current ammeter, and a speed counter, and the driving of the dynamo only requires 10 to 20 per cent. of the normal load—*i.e.*, the energy which is lost in the loaded dynamo. During the short time which is required for its measurement the short-circuit current I_0 can, without hesitation, be made twice or three times the normal current. In taking the short-circuit curve I_0 the speed is a secondary matter, as naturally for a constant field magnetisation the short-circuit current remains the same for all speeds.

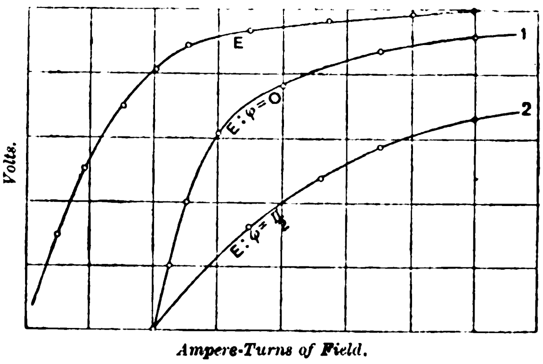

FIG. 4.

In Fig. 4 are plotted from Figs. 1 and 2 the specially calculated characteristic curves of the potential for the two limiting cases of $\phi = 0$ and $\phi = \frac{\pi}{2}$. Between these curves 1 and 2 must lie for all possible values of ϕ all the potentials of the dynamo with the current I.

Besides giving us the quantity R, this method gives us a clear picture of the conditions which determine the magnetic leakage of the field. The ampere-turns of the armature are magnetising the magnetic circuit in the same manner as the ampere-turns of the field coil. Those magnetic lines of force which are induced by one of the two coils without cutting the other coil are called lines of leakage. Let us assume that of the total lines induced by the field coil S_1 per cent., and of the total lines induced by the armature S_2 per cent. are lost due to the leakage. Let the number of windings of the field be W_1, of the armature W_2, so that both sets of windings may be reduced to the same magnetic circuit. This reduction can easily be effected by means of a diagrammatic drawing, in which the closed circuits of the magnetic lines are drawn as linear conductors analogous to a diagram of electric currents; the ampere-turns of the armature and of the field are shown as magnetomotive forces, analogous to electromotive forces at the points where the windings are cut by the lines of force. The number of the lines of force can be calculated in the same way as is done for electrical currents by means of Kirchhoff's laws. When the armature is short-circuited a balance must exist between the magnetomotive force of the armature currents and that of the field coils, excepting the ampere-turns which produce the leakage field and those which induce the E.M.F.'s

Digitized by Google

e_2 and e_3. These give the magnetomotive forces which induce the E.M.F.'s E and e_1. We get then with the important relation:

$$(1-S_1)\, i_0\, W_1 = \frac{(1+S_2)\, I_0\, W_2}{\sin \alpha} 1{\cdot}4, \quad . \quad . \quad . \quad (8)^*$$

i_0 being the exciting current in the field windings. The factor 1·4 on the right determines the maximum number of the ampere-turns from the mean value I_0.

If the field system has a single magnetising coil, then, as is easily seen, W_1 should be multiplied by half the number of poles. If the armature system consists of N phases (*Phasenabtheilungen*), then on the right W_2 must be multiplied by $\frac{N}{2}$, so that W_2 denotes the number of windings of one phase.

From equation (8), which besides the number of turns only requires the observation of the curve I_0, there is given for any field excitation the ratio of the counter electromotive force e to the E.M.F. E of the dynamo for a load current I—in other words, the percentage potential loss. We have

$$\frac{e}{E} = \frac{I}{I_0} \text{ or } \frac{e}{E} = \frac{I\, W_2}{i_0\, W_1} \times \frac{1{\cdot}4\,(1+S_2)}{(1-S_1)\sin \alpha}, \quad . \quad . \quad (9)$$

in other words, e is to E as the load current I is to the short-circuit current I_0 at the same excitation or as the number of ampere-turns of the armature to those of the field multiplied by a factor which approximates to 1·4. Further,

$$\frac{(1+S_2)\, 1.4}{(1-S_1)\sin \alpha} = \frac{i_0\, W_1}{I_0\, W_2}. \quad . \quad . \quad . \quad . \quad (10)$$

The leakage loss S_1 is easily calculated when the principal dimensions of the dynamo are known, and the above formula (10) therefore gives the value of S_2, which is otherwise difficult to calculate. The total magnetic resistance X of the magnetic circuit of the field and armature windings is calculated in the usual way from the individual resistances of the air and the iron construction at the selected density. If we denote the total lines induced by the ampere-turns of the field by B and the alternations by n, then the following equations apply:—

$$E = \frac{B\,.\,W_2\,.\,2\pi n}{1{\cdot}4 \times 10^8}\ ; \quad (11) \qquad 1{\cdot}2\, i_0 W_1 = B\, X\,(1+S_1)\ ; \quad (12)\dagger$$

also

$$1 + S_1 = \frac{5{\cdot}4\, i_0\, W_1\, W_2\, n}{E\,.\,X\,.\,10^8}.$$

For the case of the short-circuit we have $I_0\,.\,R = E$, and

$$R = \frac{7{\cdot}5\, W_2^{\,2}\,.\, n\,(1+S_2)}{X\,(1+S_1)\,(1-S_1)\sin \alpha\,.\,10^8}. \quad . \quad . \quad (13)$$

This last equation shows us the constructive importance of the apparent resistance R of the dynamo. R is proportionate to n and the square of the number of turns W_2. With higher saturations of the iron R decreases, since the magnetic resistance X increases.

In this outline I believe I have given a convenient method which furnishes direct values, and which permits of the comparison and discussion of alternators; it is a method which I have thoroughly tested in a large number of cases. With a knowledge of the two characteristics when running on no load and on short-circuit, one may predetermine for any alternate-current dynamo up to what limits the load—that is to say, up to what values of current and phase difference between current and potential a dynamo can maintain a certain terminal potential.

* The correctness of this equation is open to criticism. It is derived from the diagram Fig. 3, where $\sin \alpha = e_1/e$. Now e depends on the field magnet lines cutting the armature, or $i_0\, W_1\,(1-S_1)$ as given; the value of e_1 depending on the E.M.F. of self-induction is due to all the lines produced by the armature, or $I_0\, W_2\,(1) \times 1{\cdot}4$. The equation makes it depend on all the lines produced, including leakage, plus the leakage in addition. If this view is correct it will correspondingly modify the equations which follow.—[Translator.]

† If X denotes the magnetic resistance of the magnetic circuit carrying the lines B, which traverse both the armature part and the field magnet part, then $1{\cdot}2\, i_0\, W_1 = B\, X + B\, S_1 M$, where M is the magnetic resistance of that part of the circuit traversed by both leakage lines and lines cutting the armature; hence this equation is only true assuming the leakage path to be of the same magnetic resistance as the path through the armature coils. This will modify equation (13).—[Translator.]

FORMATION OF PERSULPHURIC ACID, AND THE CHEMICAL REACTIONS WHICH TAKE PLACE IN LEAD ACCUMULATORS.*

The apparatus used consisted in its simplest form of a beaker, in which stood a porous cell of about 100c.c. capacity. A piece of sheet lead 2mm. thick and 150 sq. cm. in area, surrounding the porous cell, served as cathode. The anode was of platinum wire or foil. The temperature was kept at 8°C. to 15°C. by cooling the beaker with ice, and in some of the experiments the cathode was placed in the porous cell in the form of a thin lead tube, through which ice water flowed. The temperature was thus kept at 5deg. to 6deg. at the anode, which in this case was a platinum wire wound round the porous pot. The theoretical yield per ampere-hour is 3·63 grammes of persulphuric acid, and preliminary experiments showed that very little persulphuric was formed by the electrolysis of solutions of sulphuric acid whose density was under 1·2. The E.M.F. was five volts, and the current density 100 amperes per square decimetre of anode surface.

The yield was largest in the first hour, and acid of density 1·450 gave the best result. When sulphuric acid is largely diluted with water, it breaks up into the ions (H) (H) (SO_4); when moderately diluted it breaks up partly into the ions (H) (HSO_4), and the more concentrated it becomes the greater is the preponderance of the ions (HSO_4). The authors consider that under suitable conditions the ions (HSO_4) give up their electric charges, and unite to form $H_2S_2O_8$ (persulphuric acid) in a manner analogous to the formation of Cl_2 molecules from the Cl ions in the electrolysis of hydrochloric acid. For the formation of persulphuric acid, however, certain conditions must be fulfilled, for the residues SO_4 as well as HSO_4 react upon water, forming H_2SO_4 and evolving oxygen. Therefore a high current density is required to compel the HSO_4 ions to combine before they meet water molecules. The yield of persulphuric acid does not increase as the density of the solution increases, but begins to fall off at a specific gravity of 1·5, partly owing to the higher resistance of the concentrated sulphuric acid, partly to its viscosity, partly also to the local warming at the anode, which causes decomposition of the persulphuric acid already formed. The yield of persulphuric acid decreases as the electrolysis is continued, being less in the second hour than it is in the first. The authors consider that their results support Küster's theory that the electrolytic formation of persulphuric acid is due to the union of HSO_4 ions, and not to oxidation, and regard Oettel's experiments on oxidation by electrolysis as confirmatory. There is a limit to the amount of persulphuric acid which can be obtained, as it, like pure sulphuric acid, is a very bad conductor, and forms an almost insulating sheath round the anode if it is produced more rapidly than it can diffuse into the surrounding liquid. The yield decreases very rapidly with rise of temperature, and at 60°C. persulphuric acid decomposes almost as soon as it is formed. The most concentrated acid the authors obtained by electrolysis contained 433·8 grammes of persulphuric acid per litre.

The authors proceed to discuss the bearing of the results of their experiments on the theory put forward by M. Darrieus, that the formation of persulphuric acid during charge converts the lead oxide and lead sulphate on the positive plate into peroxide, the completion of charge being denoted by the decomposition of any excess of persulphuric acid in sulphuric acid and oxygen with the evolution of gas. They point out that the results of their experiments are not in accord with this theory, for with the low-current densities used with accumulators very small quantities of persulphuric acid would be formed even when the acid has the unusually high specific gravity (1·3) employed by M. Darrieus. With a current density of 2,800 amperes per square metre such acid was found to give 24 per cent. of the theoretical yield of persulphuric acid; when the current density was reduced to 1,300, the amount of persulphuric acid formed could not be estimated quantitatively, and could only just be detected qualitatively. When acid of 1·15 specific gravity was electrolysed in an ordinary voltameter no persulphuric acid at all was found at a current density of 4,000; traces only began to appear when the current density was raised to 10,000. Now the current densities normally used in working accumulators are much lower than these; *e.g.*, the normal current for charging an 80 ampere-hour accumulator with positives of 20 square decimetre area would correspond to a current density of 5 amperes per square metre. The authors meet the possible objection which might be taken to their experiments, namely, that they were made with a platinum anode which might exercise a catalytic action on the persulphuric acid formed, by observing that were this the case they would have been unable to obtain solutions containing 400 grammes of persulphuric acid per litre. They further point out that lead and lead sulphate are not converted into peroxide of lead by solutions of sulphuric acid containing persulphuric acid.

* K. Elbs and O. Schonherr. *Zeits. f. Elektrotechnik und Elektrochemie*, 1895, 417-421, and 468-474

Digitized by Google

however concentrated they may be, but that a clean lead plate sulphates more rapidly in such solutions, while in the case of a plate coated with peroxide of lead, the peroxide is reduced with evolution of oxygen gas and the formation of lead sulphate. These results do not agree with Schoop's experiments on potassium persulphate. In accumulators, however, we have only to deal with solutions containing free sulphuric and free persulphuric acids, and though the authors admit that the latter can occasionally be found in charged accumulators, they regard it as only an accidental and secondary product, and that it is in no way entitled to the importance attached to it by M. Darrieus.

THE LECTURE THEATRE.*

In those early days when man first began to acknowledge the solidarity of the world and to appreciate the instruction conveyed in the conversation of his more experienced contemporaries, when books were rare, and the press undreamt of, the lecture was a most fitting means of imparting instruction. Even when printing had made the circulation of thought and learning more rapid, the price of books still left the lecture theatre an admirable and economical place for education, and a mass of notes was a valuable contribution to the student's scanty library; but in these days, when the thought and the accumulation of years of study may be bought for a few shillings, the lecture is an example of an absurd conservative adherence to an antique system which has long ceased to justify by results the favour with which it is received. When every professor publishes a text-book for the benefit of his students, containing all, or practically all, that he purposes to repeat to them during the session, and when even a superficial acquaintance with the leading journals would keep them more up to date than the interpolations in a stereotyped course of lectures do, we do not see why college authorities continue to include courses of lectures in the curriculum, and even rigidly insist upon regular attendance at them. That many professors consider their own lectures of such very little importance as to deliver them more from a sense of duty to the board than of utility to their hearers, is well known, and it is only natural to suppose that the discourses of their compeers are held in even less respect by them. The lecture is not even a satisfactory way of educating professors, to look at the subject from the Teutonic point of view. To go through the same matter in the same way, perhaps in the same words, year after year, without any clue to the real benefit that is being derived from it, is scarcely edifying to the speaker or the hearers. If the professors—we are now speaking of engineering colleges—mixed intimately with their pupils so as to gain a direct acquaintance with the difficulties which they have to face, and would take the trouble to discover whether their remarks are being appreciated at their real value or not, something useful might be done in the lecture theatre. As matters stand, however, the demonstrator is of far greater importance to the welfare of the student than the professor. To the demonstrator he talks on more equal terms, discusses his difficulties, and ventilates his opinions. It is the demonstrator who assists him at his experiments, overlooks his drawings, checks his calculations, &c. It is to be regretted that his dignified position, or his avocations, render it impossible for the professor to mingle sufficiently intimately with his students to get some idea of their individuality.

It is a disadvantage attendant on all forms of education, and unfortunately so to a remarkable degree in technical education, that while it makes many parasites, if we may use the term, it only develops the individual characteristics of those who could in all probability succeed without its assistance. The ever increasing demand for the "ready reckoner" form of technical literature is sufficient proof of the parasitism to which we refer. The book that receives the most favour on the market is that which provides cut-and-dried formulæ for everything; it is time-saving, and therefore economical, but when science has brought the simplicity of formulæ to a little greater perfection, and art has consummated the calculating machine, mathematics will become abstruse learning, willingly given over to the lucubrations of misguided students! We have too many laws, that is the truth of the matter. "It is liberty, not law, that makes great men," as Schiller said, and though he spoke of ethical law, his observation applies equally to science. Whatever a man wants to know he should discover for himself. This continual drumming of first, second and third into the ears of drowsy students makes parrots, not men, of them. If they are to be taught anything, teach them how to learn, and not how to be taught. If the laws of motion are to have any reality to them, show them how to find them out for themselves. Teach students to draw deductions, and you teach them to reason. Instil into them only other men's thoughts and other men's reasons, and you set their feet on the primrose way to ignorance. A good memory is in many cases the cloak of a poor intellect. Memory is not, as it is often taken to be, cleverness; it is the servant of ability. The wholesale dosing of roomsfull of students with lecture matter is not a good means of imparting instruction. An attempt should be made to draw out the individuality and personality of each student, a fact which Prof. Herkomer has fully recognised, and uses with success in his art school.

We ask, it will be said, for an impossibility. We admit that such is the case under the existing ridiculous conditions. Education is a great deal too cheap to be good. The number of students is entirely out of proportion to the number of instructors. The instruction is such that it develops the memory at the expense of the intelligence. It will be urged that we have lost sight of the benefits derived from the laboratory and the college workshop. By no means. We have studied both. In the former, except in isolated cases, the student is expected to complete an experiment in as many hours as there should be days. He is given a card of instructions, and follows them mechanically; he is marked by his results, and if he cannot get satisfaction from his instrument, he cooks the figures; the law that he should deduce is put in italics under his nose; he knows what the results should be before he commences observation; finally, he is not always honest, and one demonstrator is responsible for perhaps thirty to forty students. The college workshops are comparatively pleasant as a playground, fairly useful as an advertisement, occasionally handy for repairs, eminently useless for instruction. We are not dealing with these matters now, or we would justify our hard sayings. Our object is to call attention to the misdirection of energy in the lecture theatre, and to put forward the proposition that the aim of technical education should be to draw out and develop the natural abilities of students, not to coach them for examinations, nor to lay snares to draw them into the seductive slough of parasitism.

* From the *Engineer*.

THE NEW ELECTRIC SUPPLY PLANT AT BUDAPEST.

This plant, which has been lately described in German and American journals, was erected by the Austrian General Gas Company to compete with the old supply station of Ganz and Co. It supplies low-pressure continuous current, whilst the old station supplies high-pressure alternating current. Both undertakings run their mains through the same streets and districts, and consumers have the option of either current. The new Company has adopted the mixed system, that is to say, it generates high-pressure alternating current and distributes low-pressure continuous current. A two-phase current is generated at 1,800 to 1,900 volts and transformed down at the sub-station by means of rotary transformers, consisting of two-phase motors and continuous-current generators, to continuous current of 240 volts for three-wire distribution. Accumulators are provided to allow of the generating plant being shut down at the hours of light load at the generating station, which is about two miles from the centre of distribution.

The equipment in the main dynamo room consists of three vertical triple-expansion Schichau engines, driving three two-phase Schuckert alternators of 300 kilowatts capacity each, direct-connected. The engines, which are of the marine type, run at 120 revolutions a minute, and, at an initial pressure of 150 pounds, develop 400 E.H.P. normally and 500 H.P. at a maximum, with jet condensation. The alternators have 28 poles, and the number of alternations is about 51 a second, this low rate being chosen because the only load is the sub-station equipment of motors. The magnet frame is of soft iron, in two parts, and is bolted to a cast-iron bedplate. The poles are cast in one piece with the magnet frame, and the pole-pieces, which are a little broader than the cores, are screwed to the latter. The armature frame consists of a solid wheel with six spokes, on the rim of which there is a bronze ring carrying the laminated armature core. This latter does not rest directly on the bronze ring, but on 16 projections from it, between which the air can circulate abundantly, so that the ventilation of the armature is provided for in the most effective manner. The diameter of the armature is 9ft. 10in., and the outer diameter of the magnet frame 12ft. 5¼in. The alternators, large as well as small, can be run in parallel with ease, which is done by means of a simple switch without the aid of artificial resistances.

At the acceptance tests, which were most carefully conducted by Prof. Kittler, of Brunswick, when the large alternators were run at the primary voltage of 1,780 to 1,790, the current in phase I. was 85·7 amperes, in phase II. 90·2 amperes. The energy consumed by the alternator was as follows:—

Loss in armature windings	8,550 watts
Loss in field winding	7,450 watts
Loss due to eddy currents, hysteresis and friction.	17,000 watts
Total	33,000 watts

Digitized by Google

The total energy delivered by the alternator was 284,000 watts; the efficiency of the machine was, therefore, slightly over 90 per cent.

The electrical plant at the primary station contains also a continuous-current dynamo, of 110 volts and 140 amperes capacity, for lighting the station and running the motors of the repair shop, and two non-synchronous two-phase motors, which serve to operate the pumps. The current for these motors is transformed from 1,800 to 110 volts. The condensing water is pumped to a cooling tower 36ft. high, whence the water falls through sieves to a tank, from which it is taken for condensing service. Besides the main plant there is also a temporary installation consisting of two 66-kilowatt two-phase machines.

The sub-station is located almost exactly in the centre of the district to be supplied. The dynamo room here contains two 120-kilowatt and two 240-kilowatt rotary transformers. The larger machines run at 220 revolutions per minute, at which speed the continuous-current armature gives 240 volts. The acceptance tests of the rotary transformers showed a commercial efficiency of 82 8 per cent. These machines are switched in in the following manner: Current from the accumulators is led to the continuous-current dynamo; the latter runs as a motor, and carries with it the alternating machine on the same shaft. When the proper speed of the alternating motor has been reached, and as soon as the latter is in step with the primary alternator, the motor is connected with the primary circuit, and the accumulators are disconnected from the direct-current machine, which is then connected in on the distributing mains as a dynamo, in the usual way.

Tudor accumulators are used, and the plant comprises four batteries of 148 cells each, connected in parallel. The whole accumulator plant has a capacity of 6,260 ampere-hours with a discharging current of 1,876 amperes, or 8,980 ampere-hours with a discharging current of 1,072 amperes, and can, therefore, supply 7,500 16 c.p. incandescent lamps for 3½ hours, or 4,288 lamps for 8⅓ hours. The batteries are set up in the four stories of the accumulator house. Each storey holds a complete battery of 148 cells. The four batteries are connected in parallel by vertical conductors passing through the four stories. The accumulator switching device is rather novel. The connections are so arranged that an upward movement of the sliding contact raises the potential and a reverse movement lowers it, which avoids confusion on the part of the attendant. By two complete revolutions of the regulating handle one accumulator cell is cut in or out. When the sliding contact rests on the battery contact bars in such a position that the dynamo current goes directly into the accumulators, or the accumulator current directly into the omnibus bars, if the handle is then given one complete turn, resistances, which can be varied to suit the current, are thrown into circuit. By this simple contrivance the gradations of potential between adjoining cells are halved, and the cutting in or out of cells is hardly perceptible at the lamps. The battery switches have two contacts, charging and discharging. By a combination reversing switch both contacts can be used for discharging, and it is then possible to divide the feeders into two groups, and to regulate the potential of each group independently. The distribution is done on the three-wire system; underground cables of the lead-covered, iron-armoured type are being employed, laid direct into the ground. The high-pressure feeders are concentric cables.

In order to eliminate the troubles due to unequal discharging of the batteries used on the two sides of the three-wire system, a compensating dynamo was recently put in, which, when necessary, completes the charge of that half of the battery which had discharged at the greater rate on the preceding day.

LONDON COUNTY COUNCIL.

LIGHTING OF THE VICTORIA EMBANKMENT AND THE WATERLOO AND WESTMINSTER BRIDGES.

At the weekly meeting of the London County Council, held at the County Hall, Spring-gardens, on Tuesday, Sir Arthur Arnold presiding, the report of the Highways Committee on the subject of lighting the Victoria Embankment and Waterloo and Westminster Bridges came up for discussion. The recommendation of the report (which has appeared in *The Electrician*) was as follows:—"That, subject to an estimate being submitted to the Council by the Finance Committee as required by the statute, the Highways Committee be authorised to take all the necessary measures for establishing, at a cost not exceeding £16,590, electric lighting for the Victoria Embankment and the Waterloo and Westminster Bridges (but exclusive of the Embankment Gardens), authorised by the Council's (General Powers) Act, 1893; and that for this purpose the Committee be authorised to obtain tenders and to enter into contracts on behalf of the Council."

Mr. J. Thornton said he would move as an amendment, "That the report be referred back, and the Highways Committee be instructed to obtain reports from the engineer and the chemist upon the question whether the lighting of the Victoria Embankment and the bridges could be improved by the substitution of incandescent burners for those at present in use." It was within his knowledge that the cost of incandescent lighting would be much cheaper. In the case of a private consumer it had come to his knowledge that the incandescent burner consumed one-third less gas than the ordinary burner, and if that was so they could get a much better light from the same cause. The question was brought forward as to whether the delicate nature of the burner was suitable for the purpose, but they had no information of that.

The Earl of Onslow, in seconding the amendment, said there were two classes of traffic using the Embankment. There was the vehicular traffic, which was at no time excessive, and which in the evening time was very slight. Then there were the pedestrians who used the Embankment for promenading. He was one who used it for that purpose, and he certainly would not welcome a brilliant electric light, because in his case a walk in the quiet by the silvery Thames was far better than the brilliant glamour of Piccadilly. He supported the proposition of Mr. Thornton, and would go a step further, and include in the amendment the third alternative which would be suggested—of ascertaining upon what terms a private company would supply electricity.

Lieut.-Col. Ford said that it was unfortunate that new members of the Council, before opposing the motion, did not take the trouble to investigate the past history of the question. He happened to know that the Committee had given an infinite amount of pains to the matter. There was a much more important aspect of the question than merely lighting the Embankment, for there was the lighting of the two bridges. He spoke for the thousands of working people who used those bridges, that they should be given every convenience. It was said the cost was excessive, but he saw that the cost of installing the electric light in one of their asylums was £21,000; and if they would spend that sum for lighting a single building, surely they would spend a smaller sum to light the principal thoroughfares of their city. The mover and supporters of the amendment seemed to think that the question of lighting with gas had not been considered by the Committee. It was considered very carefully in 1893, and the Committee came to the conclusion that the best way to deal with the question was to light the Embankment and bridges by electricity. In some of the smallest municipalities they used electricity for lighting the streets. Seeing that the Council got their Act in 1892 it was time they did something.

Mr. Jones said that, although two of the speakers had said the Embankment was sufficiently well lighted at the present time, he did not think that was the opinion of the people of London. Their arguments proved that the place was insufficiently lighted. He knew the incandescent light had been successful in many places. In a large business with which he was connected it answered admirably, but out of doors it was a question whether it would do. As far as Westminster and Waterloo Bridges were concerned, he thought it would not answer at all—the situation was too exposed, and the wind and so on would be too great. In Kensington it was found that the vibration caused by the traffic interfered with the delicacy of the burners. He had no objection to trying the experiment on the Embankment, because when the Parks and Open Spaces Committee had thinned the trees it would enable them to place the standards for the electric light with better advantage some time hence.

Col. Rotton expressed the opinion that the incandescent light was stronger than the electric light of the same power, and the consumption of gas was much reduced by the use of the burners. The trouble caused by the vibration of traffic had been got over. He thought there were sufficient reasons for referring the matter back, and trusted that course would be adopted, as it was much too late to adopt electric lighting for the coming winter.

Alderman Beachcroft said there was no doubt the streets of London were the worst lighted in the world, and the question raised was exceedingly pertinent. They wanted more information. It might be that the Committee had got information, but so far the report seemed of a barren character. He read that the incandescent burner had treble the lighting power of the ordinary burner, and only used half the gas. If so it would be advisable to have a report prepared as to gas being superseded by electricity. They were asked to spend £12,380 to establish the electric current, and seeing that there were four electric lighting companies in the surrounding neighbourhood who could supply them, it was only right the Council should have more information. The cost per year of the electric light was put at £2,768, which struck him as a very large increase upon the cost of gas. He trusted the Council would refer the report back for further information to justify them in coming to a conclusion.

Alderman Hubbard (Chairman of the Committee) said the question had been before the Council since 1892, and was brought before

Digitized by Google

them in consequence of the complaints of the insufficiency of the lighting of the Embankment. He was sorry Mr. Hoare did not on that occasion rise in his seat and tell them the light was sufficient. At any rate, it was on the assumption that the Embankment was insufficiently lighted that the Highways Committee brought up a recommendation to light it, the cost of the installation to be £10,000. The Council thought the bridges should be included, and it went further, and said also that the gardens should be lighted. The Committee brought forward an amended estimate of £15,000, and then the Council would not have the standards erected in the centre of the road, and sent the report back, and the Committee had to increase their estimate from £15,000 to £20,000. The question was raised whether the Council had power to undertake the work, but they went to Parliament and had got the power. Their engineer told them it would cost some £1,300 to place the incandescent light on the Embankment, and they would need new burners and standards. They were also told that the incandescent light cast great shadows down the road, and it would be a great mistake to place the light there if that was a fact. He believed the incandescent light had just been given up at St. Martin's Hall because it was found to be affected by the vibration. If they wanted to send it back for a year they had better at once discharge the order.

The amendment was then put and carried by 43 votes to 12.

Mr. E. WHITE then moved that the following words to be added to the amendment:—"That the Committee be instructed to report what is the cost of the present lighting, what would be the cost of incandescent gas lighting, and what would be the cost of electricity supplied by a company." He said that he was not opposed to the electric lighting of the Embankment, for if there was one place which should be lighted by electricity it was the Thames Embankment. What struck him, however, was the enormous cost at which it was proposed to instal the light. He found the capital expenditure was £16,590, which, divided amongst 83 lamps, amounted to £200 per lamp. That appeared an enormous sum, and he was informed by a gentleman well able to judge that the installation could be carried out for £10,000. Then, again, the annual cost was set down at nearly £3,000, which amounted to £33 per lamp. At Portsmouth the cost was only £18 per lamp. And, again, the wages appeared very large, averaging £9 per light. He thought they should know what the electric lighting companies in the neighbourhood would supply the light for. Then, again, he was told the installation station would be on the vacant land under Charing Cross bridge. It was said that was not so, and that would be another reason why the matter should be deferred so that they could find out where it would be, for they did not want to disfigure the Embankment. His motion was not hostile, for he was in favour of electric light, but he would like to know if it could not be carried out at less cost.

Major PROBYN seconded the motion, observing that an important point was to have the Embankment well lighted to assist navigation on the river. There was the Strand Electric Supply Corporation and the Metropolitan Electric Supply Company, and they could obtain information for them as to what they would supply the light for.

Mr. JONES said the electric lighting station would be on a piece of ground on the east side of the underground railway. The Committee had had the cost of one company before them, which was £30 per lamp, which amounted to £2,490 per annum, whilst the Council would have to provide standards, wire, &c., which made the difference in the estimate only £217. The estimate also was for a larger number of lights, and the hours allowed for lighting 260 less than the Committee's estimate.

The motion was then carried.

Mr. BENN further moved that the Committee be instructed to bring up an estimate of the cost of lighting the Victoria Embankment Gardens, and this was accepted without discussion.

CORRESPONDENCE.

SHIPBOARD GALVANOMETERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The want of a more satisfactory instrument than the ordinary ironclad Thomson marine galvanometer is so generally felt by those who "go down to the sea in ships" that any improvement will be cordially welcomed. In your impression of March 22nd I notice that the Sullivan "Universal" galvanometer is fully described, and in your later issues of July 5th and 12th the advantages of both this form and also of the more recent damping devices applied by Messrs. Weatherall and Clark to the ordinary Thomson *marine* galvanometer are set forth by their respective inventors. As no results of tests with the two instruments have, however, been published, the following comparison may be of interest to your readers. By the kindness of Messrs. Elliott Brothers I have had an opportunity of making a few experiments with a marine galvanometer fitted with the Weatherall and Clark damping device, and as these were made under precisely the same conditions as for similar tests when using the Sullivan "Universal" galvanometer they may be taken as indicating the comparative merits of the two instruments.

The Sullivan galvanometer experimented with was a new form, having a rather wider coil than those usually constructed, and a fixed internal soft-iron core. Resistance of coil = 600 units. This particular form of coil is said to secure more perfect throws for discharge tests and greater freedom from movement under excessive vibration, but to be less suitable for speaking purposes.

The other instrument experimented with was an ordinary Thomson marine galvanometer, fitted with the Weatherall and Clark arrangement for damping the mirror suspension so as to give it an almost dead-beat movement. Resistance of coil = 7,000 units. Distance from the mirror to the scale in both cases = 3ft. 5in.

Value of Readings under Prolonged Currents of Varied Strengths. Sullivan's Universal Galvanometer.

	ω.	
One cell (Leclanché) through	250,000 Sh. = ∞	= $126\frac{1}{2}$ divs.
	200,000 Sh. = ∞	= $158\frac{1}{2}$ divs.
	150,000 Sh. = ∞	= 211 divs.
	100,000 Sh. = ∞	= 317 divs.
	50,000* Sh. = ∞	= 634 divs.

These values show that the readings are in direct proportion to the current strength. No *creeping* was observed—the spot of light going straight to its position on the scale without any apparent oscillation, and remaining steadily at the same point when the current was kept on for five minutes. When the current was removed the light returned immediately to zero without the least deviation.

Weatherall and Clark's Galvanometer.

	ω.	Throw.	Fell back to	Creeping in ½ min. to	Light returning to
One cell through	250,000 Sh. = ∞	72	64	68	– 3†
	200,000 Sh. = ∞	91	81	84	– 3†
	150,000 Sh. = ∞	120	108	112	– 7†
	100,000 Sh. = ∞	175	157	168	– 12†
	50,000 Sh. = ∞	334	295	313	– 12†
	50,000 Sh. = ∞	335	295	330‡	– 37†

Second Test.

	ω.	Throw.	Fell back to	Creeping in ½ min. to	Light returning to
One cell through	50,000 Sh. = ∞	308	295	320	– 19†
Two cells through	50,000 Sh. = ∞	640	592	638	– 35‡

Since making the above comparisons I have been informed that experiments are being conducted with a view to reducing the *creeping*.

Sensibility of the two Galvanometers.

The above figures show that under a prolonged continuous current the Sullivan galvanometer is about twice as sensitive as the Thomson marine galvanometer with the Weatherall and Clark damping device; but even were the latter instrument equally sensitive and free from *creeping* and a varying zero, it still has a very great disadvantage, to which this kind of galvanometer is always subject—viz., that the zero is displaced as the ship's course is altered. From this frequent source of annoyance a galvanometer on the d'Arsonval principle is fortunately free. Moreover, when the silk fibres stretch or the ship changes her latitude considerably, the balance of the Weatherall and

* Zero taken was 315 divs. on the opposite side of the scale zero.

† These readings are only approximate, for, though the spot of light settled down at about these positions, it continued to return slowly to the scale zero. What with the deflection creeping up the scale and the light not returning to a definite zero, exact measurement was next to impossible, and readings during a prolonged insulation test would be very unsatisfactory.

‡ Prolonging the current for five minutes creeping increased the deflection from 295 to 330 divs.

Digitized by Google

Clark suspension will frequently have to be touched up. However carefully this is done it is always liable to strain the silk suspension. A slight slackening of the fibre in the ordinary Thomson marine would not prevent the slide from being useful for testing; but so narrow must necessarily be the limits in which the Weatherall and Clark suspension moves (in order to obtain the requisite dead-beat effect) that a good deal of trouble is likely to arise from this cause. The suspension shown to me at Messrs. Elliott Brothers' was very beautifully made and remarkable for its finish, but, speaking from a familiarity with marine suspensions extending over many years, it appears to me likely to give trouble on board ship when from any cause the fibre slackens slightly.

As a Speaking Instrument.

For speaking purposes both instruments are sufficiently *dead beat*, and signals are easily readable, whether working on short-circuit with a shunt of next to no resistance between the terminals or through 250,000 units with shunt infinity. In the case of the Weatherall and Clark instrument, however, there is the slight *throw back* after each signal, as pointed out when testing by direct deflection. This is noticeable both at a moderate and high speed of signalling, whereas the Sullivan galvanometer is absolutely free from any of these *back kicks*, and the signals are on that account rather more distinct.

Reading Discharges from a Condenser.

The Sullivan instrument gave the following results:—

Discharge from	$\frac{1}{3}$ mfd. condenser	with	1 cell Sh = ∞ =	20	divs. approx.
„	$\frac{1}{3}$ „	„	2 cells Sh = ∞ =	41	„ „
„	$\frac{1}{3}$ „	„	3 cells Sh = ∞ =	61½	„ „
„	$\frac{1}{3}$ „	„	4 cells Sh = ∞ =	82	„ „
„	$\frac{1}{3}$ „	„	5 cells Sh = ∞ =	103	„ „
„	$\frac{1}{2}$ „	„	5 cells Sh = ∞ =	162	„ „
„	$\frac{1}{3}+\frac{1}{2}$ „	„	5 cells Sh = ∞ =	266	„ „

The foregoing results show that the throws are practically in proportion to the capacity of the condenser and the E.M.F. of the battery used. In every case the spot of light returned to the scale zero. For the Weatherall and Clark galvanometer the following results were obtained :—

				Throw to left.	Displacement of zero.
Discharge from	$\frac{1}{3}$ mfd. condr.	with	1 cell Sh. = ∞ =	27 divs.	1 to right*
„	$\frac{1}{3}$ „	„	2 cells Sh. = ∞ =	53 divs.	10 „
„	$\frac{1}{3}$ „	„	3 cells Sh. = ∞ =	86 divs.	15 „
„	$\frac{1}{3}$ „	„	4 cells Sh. = ∞ =	112 divs.	21 „
„	$\frac{1}{3}$ „	„	5 cells Sh. = ∞ =	140 divs.	23 „
„	$\frac{1}{2}$ mfd. „	„	5 cells Sh. = ∞ =	211 divs.	35 „
„	$\frac{1}{3}+\frac{1}{2}$ mfd.† „	„	5 cells Sh. = ∞ =	349 divs.	58 „
„	$\frac{1}{3}+\frac{1}{2}$ mfd.‡ „	„	5 cells Sh. = ∞ =	332 divs.	46 „

In the above discharge tests it will be seen that the results are decidedly in favour of the Sullivan instrument. The weak point about the Weatherall and Clark instrument in this case is the failure of the spot immediately to return to the position of the scale from which it started, so that the true reading is always doubtful. Both instruments are rather rapid in their movements, and it is necessary sometimes to observe two or three throws in order to make quite sure of the correct reading.

Judging from the satisfactory results obtained with the Sullivan galvanometer, there is no question that it is very superior to the Weatherall and Clark instrument tested by me, and a very important improvement in every way on the ordinary Thomson marine galvanometer, and will therefore be welcomed by electricians for board-ship work.

The limited time at my disposal prevented me from trying the two instruments when inclined to one side, as when the ship is rolling. Under such conditions it is probable that a discharge to the lee side will exceed the discharge to the opposite side of the scale; for however well balanced, there must necessarily be a certain degree of sag owing to the weight of the suspension, which would increase the throw to the leeward side. For capacity or discharge tests in general a *null* method is on board ship, for many reasons, I think, preferable.—Yours, &c.,

J. Rymer-Jones.

* In all cases returning very slowly indeed to zero.
† Zero in this case was 100 divs. to the right of scale zero.
‡ Starting from the scale zero.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In my letter of July 2nd (see *The Electrician* of July 5th, p. 335), mentioning an "improved method of damping marine mirror galvanometers," I refrained from publishing a full description until I had made the improvement as perfect as possible. I now send you particulars of the system with diagrams.

The damper *d*, Fig. 1, is of sheet aluminium of length and width necessary to obtain the degree of air damping required. A hollow, *b*, to hold the mirror is stamped in the centre, and the magnet *m* is riveted at the back of it. Small claws *c* are cut out on the edge of the hollow *b*, and these are used to clamp the mirror in position. The small spaces left in the damper *d* by the turning over of these claws are utilised for balancing purposes by inserting suitable weights, thus dispensing with shellac, which was formerly employed for securing mirror, magnet and weights. The damper *d* is divided down the centre of its length by a slot $\frac{1}{16}$th of an inch wide to a

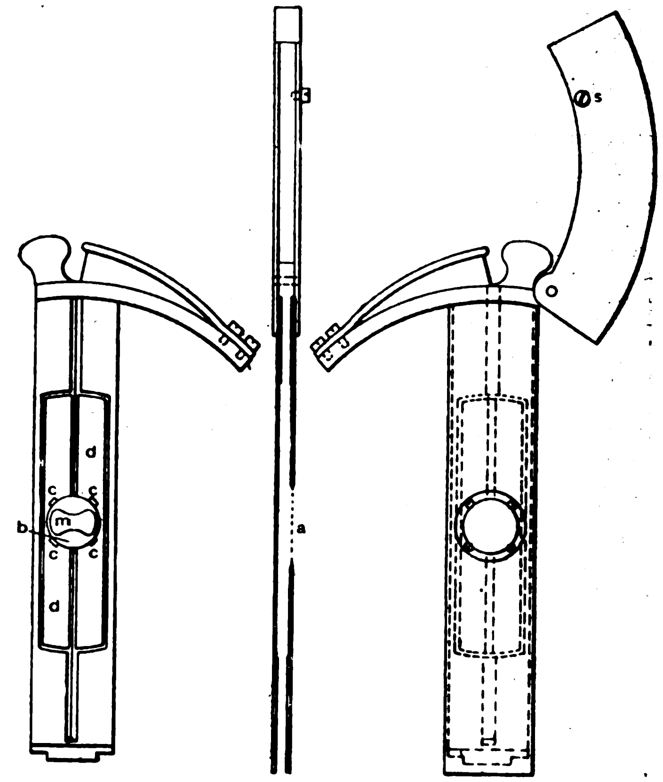

Fig. 1.—Slide. Back view. Fig. 3.—Jacket. Section. Fig. 2.—Jacket. Front view slide inside.

position slightly inside the rim of the hollow *b*, and two lugs about $\frac{1}{16}$th of an inch long are left, which project above and below the hollow, each pierced on its outside rim with a pinhole to receive the fibre for suspending. The magnet is very light and, as shown, of dumb-bell form. The total weight of the system (damper, mirror, magnet and the necessary weights for balancing) is about three grains, which is very much the same as that of the old style of suspension.

The jacket, of which a front view is given in Fig. 2 and a section in Fig. 3, completely envelops the slide and protects it. The cover, shown open for the removal of the slide from the jacket, is, when closed, secured by a screw, *s*; thus the whole arrangement is rendered air-tight and portable.

The aperture *a* in front of the mirror is filled in with microscopic glass or any transparent substance.—Yours, &c.,

East Greenwich, July 16, 1895. Thomas Clark.

THE WIMSHURST INFLUENCE MACHINE.

TO THE EDITOR OF THE ELECTRICIAN.

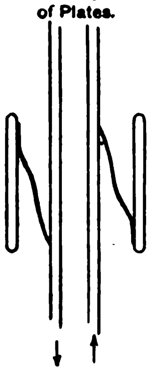
Sir: Referring to your reprint of Father Schaffers' article in last week's issue, I must confess I fail to see exactly in what respect he has succeeded in improving the Wimshurst machine.

Digitized by Google

The final stage of development he arrives at has certainly very little in it that is novel, being simply a somewhat distorted Wimshurst. The two collecting combs in connection with each electrode certainly are set farther apart than others have previously set them ; but this is a very doubtful improvement, as it means increased facility for leakage across to the diametral conductors, and consequently a lower maximum potential difference between the knobs. Also the contact brushes are on the collecting combs instead of on the diametral conductors. I do not see that this is a matter of vital importance so long as one of the two is not provided with them.

A word also with regard to the method of comparison. It should be borne in mind that the Wimshurst machine is essentially a high-tension machine—that is to say, it works at its best with the knobs far apart and small capacity in connection with them. Father Schaffers does not give dimensions of the machine, or say what length of spark the Lane bottle was adjusted to give (and for anything approaching accuracy this must necessarily be short), but it appears that the method of testing keeps the machine working at a comparatively low tension. This is unfair. For whatever purpose the machine is to be used, it can always be arranged to keep the electrodes at a high difference of potentials, even when charging Leyden jars of large capacity, by simply introducing a spark gap into the charging circuit.

With regard to the change of sign of the charge on the plates after passing the collecting combs; this may be so whilst the machine is working at a low tension, but when working at its normal high tension, so far from changing sign, a strong charge of the same sign is undoubtedly left on the plates and greatly assists the action. I have described a modified Wimshurst machine in the pages of a contemporary (*Electrical Review*, Vol. XXXI., p. 457) some three years ago, having, among other improvements, collectors made of flaps of stiff oiled silk or paper edged with conducting material, which allowed contact with the rotating plates both in the collectors and diametral conductors, the flaps being attracted up to the plates automatically by the action of the machine, restoring themselves directly the tension becomes dangerously low. These flaps also collected from the plates on opposite sides, at points which were designedly considerably in advance of the horizontal diameter in the direction of rotation, thus :—



With reference to the preceding article in the same issue, I cannot see from it that Prof. Holtz has made good his claim of priority of invention of the Wimshurst machine, and certainly the form of machine usually described as Holtz No. 2 is far behind machines of the Wimshurst type from all points of view.

In conclusion, I must say that both the articles referred to are by no means easy reading, not only on account of the expressions used, but also through being complicated by the idea of + and − charges, and their mutual and counter inductions. Unfortunately the whole science of electrostatics is based on such old-fashioned notions that it is only by the free use of these symbols that one can make oneself understood.—Yours, &c., J. E. TAYLOR.

Holloway, N., July 22, 1895.

LEGAL INTELLIGENCE.

British Insulated Wire Company v. the Prescot Urban District Council.

On Monday last Justices Grantham and Wright had before them an application to mark this case as urgent, and to put it into the list for Monday next.

Mr. SANDERSON stated that the question was whether an agreement made between the plaintiffs and the defendants was invalid by reason of a subsection of the Public Health Act. The urgency lay in the fact that unless the matter was determined before the Long Vacation the Local Board would be unable to enter into another contract for their winter lighting, and the winter lighting would thus be impossible. The matter was tried at the Liverpool Assizes, and Mr. Justice Day said that it ought to be tried as a special case, and he therefore asked that the case be put into the list for Monday next.

The application was granted.

National Electric Engineering Company (Limited) v. Arnold.

Recently, at the Brentwood County Court, the National Electric Engineering Company (Limited) brought an action against W. Arnold, a tailor and outfitter, of Brentwood, to recover possession of a dynamo and packing case, valued at £20. 16s., and the plaintiffs further claimed £5 damages for the detention of same.

Mr. A. C. COCKBURN (a Managing Director of the Company) deposed that a dynamo was sent to Mr. Arnold's premises by the direction of a Mr. Miller. He subsequently saw Mr. Arnold, and asked him to return the machine, who said it had been supplied to him by Miller, and that he intended to keep it in order to pay for the completion of Miller's work. Subsequently the defendant was served with a formal notice demanding the return of the dynamo.

His HONOUR (Judge Paterson) held that the defendant had to prove that Mr. Miller was the owner of the dynamo, and, in answer to his Honour,

Mr. COCKBURN said his Company did not sell the dynamo to Mr. Miller.

Mr. WALKER (plaintiffs' solicitor) said the dynamo was not sold to anyone, but it was supplied on certain specific terms.

In cross-examination, the WITNESS admitted that Miller had been asked to pay for the dynamo or return it. The dynamo was loaned to Miller on the condition that it should be kept if satisfactory.

His HONOUR said that as the dynamo had not been returned it would be taken that it was satisfactory, and that if it had been illegally obtained from Miller he (Miller) must bring an action to recover it.

HENRY MILLER said he entered into negotiations with the Company regarding the dynamo, and he came to an arrangement with the defendant by which the dynamo, if satisfactory, would be left on Mr. Arnold's premises and sold to him, but if not it would be returned by witness. As it did not arrive in time he got another dynamo, and when the dynamo in dispute arrived Mr. Arnold asked him to see if it worked better than the other one. He did so, but as it did not he took it out again, and when he went to take it away the defendant would not release it.

His HONOUR said that to his mind there was no case whatever, and non-suited the plaintiffs with costs.

Dawson v. Foster.

The plaintiffs in this case, which was heard on Friday in the Bloomsbury County Court (London, W.C.), Roger Dawson (Limited), electrical engineers, sought to recover payment of an account in respect of the installation of the electric light. The evidence went to show that the order for the work was given by the defendant's wife, and he objected to pay the plaintiff's claim on the ground that he had strictly forbidden his wife to pledge his credit. In giving judgment his Honour said it was a hardship upon tradesmen after they had done the work to be met with a defence like this, but at the same time they should be careful to find out who they were to look to for payment before carrying out orders which were given by women. The defence was fatal to the plaintiffs' claim, and judgment must be for the defendant, but he certainly should not allow the defendant's costs.

Barclay v. The New Zealand Electrical Syndicate (Limited).

Mr. Justice North, in the Chancery Division, on Saturday last, made an order continuing the receivership, which was originally to have expired in October next. There had, since the Receiver and Manager was appointed in March last, been a further default in payment of interest and principal upon an issue of debentures of £30,000, which were held by the plaintiff. The Company was originally formed to light the City of Wellington, New Zealand, by electricity, and was practically a branch of the Gulcher Company. Reference is made to the affairs of the New Zealand Electrical Syndicate in the report of Mr. Fitch Kemp, the liquidator of the Gulcher Company, in another part of this issue.

Martin v. The New British Electrical Installation Contractors (Limited).

Mr. Justice Kekewich has appointed a Receiver and Manager in this failure. The application was not resisted by the Company. Mr. Lester, of Worcester, is the Receiver and Manager, his Lordship refusing to give any directions as to the management.

Digitized by Google

Clements v. Edwards.

This action, which came before Mr. Justice Wright (without a jury) in the Queen's Bench Division last Saturday, was brought by Mr. Isaac Clements, of Birmingham, to recover £71. 13s. 9d., balance of an account for electric light fittings supplied during the years 1894 and 1895 to the defendant, a builder and contractor, carrying on business in London. The defendant pleaded that when the writ was issued in April the money was not due for some of the goods, and the plaintiff admitted that the goods were supplied on the understanding that they should be paid for at the end of the following month, when a discount of 5 per cent. would be allowed, and some of the goods were supplied to the plaintiff in March.—His Lordship, having gone through the account, reduced the plaintiff's claim to £45. 13s. 9d., for which he gave judgment, with costs.

Scarlett v. Frank and Co. (Limited).

The plaintiff in this action held nearly all the debentures issued by the defendant Company, a firm of electrical engineers and contractors, and Mr. Justice North appointed a Receiver and Manager, with the usual reference to Chambers.

Wood v. Woodhouse and Rawson United (Limited).

A summons was to have been heard before Mr. Justice Vaughan Williams on Wednesday last for leave to institute proceedings in this action, but the case was not reached. It is to come on again next week.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

SPECIAL NOTICE.—The 1895 (thirteenth) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. In addition to the old well-known features of the book, which are brought up to date, a quantity of new and useful matter has been added, rendering the book more than ever indispensable to the Electrical, Engineering, and Allied Trades. Price, 7s. 6d., post free 8s. 3d., abroad 9s.

The following New Books and Editions of "The Electrician" Series *can be obtained of the Booksellers or direct from the Publishing Offices:—*

Laboratory Notes and Forms.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett (*now ready*). Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"Electric Lamps and Electric Lighting," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

A Large-Sheet Table, giving full particulars of the Electricity Supply Stations throughout the Kingdom, can now be supplied mounted on stout board, with cord for hanging. Price: Varnished, 3s. 6d.; Unvarnished, 3s.—each post free. A Map showing positions of Supply Stations throughout the country is mounted on the back of the Table, and a Coloured Map of Metropolitan Electric Lighting Areas and a large sheet of Electricity Supply Statistics are also mounted on some copies, the price of which complete, post free, is 5s.

A Sheet Table showing Total Capital Outlay and Receipts and Expenditure for the year 1894 of the Statutory Electric Supply Undertakings of the Metropolis is now ready, printed on thick paper, price 6d. each.

"The Work of Hertz."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"Electrical Engineering Formulæ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"Drum Armatures and Commutators."—By Mr. F. Marten Weymouth, is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"The Incandescent Lamp and its Manufacture."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application

"Practical Notes for Electrical Students."—By Messrs. A. E. Kennelly and H. D. Wilkinson, price 6s. 6d., post free.

"Electric Motive Power."—A new work, by Mr. Albion T. Snell, with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

Tenders Invited.—**The Corporation of Brighton require tenders for the supply and erection, at their electricity works, North-road, of evaporative brass tube surface condensers, electrically-driven air pumps, and exhaust and condenser pipings. Tenders must be in before 10 o'clock August 10th.**

——— Tenders are invited by the Vestry of Hammersmith, London, W., for complete schemes for public and private lighting, and for the supply of motor power in the compulsory area of the Vestry's Provisional Order. Some particulars are given in our advertisement columns, and all further information can be obtained of Mr. H. Mair, Surveyor to the Vestry. Tenders have to be sent in by 6:30 p.m. of Wednesday, September 4th.

——— The Salford School Board invite tenders for the installation of the electric light in their new offices in Chapel-street, Salford. Plans and specifications may be obtained from Mr. S. V. Clirehugh, Temple Chambers, Brazenose-street, Manchester. Tenders, addressed to the Chairman of the Board, must be in by 12 o'clock on Wednesday, July 31st. Additional particulars may be obtained from our advertisement columns.

——— The Electric Lighting Committee of the Wakefield Corporation invite tenders for the supply and erection of (*a*) boiler and fittings, mechanical stokers and engine, economiser, feed pump, injector, &c.; (*b*) steam alternators, condensers, oil filter, fittings, &c., steam, exhaust, feed, blow-off and sundry pipes, valves and water tank, &c.; (*c*) main switchboard and instruments; (*d*) cables, junction boxes, culverts, and trenching, &c.; (*e*) transformers and switchboard, &c.; (*f*) arc lamps and posts; (*g*) meters, and (*h*) overhead crane. Plans and specifications may be obtained from Mr. Robert Hammond, the consulting engineer, Ormond House, Great Trinity-lane, London, E.C., after Friday next, August 2nd, and tenders, addressed to the Town Clerk (Mr. Chas. Jas. Hudson), Town Hall, Wakefield, must be in by 2 p.m. on Saturday, August 24th. Some further particulars appear in our advertisement columns.

——— The Crown Agents for the Colonies require tenders, to be delivered by 11 a.m. on Thursday next, for the supply of materials in connection with the installation of the electric light in the Civil and War Department buildings at Malta. The materials required comprise cables and wires, tools, &c., fittings, fixtures, &c., and sundries.

——— Tenders are being invited for the electric lighting of the Mechanics' Hall and Saloon, Bradford. Tenders to Mr. T. C. Hope, architect, 27, Kirkgate, Bradford, by July 30th.

——— Wednesday next, the 31st inst., is the last date for sending in tenders for the supply and erection of plant for the electric lighting of the Schaerbeck-Nord Railway Station, Brussels. Tenders to the Ministère des Chemins de Fer, Postes et Télégraphes, Brussels.

——— The municipal authorities of the Deva, Guipuzcoa province, Spain, invite tenders for the electric lighting of the public streets under a ten years concession. Tenders, by the 28th inst., to the Secretaria del Ayuntamiento de Deva, Guipuscoa, Spain.

——— The French Post and Telegraph Authorities are inviting tenders until August 1st for the supply, in one lot of 50 kilometres of telephone cable (double conductor), and for the supply of a quantity of paper-insulated electric cables in five lots. Tenders are also being invited until the 30th inst., by the same department, for the supply and laying of a submarine telegraph cable between Djibonti and Obok. Tenders in each case are to be addressed to the Direction Générale des Postes et des Télégraphes, 103, Rue de Grenelle, Paris.

——— The Shoreditch Vestry invite tenders for the erection of a chimney shaft at their electricity works. Tenders must be sent in to the Vestry Clerk (Dr. H. Mansfield Robinson), Town Hall, Old-street, Shoreditch, E.C., by Monday next.

——— The Secretary of State for Foreign Affairs has received a copy and translation of a notice issued by the Municipality of Vienna, inviting tenders for plans, construction and working of a network of electric railways in and round that city. Tenders must be in by November 14th next. The notice may be seen at the Commercial Department of the Foreign Office, Downing-street, S.W., between the hours of 11 and 6.

Tenders Accepted.—The Electric Light Committee of the Bedford Corporation have accepted the following tenders for the supply and erection of water-tube boilers, engines, and alternators:—

Two water-tube boilers.—	
Babcock and Wilcock (Limited)	£960
Two engines.—	
W. H. Allen, Son and Co.	906
Two alternators.—	
Siemens, Bros. and Co. (Limited)	1,530
Three transformers.—	
Johnson and Phillips	225

Digitized by Google

TENDERS ACCEPTED.—The Metropolitan Asylums Board have accepted the tender of Messrs. Thorpe and Waring for wiring for the electric light the five new wards and other buildings now being erected at the North-Western Hospital, Haverstock Hill, London, N.W., for the sum of £554. The following is a complete list of the tenders sent in :—

Thorpe and Waring, Theobald's-road (accepted) £554 0 0

Vaughan and Brown. .	£1,557	0	0	J. C. Howell (Limited) ..	£981	16	4
V. G. Middleton	1,440	0	0	Julius Sax and Co.	944	8	9
Hayward Tyler and Co.	1,340	0	0	Paterson and Cooper ...	895	0	0
Roger Dawson (Limited)	1,140	0	0	Benham and Sons.........	870	0	0
Tayler-Smith Electric Company..............	1,121	0	0	Fowler, Lancaster and Co., Birmingham	859	15	0
Sharp and Kent.........	1,098	0	0	Waring and Sons	688	15	0
Miller and Woods	1,070	0	0	T. Matthews..............	650	0	0
London and Lancashire Electric & General Engineering Company	1,050	0	0	Electrical and General Engineering Company.	649	0	0

All other firms of London.

——— The Brighton Town Council have accepted the tender of Messrs. John Fraser and Son, of Millwall, London, E., for the supply and erection of steam and feed piping, feed pumps, economiser, water purifier, tanks, coal elevator, and sundries required at the electricity generating station for £3,220. This was the only tender received.

APPOINTMENT.—The Shoreditch Vestry have appointed Mr. W. C. Gardner clerk of the electricity works at Pitfield-street, at a salary of three guineas per week.

APPOINTMENTS VACANT.—The Electricity Department of the Vestry of St. Mary, Islington, London, N., require an electrician to take charge of the electric mains, house connections, transformers, &c., at a salary of £2. 10s. per week; also a jointer for vulcanised rubber work. Further particulars will be found in our advertisement columns, and applications for both appointments have to be in by Wednesday, the 31st inst.

——— The Governing Body of the Northampton Institute, Clerkenwell, E.C., are prepared to receive applications for the appointment of a principal. The salary attached to the office has been fixed at £600 per annum, and the duties will commence on January 1st next. Applications must be sent in, before 10 a.m. on September 4th, to the Clerk (*pro tem.*), Mr. J. J. Lambert, 8, Dowgate-hill, Cannon-street, London, E.C.

——— The University College of South Wales and Monmouthshire require an assistant lecturer and demonstrator in engineering. Applications should be sent to the Registrar and Secretary (Mr. J. A. Jenkins, B.A.) by August 31st next. Further information is given in our advertisement columns.

CHANGE OF ADDRESS.—Mr. R. Falshaw, electrical engineer, has removed to Albert Chambers, Harrogate.

LEGAL NOTICE.—Our advertisement columns contain a notice relating to proposed alterations in the Memorandum of Association of the Consolidated Telephone Construction and Maintenance Company (Limited), by which it is proposed that the scope of the Company's operations shall be extended. A petition to this effect, presented to the High Court of Justice on the 12th inst., is directed to be heard before Mr. Justice Chitty on the 10th prox., and creditors and shareholders are notified that any opposition to this course must be made at the time of hearing. Copies of the petition can be obtained by any creditor or shareholder of the Company on payment of the usual charges. Messrs. Linklater, Hackwood, Addison and Brown, 2, Bond-court, Walbrook, London, E.C., are solicitors in this matter.

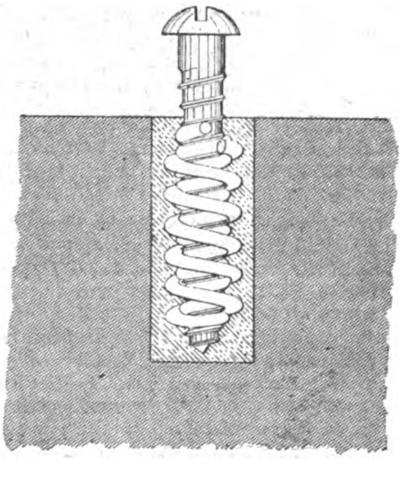
PURCHASE.—The Nalder and Harrison Construction Syndicate (Limited) have purchased the stock, plant and goodwill of the old-established engineering business hitherto carried on by Messrs. John Brown and Co., at the Perseverance Iron Works, Bow, London, E.

AGENCY.—Messrs. Francis and Spilsbury have been appointed agents for the sale of Messrs. Connolly Brothers' manufactures in the South, East, and West of England, not including London.

BANKRUPTCY.—In the failure of Joseph Torr Todman, a general meeting of creditors was held on Tuesday to consider a scheme of arrangement. The debtor has lodged a proposal to pay a composition of 7s. 6d. in the £ by instalments extending over eight months, and the terms of the proposal were deemed by the creditors to present an advantage over bankruptcy proceedings, subject to the security offered for the payment of the deferred instalments being fully approved. The Court is to be asked to sanction the scheme.

LIQUIDATIONS.—At a meeting on the 4th inst. it was resolved that the Printing Telegraph and Construction Company of the Agence Havas (Limited) be wound up, and Mr. W. H. King, 13 and 14, Basinghall-street, London, E.C., was appointed liquidator.

THE BOEDDINGHAUS DOUBLE-SPIRALLED PLUG.—We have received from Mr. Julius Boeddinghaus, of Dusseldorf, Germany, a sample "double-spiralled" plug. This consists of an inner tightly-twisted spiral, which serves as a female screw, and an outer loosely coiled spiral. The use of this device is recommended wherever an object has to be secured to a wall without causing much damage. A small



hole is cut in the wall, and a "double-spiralled" plug dropped in and secured in its place by means of plaster of Paris or cement, the switch base or rosette being then secured to the wall by means of screws driven into the plugs beneath. This system would seem to possess many advantages, especially where large screws have to be driven into a plaster wall.

ACTON.—The District Council have determined to oppose the application of the Capital and Counties Electricity Supply Company for a Provisional Order for lighting this district by electricity.

A NEW GOLD RECOVERY PROCESS.—The usual treatment of the tailings from gold mining crushings by what is known as the cyanide process is associated with electrolysis, but a recent discovery by Messrs. Sulman and Teed is stated to enable the ore taken from gold mines, whether largely or only lightly mixed with the baser metals, to be treated without the use of the electrolysis method. A company called the Gold Ore Treatment Company of Western Australia (Limited) has been formed to work the new process in Australia with a capital of £150,000 in £1 shares.

BIRMINGHAM.—The new Birmingham Meat Market and slaughter houses, the foundation stone of which was laid on Wednesday last by Mr. Ebenezer Parkes, M.P., will be lighted electrically.

BRADFORD.—The Electric Lighting Committee of the Corporation held a meeting on Monday to consider the question of the appointment of an electrical engineer in the place of Mr. S. Baynes, who has received a similar appointment from the St. Pancras Vestry. Fifty-six applications were received in answer to the advertisement recently issued by the Committee, and out of this number three were selected from whom a final choice is to be made. The salary attached to the office is £300.

DERBY.—Col. W. M. Ducat held a Local Government Board inquiry at Derby on Wednesday into the application of the Town Council to borrow, amongst other sums, £13,000 for electric lighting extensions. The Town Clerk (Mr. H. F. Gadsby), who explained the nature of the various loans, said the Local Government Board had already sanctioned the borrowing of £35,000, and the additional £13,000 now asked for was to make up the actual expenditure over and above the sum previously granted. This extra expenditure was caused by alterations to the adjoining premises and the putting down of additional boilers.

EDINBURGH.—The Town Council have approved the recommendation of the Cleaning and Lighting Committee (referred to in our last issue) that George-street and the streets leading thereto from Princes-street, along with St. Andrew-street, St. Andrew-square, Charlotte-square and Hope-street, should be lighted electrically.

EMBEZZLEMENT.—At the Bow-street (London) Police Court, on Monday, Wm. D. Boddy, a cashier in the employ of the Charing Cross and Strand Electricity Supply Corporation, pleaded guilty to embezzling £26. 19s. 3d., which had been handed to him on behalf of his employers. The prisoner admitted receiving other sums for which he had not accounted. Four months' hard labour.

FACTORY LIGHTING.—Messrs. Nicholson, Sons and Daniels have given instructions for the installation of an electric lighting and motive-power plant in their extensive factory and tan yards at Bethnal Green-road, London, E. The plant will comprise two

Digitized by Google

30 H.P. steam engines, a 160 H.P. water-tube boiler, a 250 light dynamo, motors, &c. The work has been entrusted to Messrs. Lee and Warren, who have executed similar contracts for Messrs. Lymington, of Market Harborough, and Messrs. Snook and Co., of Nottingham.

FULHAM (LONDON, S.W.).—The Vestry, at their last meeting, discussed the report recently presented by the Electric Lighting Committee, and referred to in our last issue, on the electric lighting of the parish. Mr. Cranfield moved the adoption of the report, but Mr. Thelwall thought that as only four members were present at the Committee some members hardly understood the scope of the scheme, and what a large matter it was. He moved that the Clerk obtain information from parishes where the electric light had been adopted, and, after some remarks from Mr. Sayer, it was agreed to refer the report back to the Committee for further consideration.

GLASGOW.—The Gas and Electric Light Committee of the Corporation have presented their financial statement for the past year. The gross revenue of the gas department was £629,362. 6s. 5d., and the gross expenditure £557,428. 15s. 5d., leaving a gross profit of £71,933. 11s. It was also decided to reduce the price of gas from 2s. 6d. to 2s. 4d. per 1,000 cubic ft. The gross revenue of the electric lighting department was £21,196. 11s. 4d., and the gross expenditure (including depreciation) £17,138. 18s. 9d. A payment of £5,000 on loans and sinking fund account leaves a deficiency of about £1,000, which was transferred to the gas account. It was agreed that the price of current should remain at 6d. per unit. The Committee anticipate that next year will be more prosperous, as they are now supplying current to 208 additional consumers.

HALIFAX.—As announced in our last issue, Major F. H. Tulloch held a Local Government Board inquiry on Friday last into the application of the Town Council to borrow £10,000 for electric lighting purposes. The Town Clerk (Mr. K. Walton) stated that the Council originally obtained permission to borrow £30,000. They had, however, found that they would require an additional £4,947 to complete their scheme, and £5,000 for extensions. They had expended £34,947, whereas the original estimate was only £26,100. The Corporation had intended to use some land that belonged to them for the purpose of erecting a generating station, but after further consideration it was decided that a more convenient site should be obtained, and this was done at a greater cost than the estimates provided for. The Committee had now decided to extend their mains to Skircoat, the chief residential part of the borough. There was no opposition to the proposed loan.

HAMPSTEAD (LONDON, N.W.).—At the last meeting of the Vestry the report of the Lighting Committee, recommending further electric lighting extensions at an estimated cost of about £3,182, was adopted. These extensions include Alexandra-road (£842), Avenue-road (£755), Belsize Park-gardens (remainder) (£201), Fairfax-road (£275), Finchley-road (£217), Hampstead Hill-gardens (£170), Heath-street (remainder) and North End (£571), and Kidderpore-avenue (£151).

HARROGATE.—Mr. George Wilkinson, M.I.E.E., has been appointed to advise the Corporation of Harrogate on the lighting of the New Montpellier Baths, which are being erected at a cost of £75,000. The current will be taken from the Corporation supply, Mr. Wilkinson acting as consulting engineer in this matter also.

HUDDERSFIELD.—At the last meeting of the Town Council the report of the Electric Lighting Committee, recommending certain extensions of the electric lighting mains, &c., at an estimated cost of £130, was approved.

IPSWICH.—Mr. E. A. Paris attended the last meeting of the Paving and Lighting Committee of the Town Council on behalf of the Brush Provincial Company for the purpose of ascertaining their views as to a proposed application by that Company for a Provisional Electric Lighting Order for Ipswich. After some discussion the Committee directed Mr. Paris to lay his application formally before the Town Clerk.

ISLINGTON (LONDON, N.).—The Vestry have decided to present a petition to His Royal Highness the Prince of Wales asking him to perform the ceremony of opening the electric supply station in November next. Islingtonians are very proud of their electric lighting scheme, the result of which, they claim, will be the finest installation in England. The chimney stack was completed last week. The shaft is 182ft. in height from the floor level, and its internal diameter is 24ft. at the bottom and 12ft. at the summit. Half-a-million bricks have been used in constructing the chimney, which is of sufficient size to provide for 16 boilers. Nearly 50 miles of cable have been laid in the compulsory area.

LIMERICK.—A special meeting of the Town Council was recently called for the purpose of formally adopting an electric lighting scheme for the town, but as a quorum could not be formed the consideration of the matter was postponed. The gasworks are under the control of the Corporation, and the members have been notified by the Board of Trade that if they do not adopt an electric lighting scheme the Board will give the necessary permission to a company seeking to have the Provisional Order, which the Corporation some time ago obtained, enforced in Limerick.

LOANS TO LOCAL AUTHORITIES.—The remarkable success which has attended the London County Council in its recent issue of Two and a-Half per Cent. Metropolitan Consolidated Stock brings the question of the rate of interest charged by the Council to the London vestries for loans for electric lighting, drainage and other important works prominently forward for discussion. The issue was for £1,000,000, and the applications reached no less than £3,232,800, at prices ranging from £101 the minimum, to £103. 5s. Nearly 70 per cent. of the loan will be placed at £102. 2s. 6d., and the average was £102. 7s. 5d. As the Council have fixed 3½ per cent. as the basis upon which loans shall be granted to local authorities for amounts under £5,000 and 3¼ per cent. for loans above that amount, the whole question must immediately come up for reconsideration. It is clearly evident that the London vestries would experience no difficulty in obtaining loans to any amount on the security of the rates at 2¾ per cent. and small amounts at 3 per cent. At the last meeting of the Council the Finance Committee took this subject into consideration, and they recommend that the rate of interest to local authorities on loans under £10,000 should be 3 per cent. and 2⅞ on sums above that amount. The London School Board have resolved to apply to Parliament for power to issue a Two and a-Half per Cent. Stocks, and the Finance Committee of the County Council are of opinion that it is inexpedient that there should be two Metropolitan Stocks, one consolidated and the other not consolidated, and recommend that the School Board should make its issue part of the Council's Metropolitan Consolidated Stock.

NEW ADMIRALTY BUILDING.—This handsome range of offices in Whitehall, London, S.W., is now nearly completed, and is expected to be out of the architect's hands in a few weeks. The whole of the building is to be lighted by electricity, and to have very complete outfit of telephones and electric bells.

NEW CRUISERS.—On Wednesday, the first-class protected cruiser "Powerful" was successfully launched at Barrow-in-Furness from the yard of the Naval Construction and Armaments Company. This is one of the latest type of warships, and an important feature is the substitution of electrical for mechanical motors for working the heavy guns, an alteration which it is expected will greatly increase the facilities for repairs while in action.

NORTHWICH.—At the last meeting of the District Council a letter was read from Mr. W. M. Beckett, of Manchester, informing the Council that he had prepared a scheme for supplying electric current to Northwich for lighting and power purposes, the scheme to be carried out either by the Council or by a private company. The letter was referred to the Lighting Committee.

REVISED ELECTRIC SUPPLY SCALE.—The St. James's and Pall Mall Electric Light Company (Limited), of Carnaby-street, Golden-square, London, W., have recently revised the scale of discounts and rebates under which electric current is supplied by the Company. The price per unit is 6d., or a minimum charge of 10s. per quarter. The following scale of rebates commences Lady Day, 1895:—

Units per annum.	Rebate per cent.	Approximate equivalent in pence per unit.
Under 3,000	—	6d
Over 3,000	1	
„ 4,000	2	
„ 5,100	3	
„ 6,300	4	5¾d.
„ 7,700	5	
„ 9,300	6	
„ 11,200	7	
„ 13,400	8	5½d.
„ 15,800	9	
„ 18,500	10	
„ 21,700	11	
„ 25,400	12	5¼d.
„ 30,000	13	
„ 36,200	14	
„ 45,000	15	
„ 60,000	16	5d.

Electric current for motive power, heating and cooking purposes is supplied at 4d. per unit.

ROTHERHITHE (LONDON, S.E.).—At the last meeting of the Rotherhithe Vestry a letter was read from the Capital and Counties Electricity Supply Company intimating their intention of applying for an electric lighting Provisional Order. It was decided to offer no opposition to the application.

SALFORD.—The Corporation Electricity Works are now practically completed and thoroughly equipped. Although the number of applications for current is smaller than was at first anticipated, it is thought probable that a greater demand will be made as the days become shorter. The charge for current will be 7d. per unit.

SHANGHAI TRAMWAYS.—A recent issue of the *North China Herald* contains the correspondence which has passed between Mr. L. S. J. Hunt and the Municipal Council of Shanghai on the subject of the concession for the proposed electric tramways. The final decision of the Council is that the matter be submitted to the ratepayers for confirmation or rejection. Mr. Hunt acknowledges the receipt of this notification, and reviews the questions raised by the Council's engineer as to the terms upon which the concession for the line is to be granted. The engineer's report is considered by Mr. Hunt to be favourable to the introduction of electric tramways into Shanghai, and with regard to a criticism as to the unsightly appearance of the overhead system Mr. Hunt points out that many of the objections that were raised in the early part of 1894 have been overcome by recent improvements. On the financial aspect of the question Mr. Hunt takes exception to the proposal that the concession should be for 21 years on condition that the Municipality should be able to purchase the property after that period, "on a basis which does not take into account the earning capacity." Mr. Hunt is of opinion that the clauses introduced in England for the acquisition of the tramways by local authorities have done more to obstruct tramway enterprise than to benefit the public. He thinks that if tramways are objectionable they should be forbidden, and if advantageous sufficiently good terms should be made to enable builders to reap a fair reward for their outlay. As to the tax which is claimed by the Municipality, Mr. Hunt agrees that some such tax should be paid, but if the requirements suggested by the municipal engineer are viewed by those working with Mr. Hunt as he views them, it would be better to withdraw from the field rather than attempt to carry such a burden. Mr. Hunt expresses his willingness to register the Company to work the tramways in Hong Kong, thus placing it under the jurisdiction of the English Courts.

SIEMENS AND HALSKE ELECTRIC COMPANY (OF AMERICA).—After the destructive fire which took place at this Company's works last year negotiations were immediately entered into for the purchase of the Grant Locomotive Works, and this purchase has now been completed. The ground owned by the Company is about 80 acres in extent, 30 of which are covered by buildings constructed and equipped for the production of heavy machinery. The works are situated in the town of Cicero, west of Chicago, close to the track of the Wisconsin Central and Chicago and Northern Pacific Railroads.

SOUTH STAFFORDSHIRE AND EAST WORCESTERSHIRE INSTITUTE OF MINING ENGINEERS.—The members of this Institute, on Monday, paid a visit to the electric generating station of the South Staffordshire Tramway Company. The manager (Mr. A. Dickinson) gave the deputation a full description of the system and of the appliances at the works, and the visit afforded much interest to all present.

SUNDERLAND.—The Highways Committee of the Town Council have adopted by six votes to three the Electric Lighting Committee's report as to electric lighting extensions in the borough. The report recommends that the Thornhill and Christ Church districts be lighted electrically at the estimated cost of £3,000.

TELEGRAPHIC EXTENSION.—The Scottish Office notify that telegraph facilities are to be provided immediately from Gairloch to Badachro and other parts of Ross-shire. The Treasury has for some time past been asked to provide increased telegraphic communication in the western parts of Ross-shire and throughout the Island of Lewis, and the work is to be commenced immediately.

TRAIN LIGHTING.—The Directors of the Barry Railway Company are making arrangements for lighting the whole of their passenger trains electrically. For testing purposes the Company recently attached a first and second-class coach, especially fitted with electrical appliances, to one of the trains, and the experiment proved highly satisfactory. The supply for the coaches will be entirely independent for each. It is expected that the whole of the passenger trains on the Barry railways will shortly be lighted by electricity.

WHITECHAPEL (LONDON, E.).—The District Board of Works, at their meeting on Monday, decided to oppose the application of the Capital and Counties Electricity Supply Company for a Provisional Electric Lighting Order for Whitechapel. It will be remembered that the Board obtained a Provisional Order about two years ago, but has done nothing to comply with its provisions.—Mr. Catmur moved that the question of the introduction of the electric light into the district be referred to the Streets Committee for consideration and report, and this was agreed to with one dissentient.—Mr. Barham stated that, in his opinion, the Board would be able to supply the district with current 2d. per unit cheaper than a private company could.

COMPANIES' MEETINGS AND REPORTS.

Eastern Telegraph Company (Limited).

The forty-sixth half-yearly general meeting of this Company took place yesterday (Thursday) at Winchester House, Old Broad-street, London, under the presidency of the Marquis of Tweeddale.

The SECRETARY (Mr. George Draper) having read the notice calling the meeting, the report of the Directors was taken as read.

The CHAIRMAN said that it had been necessary to hold the meeting a few days later than usual, but this would not occur again, and they might calculate upon the meeting next year being held at the usual time. The Chairman was unavoidably absent on that occasion, it being the polling day for the Wick Burghs, and he was sure they would all join in expressing the hope that Sir John Pender might accomplish his aim and be successful. That was their forty-sixth meeting, and Sir John had presided on every occasion excepting the present. He proposed to follow the example which Sir John had set them at their meetings in dealing with their affairs. The gross revenue for the half-year under review—to March 31st last—had amounted to £420,526, being an increase of £31,212 on that of the corresponding period of 1894. There had been a small decrease in the traffic with India, but a considerable increase in the traffic beyond—to Australia and China. There was also a marked increase in the traffic with South Africa, attributable, no doubt, to the activity in mining business which had prevailed there for so long. At their last general meeting the Chairman announced that the Eastern and South African Company (in which their Company was largely interested) was about to complete an arrangement with the Governments of Great Britain, the Cape of Good Hope, Natal, and the South African Republic, as well as with the British South Africa Company, for a continuation of a portion of the subsidies now payable for telegraphic communication with South Africa, in consideration of a reduction of the tariff over the associated companies' lines between Europe and South Africa. The negotiations were brought to a satisfactory conclusion, and, as bearing on this point, he read a telegram from Sir John Pender expressing his great regret at not being present at the meeting, and stating that he (Lord Tweeddale) could "tell the shareholders that arrangements just completed with the Cape, Natal, and the Transvaal insure us 15 years' prosperous traffic." That was the consideration they had received for a lowering of the tariff. The rates were reduced from 8s. 9d. to 5s. per word for public telegrams, and from 2s. 2½d. to 1s. 6d. per word for Press telegrams. The accounts now submitted were not affected by the reduction, which came into operation on April 1st last, but the result so far might be considered satisfactory to all the parties to the Agreement, as well as to the telegraphing public. The total ordinary expenses for the half-year had been £98,060, or an increase over those of the corresponding period of 1894 of £3,220. From this increase, however, must be deducted about £2,293 for the proportion of stationery charged against this half-year's accounts, as fully explained at the last two general meetings. The comparison of one half-year with another would in future be easily made, as each period would bear its proper share of the annual cost. The actual increase in the ordinary expenses was therefore only about £927, notwithstanding a very large increase in the number of messages to be dealt with—an increase of 500,000 words, and of very nearly 100,000 messages. The working expenses at the stations had been £81,22?, or an increase of £4,579, but, deducting the item of stationery just referred to, the net increase under this head amounted to only £1,396, which was mainly due to the salaries and allowances of the larger number of staff required to cope with the additional traffic, and also to the annual promotions of the other members of the staff. They took great pains to make their employés comfortable wherever they might be stationed, and in return they looked for an active and zealous discharge of their duties. In this they had not been disappointed, and he questioned if any service could show a body of men more efficient and animated with a desire to do their duty to their employers. The expenses attending repairs and renewals of cables had been £52,730, or £3,070 more than in the corresponding period of 1894. The ordinary expenses of the ships for the half-year had been about the same as in the corresponding period of 1894, notwithstanding that they had been actively employed in the half-year under review. The credits received from other companies for the hire of their ships showed an increase of about £8,000, so that the increased expenses attending repairs to cables were due to their having laid an exceptionally large quantity of new cable—about 300 miles—into the original Aden-Bombay section. It was interesting to know that this section, which was laid so far back as 1870, was now, with the repairs in question effected, in good working order. The depreciation of spare cable amounted to £3,222, or an increase of £844, but this item must necessarily vary according to the stock of cable in the tanks from time to time, but it was kept as low as possible compatible with the efficiency of their service. The amount carried to maintenance ships' reserve fund was £9,000, or an increase of £4,000. This increase was really necessary in order to strengthen this fund in view of expenses which they saw coming before them. They had made a profit, as he had said, from the hire of their ships during the half-year, and they thought that the maintenance ships' fund should have the benefit of any profit the ships might earn. The net result of the half-year's work was that, after providing the usual amount for interest on debentures, debenture stock, and Preference shares, they were able to recommend the usual final dividend of 1¼ per cent., and a bonus of 1¼ per cent. making, with the interim dividend already paid a total distribution of 6¼ per cent. for the year ended March 31st last, and to carry the sum of £100,000 to the general reserve fund against £110,000 in 1894. They had also, in pursuance of an arrangement which was approved by the shareholders some time back, applied a further sum of £50,666 from the reserve fund in reduction of the cost of the Aden-Bombay No. 3 cable and other expenditure chargeable to capital. The total amount applied from reserve fund now amounted to £1,451,718, and their capital account, with the exception of some additions to buildings, practically remained at the same figure as it had done for many years past—a little over £6,000,000. Although their general reserve fund was a very substantial sum, and the securities in which it was invested were higher in value than they cost the Company, yet the sum fell very far short of what they considered it should stand at, having regard to the number and age of their cables. It had been urged by speakers at some of their recent meetings that the Directors should raise money to provide for capital expenditure, and thus furnish a large sum available for dividend purposes. This, however, had not been the Directors' policy, which had been to keep down the capital account of the Company, to provide an adequate reserve, and at the same time to pay a good and, he thought he might say, a handsome dividend to the shareholders. This policy was, he believed, approved by the great body of their shareholders, and he saw no reason to expect that it would be altered. He observed from a return which had been made to him of the market value of their capital that on the 23rd inst. their Ordinary shares, which were of the value of £4,000,000, stood in the market at £6,700,000, and, taking the whole of their capital together—Ordinary and Preference shares and debenture stock—the full amount represented was £6,099,690, which stood in the market at the date mentioned at the valuation of £9,719,439, or an appreciation of 59 per cent. The Company was in a flourishing condition, the management was both efficient and economical, their traffics were improving, and their relations with the Colonies and foreign powers—thanks to their Chairman's tact and energy—seemed to be on the most satisfactory footing. He concluded by moving a resolution for the adoption of the report and accounts and the payment of the dividends recommended.

Mr. G. G. NICOL seconded the motion.

A short discussion followed.

The CHAIRMAN, in answer to Mr. Goodsall, stated that the 300 miles of new cable referred to had been laid in different parts of the Aden-Bombay cable. In reply to Mr. Baynes, he said that he could only repeat what was stated by the Chairman at their last meeting—that as soon as the reserve fund was sufficiently large, the Directors would be only too glad to pay a higher dividend to the Ordinary shareholders.

The resolution was then unanimously adopted.

On the motion of Mr. BAYNES, seconded by Mr. H. T. BURGESS, a cordial vote of thanks was passed to the Chairman, Directors, and staff, both speakers expressing a hope, amid cheers, that Sir John Pender would return from the North successful.

The CHAIRMAN, acknowledging the vote, remarked that Sir John Pender would be extremely gratified at the kindness which had been displayed towards him by the meeting.

The proceedings then terminated.

[A full report of this meeting will appear in our next issue.]

West African Telegraph Company (Limited).

The tenth ordinary general meeting of this Company was held yesterday (Thursday) at Winchester House, Old Broad-street, under the presidency of Sir Henry C. Mance, C.I.E.

The SECRETARY (Mr. John Cambrook) read the notice calling the meeting.

The CHAIRMAN: Gentlemen, the duty of presiding here to-day has fallen to me in consequence of the absence of our Chairman, Sir John Pender, in the North, where he is very busy electioneering. I am sorry he is not able to be present with us to-day, because during the last two or three meetings the results we have submitted have not been completely satisfactory to the Ordinary shareholders, and I should have been pleased if it had fallen to his lot to communicate to you the position when better prospects appear to be opening out before us. I feel sure that nothing but the fact that it happens to be the polling day at Wick to-day would have prevented our Chairman from being in his usual place. There is another point I should like to refer to before passing to the accounts—namely, the loss we have sustained by the death of our late colleague, Mr. Thomas Fuller. Mr. Fuller had not been more than a year or two on this Board, but he had been closely connected with us in consequence of being the Managing Director of the African Direct Company, with whom we have mutually advantageous working arrangements. He had been intimately connected with the telegraph business in this city for more years than I can remember, and I am sure that he will be greatly and sincerely missed by a large circle of friends. You have all had the report and accounts in your hands for some time, and I presume that, in accordance with your usual custom, you will take them as read. That being so, I pass on to make a few remarks, which appear to me desirable, on some of the items. The gross revenue for the year ended December 31, 1894, amounted to £64,761, as against £61,847 for 1893, showing the very satisfactory increase of £2,914. Analysing the receipts from various sources, we find an increase in some classes of local traffic and a decrease in others. The principal increase in the message receipts is derived from the joint purse arrangement we have with the other companies associated with the South African telegraph connections with Europe. The loss on exchange amounted to £6,419, but in connection with this item it is satisfactory to note that this amount, although still large, and representing 2 per cent. or 3 per cent. on the capital of the Company, is much less than it was last year—less by £1,332, and we hope that there will be a further improvement in this respect. The total working expenses for 1894 amounted to £17,286, as against £18,829, or a decrease of £1,543. I am glad to state that this decrease has been effected while our efficiency has increased. The principal

Digitized by Google

decrease is in the expenses at the stations, nearly all the items under this head showing satisfactory decreases. The expenses attending repairs and renewals of cables amounted to £13,473, as against £31,234, or a decrease of £17,761. Although the diminution seems large, it must be remembered that we are making comparisons with a year when the expenditure under this head was abnormally high. The item of £13,473 for this year is still heavy, owing to the number of repairs required on the various sections of our cables. Looking therefore to the fact that after nine years' working our reserve fund only amounted to £21,775 at the end of last year, your Directors' after very mature consideration, arrived at the conclusion that they would be acting in the best interests of the Company in recommending you to carry the whole balance of net revenue to the reserve fund, thereby practically replacing the amount which we found it necessary to withdraw from that fund to balance our revenue account at the end of last year. This, I think you will agree with me, was undoubtedly the soundest policy to adopt, and we have no doubt that it will be approved by the general body of shareholders. We are glad to be able to announce that the revenue, so far as we have gone, and the expenses on account of repairs, both justify us in paying a small interim dividend on account of the present year's working, and we can only hope that in future the present condition of affairs will be at least maintained, so as to enable us to pay dividends regularly, after providing a fair contribution to the reserve fund. I had occasion at our last annual meeting to make a few remarks, and I ventured to predict that before long we should rejoin the ranks of dividend-paying companies. I am glad to find that my prophecy is correct. The circular which you all received with the report and accounts will, I hope, have been satisfactory reading to you, and I do not think there can be any question as to the prudence of putting the whole of the surplus amount available from last year to the reserve fund. I think that until a telegraph company has a substantial reserve fund it is not lifted out of the range of speculative business. I think we may say that we are now getting fast into a sound financial condition. Our reserve fund is higher than it has ever been before, and our debentures obtain a better price in the market. These results have been obtained notwithstanding the depreciation in silver and also our bad luck in the matter of repairs. We have now a telegraph steamer, the "Duplex," stationed on the coast. We have a very economical arrangement by which she is maintained, and, if interruptions do occur, I think that they will be repaired at a minimum cost and the least possible expenditure of time. I may also mention that during the year there has been, in concert with the other companies working to the Cape, a reduction in the tariff, which has given great satisfaction to the community at the Cape, and I am glad to find that the results are entirely satisfactory to us up to the present. I think that that is nearly all I have to say, and I may briefly sum up the position. Our cables, I am glad to inform you, are in good working order; the efficiency of our system has been improved during the year, and it is most gratifying to the Board to be able to say that the health of the staff is good. I have already pointed out the decrease in our working expenses and in the loss by exchange. On the other hand, there is an increased traffic, and judging from the reports from the Cape as to the sound condition of the gold industry now, there is every reason to expect that the improvement will be maintained. With these remarks I beg to move—

"*That the report and accounts for the year to December 31, 1894, submitted to this meeting, be and they are hereby received and adopted.*"

The MANAGING DIRECTOR (Mr. J. Denison Pender) briefly expressed his pleasure in seconding the motion.

The resolution was carried unanimously.

The CHAIRMAN then stated that in accordance with the Articles of Association two of the Directors retired, and he had much pleasure in proposing—

"*That Robert Kaye Gray, Esq., and the Hon. A. G. Brodrick be and they are hereby re-elected Directors of this Company.*"

The MANAGING DIRECTOR seconded the resolution, which was carried unanimously.

On the motion of Mr. A. HENDERSON, seconded by J. F. EAST, the auditors, Messrs. Deloitte, Dever, Griffiths and Co., were re-elected for the current year at a remuneration of fifty guineas.

A SHAREHOLDER proposed a vote of thanks to the Chairman and Directors. He regretted that Sir John Pender was unable to be present, as that gentleman had always conducted the business in such an efficient and courteous manner. It was, however, very important for him to endeavour by his personal efforts to secure his seat in Parliament.

Mr. HENDERSON seconded the motion, which was carried unanimously.

The CHAIRMAN: I have to thank you on behalf of the Directors, and I shall have great pleasure in being the medium of communicating the expression of your kind wishes to Sir John Pender.

The proceedings then terminated.

Telegraph Construction and Maintenance Company (Limited).

A half-yearly general meeting of this Company was held on Tuesday at the offices, Old Broad-street, under the presidency of Admiral Sir G. H. Richards, K.C.B.

The SECRETARY (Mr. E. Dickens) having read the notice calling the meeting,

The CHAIRMAN said: Gentlemen, at these half-yearly meetings you know we have no accounts to present to you, and, as a matter of fact, that means that there is no business to present. At the same time, we are very happy to see you on these occasions, and to give you any information that we are able to impart to you in regard to the affairs and the progress the Company for the six months that are ended. I regret that we have not much to give you. Perhaps the best thing I can say is that we shall pay you to-morrow morning the usual dividend which we have distributed for a great many years at this season, that is to say, 12s. per share, or at the rate of 10 per cent. per annum. I cannot say that this has been a good year for the manufacture of telegraph cables, which, as you know, are not an article of everyday use—I might say they are not an article of every year use. What I mean by that is that we do not look forward every year to get any very large orders for telegraph work. Of course, cable is made every year, but we do not expect every year to be able to say that we have done any very great work. However, it is not at all an unusual thing to have a slack time occasionally in making such articles as submarine cables. As regards our general trade—the gutta-percha work—that has gone on pretty much as usual at this time of the year; it is slightly better than it was at this time last year. Our factories, our ships, and our machinery are in good and efficient condition, and we are quite ready for any work that we may receive an order for; and we can only hope that we shall not be long unoccupied. This is really all I have to tell you, gentlemen; but if anything suggests itself to you to ask I shall be very glad to give you any information I can. As I have said, however, there is really very little to say. After a pause, he added: If no one has anything to say, the business of the meeting is at an end.

Mr. CROFT said he desired to move a vote of thanks to the Chairman and Directors for the great attention they had given to the affairs of the Company, and he would like to join in this expression of thanks the officers of the Company generally. He thought that what the Chairman had said about the work being rather slack went to confirm the opinion which the Chairman and his predecessors had always expressed to the shareholders regarding the wisdom of the policy of not dividing their profits up to the hilt. He believed that the Company had a very large reserve, and he thought that what the Chairman had stated showed the very great wisdom of keeping that reserve at as large an amount as possible so as to enable the Directors to maintain the dividend which the Company had been paying for a great many years. He regarded theirs as one of the best managed companies in the City of London.

Colonel GARDNER seconded the motion, which was carried unanimously.

The CHAIRMAN, in returning thanks, expressed a hope that the Directors might have better news to tell the shareholders at their next meeting.

Direct United States Cable Company (Limited).

The report of the Directors of this Company for the six months ended June 30th, to be presented at the thirty-sixth ordinary general meeting, to be held at Winchester House, 50, Old Broad street, E.C., on Tuesday, the 30th inst., at 2 o'clock, is as follows:—

The present report and statement of accounts, with the accounts to December 31st, presented at the meeting on January 25th last, show the financial result of the eighteenth year's working of the Company. The half-year's revenue, after deducting out-payments, amounted to £37,653 2s. 4d., compared with £34,843. 9s. 4d. for the corresponding period of 1894, an increase of £2,809. 13s. The expenses for the same period, including income tax, but exclusive of cost of repairs of cables, amounted to £18,909. 0s. 10d., leaving a balance of £18,744. 1s. 6d. as the net profit, or with £1,807. 19s. 3d. brought forward a total of £20,552. 0s. 9d. For the same period of 1894, the expenses amounted to £18,750. 3s. Three quarterly interim dividends amounting to £18,213 have been declared and paid during the financial year, and a final payment of 2s. per share is now proposed, making, with the three interim dividends, 2 per cent. for the year, being a total distribution of £24,284. After transferring £7,000 to the reserve fund account, the balance of £1,410. 0s. 9d. is carried forward.

Repairs of the Company's cables have cost £1,730. 7s. 4d. This amount, together with £673. 14s. 8d. written off the buildings account, Ballinskelligs, in respect of old buildings pulled down, have been debited to the reserve fund account, the balance of which, with the addition of interest, profit, and amount transferred from revenue account, now stands at £298,369. 18s. 10d.

Mr. Charles E. Günther and Admiral the Hon. Sir Henry Keppel, G.C.B., D.C.L., seek re-election as Directors, as do Messrs. Deloitte, Dever, Griffiths and Co. and Messrs. J. and J. Sawyer and Co. as auditors.

Globe Telegraph and Trust Company (Limited).

The report of the Directors of this Company, to be presented to the twenty-second ordinary general meeting to be held this day (Friday), at Winchester House, London, E.C., at 12 o'clock, states that the net revenue of the Company for the year ended 18th July, after deduction of expenses, amounts to £179,465 6s., or, with a balance of £527. 2s. 4d. brought forward, £179,992. 8s. 4d. From this amount there has been distributed £123,361. 5s. 5d. in interim dividends, leaving an available balance of £56,631. 2s. 11d. The Directors recommend a final dividend of 3s. per share on the Preference and 3s. 3d. per share on the Ordinary shares, making, with previous distributions, a total for the year of 6 per cent., less income tax, upon the Preference, and 4½ per cent. net (against 4½ per cent. for the preceding year) upon the Ordinary shares, the balance forward being £1,238. 3s. 4d., against £527 2s. 4d. last year. Since the last meeting a further sum of £38,592. 9s. 7d., resulting from the paying off of the Direct Spanish Telegraph Company's Six per Cent. Debentures, has been invested. Sir Henry D. Gooch, Bart., has resigned his seat at the Board, and it is not proposed to fill the vacancy at present. Sir John Pender, G.C.M.G., and the Hon. St. John Brodrick, M.P., offer themselves for re-election as Directors, as do also the auditors, Messrs. Deloitte, Dever, Griffiths and Co., and Mr. William Griffith, B.A., barrister-at-law.

City and South London Railway Company.

The report of the Directors of this Company is issued for the half-year ended June 30th last, and will be submitted to the half-yearly meeting to be held at Winchester House, Old Broad-street, E.C., on Monday next, at three o'clock.

The report states that the receipts from all sources for the half-year amounted to £24,401. 15s. 8d., and the cost of working to £15,019. 16s., leaving a profit of £9,381. 19s. 8d. With the balance brought forward the net revenue account shows an aggregate total of £10,379. 8s. 8d. After making provision for the Debenture and Debenture Stock interest, a balance remains available for dividend of £6,420. 16s. 2d. Out of this sum the Directors recommend that the full dividend of 5 per cent. per annum be paid on the Preference shares, and a dividend at the rate of 1⅛ per cent. per annum be paid upon the Consolidated Ordinary Stock, leaving £964. 11s. 2d. to be carried forward.

The following table shows the number of passengers (exclusive of season ticket holders) carried in each half-year since the opening of the railway :—

Half-year ended	Passengers.		Receipts (inc. season tickets).
December 31, 1890 (11 days)......	165,000	...	£1,568 3 9
June 30, 1891	2,412,343	...	19,403 6 9
December 31, 1891	2,749,055	...	19,798 16 6
June 30, 1892	2,813,162	...	20,931 4 2
December 31, 1892	3,117,602	...	22,002 17 5
June 30, 1893	3,146,656	...	22,458 6 9
December 31, 1893	3,093,351	...	22,067 14 10
June 30, 1894	3,383,154	...	23,564 10 6
December 31, 1894	3,275,649	...	23,540 12 4
June 30, 1895	3,113,199	...	23,711 5 8
Total since the opening of line..	27,269,171		£199,046 18 8

During the first three months of the present year there was a satisfactory growth of the traffic on the line, but the very hot and fine weather of the last three months affected it so much that the increase was not only checked, but a small decrease resulted as compared with the same quarter last year. The receipts, however, still show a small increase.

In accordance with the authority given at the last half-yearly meeting, detailed plans have been prepared for the extension to Finsbury-pavement, and negotiations have been entered into for the purchase of some of the property, but the arrangements are not yet sufficiently completed to enable a report to be made to the shareholders on the present occasion.

During the past six months a further sum of £23,200 Terminable Mortgage Debenture Bonds has been paid off. The Bill for the extension of time for the works of the Clapham Extension Act, 1890, and for other purposes, received the royal assent on May 14th last. A contract has been let for the construction of the new siding at Stockwell. This, when completed, will enable the work at that station to be carried on with greater economy and convenience.

Edison and Swan United Electric Light Company (Limited.)

The following report is issued by the Directors of this Company for the year ended June 30th last, and will be presented to the ordinary general meeting to be held at the Cannon-street Hotel, London, E.C., on Monday next, at two o'clock :—

The profit and loss account shows a credit balance of £25,876. 3s. 2d., and after providing for the interest accrued upon the £100,000 Debenture Stock, there remains a balance of £21,376. 3s. 2d. available for distribution. An interim dividend at the rate of 5 per cent. per annum having already been paid in respect of the first half-year, to December, 1894, a further payment at the same rate in respect of the second half is recommended, the balance of £3,702. 5s. 2d. being carried forward. The business of the Company during the year has been satisfactorily maintained, notwithstanding the severe competition which has set in since the expiration of the Company's patents.

The liquidation of the Swan United Electric Light Company (Limited) is now practically completed, and the final meeting for winding up will shortly be held.

The Directors announce the resignation of Mr. Shelford Bidwell, F.R.S., and the election of Mr. Joseph Wilson Swan, F.R.S., in his place. The Earl of Lichfield and Mr. Ernest Villiers seek re-election as Directors, as do the auditors, Messrs. Welton, Jones and Co.

At the meeting a resolution to strike out the present Section 87 of the Articles of Association and substitute a new section as under, will be proposed, and, if passed, will be submitted to a subsequent extraordinary general meeting for confirmation as a special resolution :—

87. The amount from time to time declared by the Board as available for dividend, including the amount (if any) recommended by them to be withdrawn from reserve for equalisation of dividends, shall be applied as follows :—

(1) There shall be first set aside thereout a sum equal to a preferential cumulative dividend of 7 per cent. per annum on the aggregate amount for the time being paid or credited as paid on the "A" shares.

(2) Out of the sum so set aside there shall be paid a preferential cumulative dividend at the rate of 5 per cent. per annum on the amounts paid or credited as paid on the "A" shares without distinction.

(3) Subject thereto, there shall be paid out of the sum so set aside a further cumulative dividend at the rate of 2 per cent. per annum on the amount paid or credited as paid on the "A" shares, provided that until all the "A" shares be fully paid, no "A" share, whether fully paid or not, shall for the purpose of this subsection be deemed to have paid upon it more than the amount paid up or called up upon the "A" shares for the time being having the least amount called up or paid thereon.

(4) The balance of the sum so directed to be set aside shall be carried to the reserve fund.

(5) The residue of the amount declared to be available for dividend, after setting aside the sum mentioned in Subsection 1, shall be applied in payment of dividends *pari passu* on the amounts paid up or credited as paid on the "A" and "B" shares, but so that, for the purposes of this subsection, the amounts to be deemed paid up on the "A" shares shall be ascertained as in the case of Subsection 3.

The following dividends are announced by the Edison-Swan Company:— On the 89,261 Ordinary shares, 1s. 6d. per share ; on the 12,139 fully-paid "A" shares allotted to the Swan United Company, 2s. 6d. per share ; and on the 5,000 fully paid "A" shares allotted to the Edison Company, 2s. 6d. per share. This distribution, together with the interim payment already made in respect to the first half-year, will be equal to 5 per cent. for the year. The dividend warrants will be posted on August 12th.

Thomas Parker (Limited).

The first annual report of the Directors of this Company, which has just been issued, is as follows : The Company was formed in April, 1894, but only commenced work about the end of January last. By far the larger portion of the management and working expenses, staff salaries, &c., having been incurred in the development of the business, planning, designing, and erection of the buildings and plant, the preparation of loose tools, patterns, &c., the Directors might have charged a very considerable proportion of these expenses to plant, &c., but have preferred to charge them all to a general account, the balance of which is £4,143. 6s. The Directors propose to transfer £3,000 of this amount to the goodwill and development account, and to treat the balance (£1,143. 6s.) as preliminary expenses, to be dealt with in future accounts. Many important contracts and orders have been already secured, and the trading prospects for the year are such as to give the fullest satisfaction. After lengthy negotiations the actions between the Electric Construction Company (Limited) and Thomas Parker (Limited) and the points in dispute have been settled on terms, the Directors think, highly favourable to their Company. The retiring Directors are Messrs. Mander, Graham and Thomas, who offer themselves for re-election, as do the auditors, Messrs. Allen Edwards and Smith.

Gulcher (New) Electric Light and Power Company, Limited (in Liquidation).

An extraordinary general meeting of this Company is to be held at 73, Lombard-street, London, E.C., on Monday next, at 2:30 p.m., to receive the account of the liquidator (Mr. C. Fitch Kemp), showing his acts and dealings and the manner in which the winding-up has been conducted, and to consider, and if approved to authorise, the acceptance of an offer received by the liquidator to purchase of and from him, at the price of £2. 10s. per share, 680 Ordinary shares of £10 each, fully paid, in Easton, Anderson and Goolden (Limited).

The statement of receipts and payments issued by the liquidator gives little hope of any ultimate payment to the trade creditors of the Gülcher Company, and Mr. Kemp in his report has a doleful tale to tell of promises made and unfulfilled, of great expectations and small realisations ; and those who, at the outset, cast doubts upon the sanguine statements of Mr. De Castro and those responsible for the management of the Company find their gloomy prognostications fulfilled to the letter. Mr. Kemp states that he accepted the position of liquidator of the Company upon the basis that cash assets, viz., the stock-in-trade and plant, and a debt owing to the Company in New Zealand from the New Zealand Electrical Syndicate, would be sufficient to pay off the First Debentures, that the uncalled capital of the Company would be sufficient to pay off the Second Debentures, and would probably provide a surplus of cash which would pay a substantial dividend to Third Debenture holders, and that, ultimately, the unsecured creditors would be fully paid, and some return would be made on the share capital, when time had been given to realise the holding of the Company in the shares of the New Zealand Electrical Syndicate. This forecast of liquidation has entirely failed of realisation owing to causes which Mr. Kemp sets out in his report, but which we may here say are mainly connected with a member of the late Board of Directors.

The attention of the contributories is called to the resolution which was passed at the meeting held on August 1st last, authorising Mr. Kemp to enter into an arrangement with Messrs. Easton, Anderson and Goolden (Limited) for the sale of the Gülcher Company's plant, machinery and stock-in-trade at the price of £12,500, payable as to £5,700 part thereof in cash, and as to £6,500, the balance thereof in 680 shares of £10 each, fully paid, in Easton, Anderson and Goolden (Limited). The cash paid was alone greater than the liquidator could have expected to receive at a break-up price. The shares, therefore, were taken for what might be their value, it being well known that there was no market for them at that time, and that they were not earning a dividend. An offer has been received of 5s. in the £ for these shares, that is, £1,700, and if this meeting authorises the liquidator to accept that offer he will, after discharging the expenses of the liquidation to date, apply the moneys obtained in further reduction of the £2,500 which remains owing on the security of the First Debentures, as it is obvious that until those First Debentures are discharged there can be no payment to the unsecured creditors.

The liquidator, more sanguine than most folks, does not take at all a despondent view of the ultimate realisation of the assets of the Company, but cannot hold out the hope that funds will reach his hands available for dividend at an early date.

NEW COMPANIES, STATUTORY RETURNS, &c.

AVELING AND PORTER (LIMITED).—This Company was registered on July 16th with a capital of £150,000, in £10 shares, to acquire and carry on the business of engineers, boiler makers and ironfounders now carried on at Rochester, Kent, and London by Messrs. "Aveling and Porter," and to enter into an agreement, dated July 11th, made between T. L. Aveling and R. T. Porter, and Harry Pitts for the Company.

ELECTRIC OZONE SYNDICATE (LIMITED).—This Company was registered on July 19th with a capital of £12,000, in shares of £10 each, to purchase certain letters patent, patent rights and inventions granted to or obtained by Emile Andreoli in England and abroad, for generating and dealing with ozone by means of electricity and using ozone for various purposes, to enter into an agreement for the purpose of such acquisition, and to carry on the business of mechanical and electrical engineers, and manufacturers of and dealers in all apparatus and things required for or capable of being used in connection with the working of any patents, patent rights or inventions for the time being belonging to the Company, or in which the Company is interested. The subscribers, with one share each, are: C. Hanbury, F. J. Hanbury, W. P. Henderson, E. Andreoli, R. Arnot, W. L. Castleden, and G. Andreoli.

LIGHTING CORPORATION (LIMITED).—This Company was registered on July 18th with a capital of £250,000, in £1 shares, to maintain and uphold any appliances, apparatus or plant requisite for electric, gas, oil and any other methods of lighting, and to carry on the business of manufacturers of and dealers in incandescent lights and other apparatus for increasing the illuminating power of gas, spirits, oil, and other light and heat-producing agents, suppliers of light, heat, electricity and motive power, electricians, chemical manufacturers, mechanical engineers and ironmongers. The subscribers, with one share each, are: H. R. Hartley, F. Dawkins, H. H. A. Herwig, C. Darch, E. E. Culley, T. R. Bastard, and J. Baxter.

NEW PHONOPORE TELEPHONE COMPANY (LIMITED).—This Company was registered on July 19th with a capital of £10,000, in 9,000 Ordinary and 1,000 Founders' shares of £1 each, to purchase or otherwise acquire any patents, licences or concessions conferring an exclusive or limited right to use any invention or improvements in telephones, or in telephonic, telegraphic or other electrical apparatus, and in particular to enter into an agreement for the acquisition of the benefit of certain existing inventions mentioned in an agreement to be made between the Phonopore Company (Limited), and this Company or its representative, and to use, exercise, develop, grant licences in respect of or otherwise turn to account any such patents, licenses or concessions. The subscribers, with one share each, are H. Seebohm, M. Mocatta, T. J. Nash, C. E. Spagnoletti (electrical engineer), J. G. Chappell, W. F. Liddell, and Charles Isaac, of Faraday House, Charing Cross-road, London, W.C. (secretary).

RECOVERED RUBBER WORKS (LIMITED).—This Company has been registered with a capital of £20,000, in £10 shares, to acquire the business now carried on by Messrs. Grimshaw Brothers at Clayton, Manchester, and to carry on the business of rubber dealers.

J. E. H. ANDREW AND COMPANY (LIMITED).—The annual return to May 29th has been filed. The nominal capital is £40,000, in £20 shares. 1,465 of these have been taken up, 300 have been issued as fully paid, and the full amount has been called on the remainder.

HASTINGS AND ST. LEONARDS-ON-SEA ELECTRIC LIGHT COMPANY (LIMITED).—The annual return to June 6th has been filed. The capital is £50,000, in £10 shares, and 2,722 have been allotted, and the full amount has been called thereon. £5 has been paid on five forfeited shares.

J. H. PICKUP AND CO. (LIMITED).—The annual return to May 31st has been filed. The whole nominal capital of £15,000, in £5 shares, has been taken up, and of these 800 have been issued as fully paid. £3 per share has been called on the remaining shares.

REUTER'S TELEGRAM COMPANY (LIMITED).—The annual return to June 12th has been filed. Out of a nominal capital of £100,000, in £8 shares, 11,839 have been allotted, and the full amount has been paid thereon.

SAXBY AND FARMER (LIMITED).—The annual return to April 15th has been filed. The capital is £25,000, in £10 shares, of which 2,021 have been taken up. Of these 1,800 have been issued as fully paid, and the full amount has been paid on the remainder. Mr. Correll Farmer, of Boxwood, Billingshurst, holds 1,948 of these shares.

SHEFFIELD ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual return to April 18th has been filed. The nominal capital is £98,000, in £7 shares, of which 8,625 have been taken up. Of these, 4,000 have been issued with £5 per share considered as paid, and a call of £2 per share has been made on the whole on them.

SINGLE-WIRE MULTIPLE TELEPHONE SIGNAL COMPANY (LIMITED).—The annual return to June 14th has been filed. The nominal capital is £5,000, in £10 shares, and 254 have been taken up. The full amount has been called and paid.

CITY NOTES.

CAPE TOWN AND SUBURBAN ELECTRIC LIGHTING SYNDICATE (LIMITED).—The second annual general meeting of this Syndicate was recently held at Cape Town, Mr. R. S. Solomon presiding. The Chairman, in moving the adoption of the report and accounts, congratulated the shareholders on the increasing prosperity of the Syndicate. They had very few hitches during the past year, there had been no serious complaints, and people were very pleased with the light. They had spent some £300 or £400 in extending their mains, and had issued the remainder of their capital for the new plant, which had now been ordered. At present all their power was taken up, and in order to meet the increased winter demand they were obliged to have recourse to a temporary plant. To show the steady increase in the demand for current, the Chairman said they started last year with 857 lamps, this year they had 2,580, and over 300 were waiting to be installed. Their success had been very great, and he thought their future was assured. Their engineers were to be congratulated on the results of their labours. A dividend at the rate of 7 per cent. per annum was declared, which would take £1,281; a sum of £151 was allotted as Directors' fees, and a balance of £2. 10s. 10d. was carried forward out of a total net profit of £1,433. 11s. 10d. The additional plant which was now on order would cost about £7,000, and this would more than double the capacity of the present plant, and enable the Syndicate to considerably extend its operations. 7,000 shares had been issued by the Directors to provide for the purchase of this new plant, and they had experienced no difficulty in placing these shares at par amongst the existing shareholders. The report and accounts were adopted.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended July 21st were £831, against £839 in the corresponding week of 1894, a decrease of £8. The total receipts for the half-year amount to £2,594, against £2,600 for the corresponding period of 1894, a decrease of £6.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—The warrants for the interim dividend on this Company's Six per Cent. Preference shares have been posted.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have resolved, after providing for the dividend on the Preference shares, to recommend the payment of a dividend on the Ordinary shares at the rate of 8 per cent. per annum, free of income tax, for the half-year ended June 30th. This dividend is at the same rate as last year.

DETROIT CITIZENS' STREET RAILWAY.—The *Western Electrician* states that this Company has equipped the whole of its lines for working by electricity.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company announce that the coupons on their Five per Cent. Debentures, due August 1st next, will be paid on and after that date at the banking house of Messrs. Glyn, Mills, Currie and Co., 67, Lombard-street, E.C. Coupons to be left three days for examination.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).—This Company announce the payment by warrants on August 1st next of interest for the half-year ending July 31st on their Four per Cent. Mortgage Debentures. The transfer books will be closed from July 28th to August 1st inclusive.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The accounts of this Company for the past half-year show an available balance of £8,076, and the Directors have decided to recommend the payment of a dividend of 5 per cent. per annum on the Preference shares, and 2¼ per cent. per annum on the Ordinary shares, as against 1 per cent. per annum on the Ordinary shares for the corresponding period last year. The balance carried forward is £1,302, against £1,248. The traffic receipts of this railway for the week ended 21st inst. amounted to £1,226, against £1,034 in the corresponding week last year; increase, £192.

REDUCTION OF CAPITAL.—A petition for sanction to reduce the capital of the Phosphor-Bronze Company came before Mr. Justice Kekewich in the Chancery Division on Saturday last. The capital of the Company is £150,000, but, owing to commercial depression and trade competition (in respect of which £25,000 had been written off), and especially owing to the expiry of all the patents save one, which were purchased some years ago at a cost of £70,000, the Company asked for a reduction to £90,000. The judge, after a careful examination of all the items in respect of which depreciation was pleaded, gave his consent as asked for.

ST. JAMES'S AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED).—The share transfer books of this Company will be closed from July 24th to August 7th inclusive, preparatory to the payment of interim dividends on the Ordinary and Preference shares for the half-year ended June 30th.

SOCIETE ANONYME DES TRAMWAYS DU CAIRE.—This is the title of a Company just formed in Paris. The Company, which has a capital of £160,000, is to acquire a 50-years concession recently granted by the Egyptian Government for the construction and exploitation of about 12 miles of electric tramways on the Thomson-Houston overhead system in Cairo.

THE AMERICAN WESTINGHOUSE COMPANY.—In the report just issued, this Company estimates that the net returns for the past year were less than half what they would have been had business not been interrupted by the removal of their plant.

VENEZUELA TELEPHONE AND ELECTRICAL APPLIANCES COMPANY (LIMITED).—Coupon No. 10 of the Five per Cent. First Mortgage Debentures of this Company, due 31st inst., will be paid after that date, at the Consolidated Bank, Threadneedle-street, London, E.C., or at Messrs. Westendorp and Co.'s Bank, Amsterdam.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended July 19th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,078.

WESTMINSTER ELECTRIC SUPPLY CORPORATION (LIMITED).—The Directors of this Company have declared an interim dividend for the half-year ended June 30th at the rate of 5 per cent. The dividend is payable on September 1st next.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 898. [No. 14. Vol. XXXV.] FRIDAY, AUGUST 2, 1895. PRICE SIXPENCE.

NOTES.

Amidst the serried columns devoted in this issue to reports of speeches made by the Chairmen of various companies to their respective shareholders, none will be found more worthy of perusal than the four columns occupied by the remarks of Mr. James Staats Forbes at the meeting of the shareholders of the National Telephone Company on Friday last. The commander-in-chief of our only telephone company takes the perennial grumbling of the British public, the surrender of the trunk-wires to the Post Office, and the Telephone Committee in very good part; and well he may, for notwithstanding them all the telephone business has increased, is increasing, and does not seem likely to diminish. The growth of telephony in the United Kingdom cannot be better shown than by the statement that within the last six months nearly £150,000 has been spent on exchange extensions, and over 4,000 new lines have been erected. Londoners especially will be glad to hear that the annoyances inevitable to a change over from single-wire to double-wire circuits are nearing their end; by the close of the year the whole of London will be metallic-circuited.

From the strategic point of view there can be no denying that the National Telephone Company suffered a severe loss in being obliged to hand over its trunk system to the Post Office, though we suspect that these interurban wires, however profitable indirectly as a means of attracting subscribers, and knocking the bottom out of competitive schemes, were not in themselves particularly remunerative. This suspicion is strengthened by the cheery philosophy with which the President of the Company treats the loss of this branch of the business. At the same time we cannot help thinking that the astute controller of the fortunes of the National Telephone Company would have done well to have dissembled his joy a little more. The terms of the Agreement will, Mr. Forbes thinks, "prove to be extremely good terms, . . . because the Post Office are enabled to take risks in respect of the extension of this system which we should not have been inclined to take, but of which we shall have the benefit, while we shall be left free to develop what is our more special business—the conduct of this exchange work in the great areas. There is a great deal less risk in this work than in the expenditure necessary on great trunk lines. That is what the Government have to do . . .," and Mr. Forbes, not unnaturally, thinks it is "very wise" of the Government to undertake that part of the work. No doubt. This candid way of putting the matter does not tend to make us lament our persistent advocacy of Government purchase of the entire business when that course first became possible in December, 1890. Neither does it tend to lessen our regret that the case for municipal telephony was so inadequately placed before the Telephone Committee, the major portion of the anti-National Telephone Company evidence being, as Mr. Forbes contemptuously expresses it, given "in a considerably florid way."

The tale told by Mr. Mott to the shareholders of the City and South London Railway Company was of the customary character—reduced expenses, increased receipts, increased dividend; but all of microscopic proportions. The locomotive expenses per train mile are now 6·1d. as against 6·22d.; the receipts per train mile have grown from 2s. 1$\frac{1}{2}$d. to 2s. 2$\frac{2}{5}$d. Although the continued decrease in working expenses and the continued increase of income is a healthy sign, the rate at which the improvement takes place is so small that a 5 per cent. dividend would seem to be beyond the reach of any of the shareholders now living. It is therefore satisfactory, both on account of the shareholders and of the future of electric railways in this country—a future intimately connected with the degree of financial success attained by the pioneer enterprise—to learn that the northern extension of this line is under weigh, although at the present moment Finsbury Circus, and not the "Angel," Islington, will be the terminus. One result of this extension will be the running of heavier trains, and no further progress with motor-car trains has therefore been made, since motors which would suffice for the existing trains would probably not be equal to drawing the new ones. The lighting of the carriages is also to be improved—there is plenty of room for it. The fact that the increase of passenger traffic observable at the beginning of the year was immediately checked, and ultimately converted into a decrease by the advent of what the Americans call a hot-wave, seems to point also to the desirability of some improvement in the ventilating arrangements. A tunnel railway 50ft. to 80ft. below the surface has a natural tendency to be cool in summer and warm in winter. The problem of how to make the atmosphere in the tunnels and stations sweet and fresh should not, in view of the absence of smoke, steam, and fumes, be beyond solution.

The nervous and anxious state which for some time past has been apparent among the leaders of magnetic science may be taken as an indication that they perceive both the need for setting their house in order and the difficulty of the task. When physical science, by the unanimity of its disciples, has already pinned itself to the C.G.S. system, it would seem that there should be no uncertainty in the course to be taken in formulating the mathematics of magnetic science, were it not, on the one hand, that magnetism has its supremely important commercial applications, in which the scientific beauties of the offspring of that triangular parentage, C., G. and S., are of microscopic importance compared to the practical considerations of the draughting and workshop departments; and, on the other hand, that magnetic science has suffered from the mistakes of its partisans. In this last-named matter, troubles have arisen chiefly on account of misconceptions of and confusions between **B** and **H**; and there seemed to be some possibility of an unscientific system of magnetic units being foisted upon the electrical profession by those who had not sufficiently discriminated between these two things. But the matter of the settlement between commercial and scientific interests is more far-reaching, and less likely to be disposed of easily. There are three chief stumbling-blocks in the way of reconciliation: the ampere-turn, the terrible π and the British system of weights and measures. To the last of these no quarter need be given; many engineering firms have already replaced it, and it may be anticipated that in due time the replacement will become universal. As to π—that mathematical bogey—students of magnetic science must extract what consolation they can from the certainty that it will turn up either on its head or its heels, either in the numerator or the denominator; and the units of magnetic quantities may be arranged so that it will turn up with the minimum of inconvenience.

But the ampere-turn is the crux of the difficulty. Practical men have grown to regard this quantity as a very real and fundamental unit; while scientists must look upon it as a complex thing, only to be connected to their rational systems by a linkage of coefficients and equations. Yet we doubt if the practical man will ever surrender his ampere-turn; and the best that can be done is to adopt a system of units which will make those coefficients and equations least troublesome. Some suggestions towards a reconciliation, and the construction of a rational magnetic system, have been carefully compiled by Prof. Oliver Lodge, at the request of the Electrical Standards Committee of the British Association; and these we are able to publish this week. Prof. Lodge has proposed two alternative systems, and invites comment and criticism. Speaking briefly, and for ourselves, we should wish, with Mr. Baily, to see the unit of magneto-motive force made equal to one ampere-turn, even though at the cost of saddling μ with π. This would be of immense value to practical men; and it should seem of but trifling importance to theorists. In regard to the size of the units, the only practicable settlement will be to introduce a number of multiple and sub-multiple units for practical use.

The *Journal of Gas Lighting*, in a recent issue, expresses its conviction that "there seems to be a deplorable waste of power in electrical tramway systems, which requires stopping before this means of working can claim to be economical." The particular example of electrical tramway traction which has given rise to this sweeping statement is that which, after one year's working by the contractors, is now passing into the hands of the Municipality of Brussels. And the "deplorable waste" which our contemporary alludes to is thought by it to arise from the fact that a car which "a pair of Flemish horses could easily run away with" requires much more than two horse-power of engine plant to be allotted to it. Our contemporary has fallen into the common error, at one time more common than it is now, of supposing that in an economical system of electrical traction the amount of horse-power of engine plant ought to be comparable with the number of horses which would be required to keep the cars moving. There is, in reality, no sort of connection between the two things, as our gas friends would pretty soon discover if they tried to run the cars with gas engines. "What an enormous surplusage of electrical power, as compared with horseflesh, marks this installation!" cries our contemporary. Quite so. But it by no means follows that that surplusage is always in actual use, and it is quite erroneous to suppose there "must be something very crude about a system which needs 900 indicated horse-power to keep 22 tramcars moving." This power is not required to keep them *moving*; it is mostly a reserve to start them. Besides, while the "pair of Flemish horses" are running away with the car, there is, it must not be forgotten, a "surplusage" of several horses eating their heads off in the stables.

Cable Interruptions.—There are again no cable interruptions to report this week. The last interruption recorded occurred on June 13th last.

Regent Street Polytechnic.—Courses in Electrical, Marine, Civil and Mechanical Engineering at the Polytechnic School of Engineering, Regent-street, commenced July 17th.

Terrestrial Magnetism.—The Meteorological Institute of Utrecht has sent two of its members to the St. Gotthard to study the influence of height above the sea level on the terrestrial magnetism.

Electric Traction in Germany.—Plans, it is stated, have been prepared by the Union Electricitäts Gesellschaft for the conversion of the Hamburg-Harburg section of the Prussian State railways into an electric line.

Telephonic Communication between Germany and Belgium.—Arrangements for the establishment of telephonic communication between Brussels and Antwerp on the one side and Cologne and Aix-la-Chapelle on the other are now said to be practically completed.

Electric Traction in Austria and Hungary.—It is proposed to convert the Schwabenberg Mountain Rack Railway into an electric line, and to extend it from Budakesz as far as Anwinkel. Plans have been prepared for an electric local railway between Budapest, Foch, Wartzer and Hartyan.

Intrinsic Brilliancies of the Welsbach Mantle and Glow Lamp Filament.—According to Von Oechelhäuser, says the *Gas World*, a Welsbach lamp gives one candle for every 33 sq. mm. of its area. According to Bernstein, an electric glow-lamp filament gives off the same for each 4 sq. mm.

Electrical Utilisation of Water Power in Italy.—Messrs. Schuckert and Co., of Nuremburg, have submitted plans for the establishment of a central station, having a capacity of 1,500 H.P., in the important town of Bergamo, about 30 miles from Milan. The water power of the River Brembo would be utilised.

Digitized by Google

Oil Fuel.—According to an article in *Electrical Engineering*, by Mr. C. O. Billow, who was in charge of the fuel oil department at the Chicago Exposition, the average evaporation of the boiler plant was 98·99lb. of water per gallon of oil, the evaporation being from a hot water temperature of 212deg. to steam at 125lb. pressure.

A New Chair of Physics.—The trustees of the late Miss Margaret Harris have allocated a number of securities, valued at nearly £14,000, to establish a chair of Physics at University College, Dundee. The Council have resolved to immediately institute a chair of Natural Philosophy, and an appointment will be made before the beginning of next session.

A Student-built Engine.—It is reported, says the *Engineer*, that Messrs. Hall and Treat, two students of Cornell University, have built a quadruple-expansion engine, constructed for regular working at 500lb., but which has been worked up to 600lb. per square inch. The reported consumption is something under 10lb. of steam per horse-power per hour.

Evaporative Power of Refuse in Destructors.—Messrs. T. S. M'Callum and W. Naylor have recently published particulars of a trial of the evaporative power of town refuse at the Royton sewage works. The amount of ash and clinker formed during the trial was 46 per cent. of the weight of the refuse consumed, while the evaporation was only 0·40lb. of water per pound of refuse.

Public Telephone Stations for Berlin.—According to the *Berliner Tageblatt*, the Berlin Town Council has received an application for a concession to erect public telephone stations in different parts of the town. These stations are to take the form of small pavilions, containing several compartments fitted with telephones, and to be at the disposal of the public for a small fee.

Effect of Slow-Speed Street Cars in Brooklyn.—One effect, says the *Street Railway Journal*, of the reduced speed on the Brooklyn trolley roads has been an increase of traffic on the elevated roads of that city, and as a result, the wages of the employés of the Brooklyn elevated system (with the exception of the engineers and office clerks), which were reduced 10 per cent. in October, 1893, on account of the competition of the trolley roads, were restored to the old rates on June 1st.

Gas Engine Central Station in Chicago.—According to the *Western Electrician* of Chicago, the central station of the American Gas Engine Electric Company at Clark and Lake streets, Chicago, is nearing completion. This station contains gas engines of 400 I.H.P., directly belted to dynamos. The largest unit will be a 200 H.P. tandem engine, similar to those in the station at Belfast, which were described and illustrated in *The Electrician* of July 26th.

Curious Behaviour of an Electric Meter.—A curious phenomenon has, according to an American contemporary, lately been noticed in an alternating-current meter of well-known make. It was noticed that when the lamp load was off, the meter ran backward at a very slow rate, deducting about 200 watt-hours during a night's run. Complaint was made to the manufacturers, who stated that they had discovered this defect, and "that it was due to the case."

Appointment.—Since the death of Mr. F. N. Gisborne in August, 1892, the office of General Superintendent of the Canadian Government Telegraph Service, has remained nominally vacant, although Mr. D. H. Keeley has performed the duties of the office. By order of the Minister of Public Works the office has now been definitely filled by the appointment of Mr. Keeley, who thus becomes head of a department in which he has worked under his old chief for a very lengthened period.

Destruction of a Power House at Seattle, U.S.A.—By a fire which broke out on June 20th a considerable proportion of the buildings, machinery and rolling stock of the Consolidated Street Railway Company, at Seattle, U.S.A., were destroyed. The loss, which is estimated at between £15,000 and £20,000, comprises the whole of the rolling stock and supplies, and from 15 to 20 per cent. of the generating machinery, besides a substantial brick structure 250ft. in length and 60ft. wide. The origin of the fire is still undetermined.

Electricity for Californian Mines.—One of the most interesting features of the Grass Valley (California) electric transmission plant, says the *Engineering and Mining Journal* of New York, is the means thus furnished for operating a large number of mines which have been shut down for some time owing to excessive cost of power. Within a distance of from three to nine miles of the power plant are located 63 mining plants, requiring over 4,000 H.P. More than one-quarter of these are idle at the present time and will be largely benefited by this new enterprise.

German Wiring Rules.—At the recent annual meeting of the Verband Deutscher Electrotechniker, at Munich, the proposed wiring rules, of which we published an abstract in *The Electrician* of May 24th, p. 116, were referred to a special committee, consisting of representatives of the Reichanstalt, the Imperial Telegraph Department, the Vienna Association of Electrical Engineers, the Association of German Supply Stations, and several of the more important electrotechnical societies and fire offices. At the same meeting, the proposal for the introduction of uniformity in the matter of contact areas of fuses, and the screws for same, was accepted.

An Acetylene Standard of Light.—M. Violle has recently been engaged in a series of researches on acetylene which have led to the construction of a standard of light. He burns acetylene under a somewhat strong pressure in a burner to which air has easy access, and which gives a broad flame. M. Violle has, in this way, obtained a very steady brilliant white light. Before the flame he places a screen pierced with an opening of a given size, and in this way he considers that he has obtained a standard of light which for constancy, whiteness and brilliancy is comparable to his absolute platinum standard, and which ought, he thinks, make a safe and convenient secondary standard.

City and Guilds of London Institute.—The diploma of "Associate of the City and Guilds of London Institute" has been conferred by the Council of the Institute upon the following matriculated students who have this year successfully completed the full course of instruction at the Central Technical College:—Civil and Mechanical Engineering: H. S. Andrewes, F. G. Arnould, J. E. Chapman, H. E. Fenwick, C. S. Hainworth, E. W. Hainworth, B. H. M. Hewett, E. W. Hummel, F. T. W. Lewis, F. E. Morgan, R. E. Reeves, H. Robinson. Applied Physics and Electrical Engineering: J. M. Barr, S. Beeton, C. Brandeis, W. M. Carver, A. D. Constable, S. Gilford, F. S. Grogan, A. C. Hanson, G. S. Hewett, C. D. Le Maistre, P. G. Phelps, W. Reilly, W. Roberts, H. G. Solomon, R. J. J. Swann, C. P. Taylor, E. L. Thorp, E. L. Webb, N. J. Wilson. Applied Chemistry: W. G. Bennett, W. A. Davis, W. T. Gidden, C. Revis, E. M. Rich, P. Spencer.

Damage by Lightning.—During a thunderstorm on Friday last at Loftus, Cleveland, eight sheep were killed by lightning.—At Coble Dene, on Saturday last, a house was struck by lightning, the chimney being destroyed, part of the roof ripped up, and much damage done to the interior.—Violent storms occurred last week in many places in France. At Tours the lightning struck a house adjoining the post and telegraph office, and several of the telegraph and telephone wires were melted. The tower of the Convent of Breteche was struck by lightning. At the same moment, says the correspondent of the *Standard*, "an intensely strong spray of electric light" traversed the workshop of M. Bouyer, situated just opposite the convent, but on the other side of the Loire. Three women lost consciousness, and one of them remained in that condition two hours, while the two others were for some time paralysed in the right leg and side. The neighbourhood of Orleans suffered greatly from violent storms. The church tower of Saint Jean de Brayn was struck by lightning on Friday last, and a man was killed at Clery.

Electric Supply Meter Competition.—At a recent meeting of the Edinburgh Society of Arts the Society approved of a proposal by the Council to offer for competition a Keith prize of £50 for improvements in electric energy meters for domestic supply. Competitors will be expected to submit, in addition to a descriptive Paper, accompanied by detailed drawings, a

Digitized by Google

working meter adjusted for a mean pressure of 115 volts, and suitable for a house in which the minimum number of watts being taken at any time is 4,000. Special importance will be attached to the minimum load at which the meter can register correctly, and to the energy absorbed by the meter when the consumer is using a light load, or when no energy is being taken. Conditions of the competition were discussed and adjusted, and it was agreed that the award should be made during the session of 1896, the Society reserving right to withhold the prize in the event of there being nothing deserving the award. Alternatively, the Society may award a smaller amount should anything meritorious, but not deserving the full prize, be sent in.

The Overhead Conductor of the Baltimore Belt Line Tunnel.—The conductor of this line, which came into operation a short time ago, is simply a reversed iron conduit or trough erected overhead on trusses in the open and in the tunnel attached to the crown of the arch. In the open the conductor is directly over the centre of the track; in the tunnel over the centre line of the space between the tracks. The conductor consists of two 3-inch iron Z bars three-eighths of an inch thick, riveted to a cover plate, and is constructed in sections 30ft. long. It weighs about 30 pounds per foot. The height of the conductors above the level of the top of the rails is 17ft. 6in. in the tunnel. Outside the tunnel the height of the conductors above the rails is increased to 22ft. The supporting structure in the open consists of longitudinal catenaries of two chains of iron rods, having a span of 150ft., suspended from transverse trusses, supported by columns of latticed steel channels erected on either side of the double track. From the joints in the catenaries vertical rods are dropped at intervals of 15ft. to support the electrical conductors. Upon the straight track the conductors are suspended from single catenaries, while upon the curves a double catenary is employed.

Electric Lighting Provisional Orders.—In the Report, dated June 25th, made to Parliament by the Board of Trade respecting applications for and grants of Electric Lighting Provisional Orders since last summer, it is stated that in all 29 applications came before the Board of Trade, 14 being from Local Authorities and 15 from companies; 23 of these have been granted as follows:—Alderley Edge (L. A.), Bootle (L. A.), Carlisle (L. A), Leigh (L. A.), Liverpool (Co.), Llandudno (L. A.), Luton (L. A.). LONDON: Notting Hill (Co.), St. Olave (Co.), Strand (Co.), Motherwell (L. A.), Pontypool (Co.), Prescot (Co.), Radcliffe (L. A.), Salisbury (Co.), Southampton (Co.), Stirling (L. A.), Swindon (L. A.), Walthamstow (L. A.), Winchester (L. A.), Windermere (Co.), Windsor (L. A.), Worthing (L. A.). The total number of Provisional Orders in existence in the United Kingdom now amounts to 210, of which no less than 142, or 67 per cent., are held by Local Authorities. The total number of electric light undertakings actually at work or in progress amounts to 112. It must be remembered in this connection that one single undertaking has in some instances more than one Order. The Metropolitan Electric Supply Company, for instance, possesses three, covering Mid-London, West London and Paddington respectively. There are only seven Orders dating from 1883 still operative, and these relate to Bradford, Brighton, Bristol, Nelson, Richmond, St. Pancras, and Greenock, all of which, with the exception of the last, have been made use of. None of the 23 Orders granted this year have as yet received Royal Assent.

Telegraphic Communication with Fastnet Lighthouse.—The Fastnet Lighthouse has been placed in electric communication with the mainland. Some 10 years ago an attempt was made to place the Fastnet in electrical communication with the shore, but the cable would not stand the wash against the rocks. Taught by experience, the Royal Commission appointed to inquire into the matter of telegraphic communication between our outlying lighthouses and the shore decided to try the discontinuous cable method introduced by the late Mr. Willoughby Smith, and modified by his son, Mr. Willoughby S. Smith, and Mr. W. P. Granville. The laying of the cable was undertaken by the Post Office authorities, and the Telegraph Construction and Maintenance Company undertook the electrical arrangements. H.M. telegraph steamer "Monarch" arrived at Crookhaven on the 16th inst. On the 18th Mr. Lumsden, chief of the cable-laying department of the Post Office, made an early start, and before the day was out the cable was laid. Immediately all was completed Mr. W. Granville landed on the rock, and made the necessary electrical arrangements. The conductor of the cable ends in a heavy copper "mushroom" 30 or 40 fathoms from the rock, and a bare copper wire attached to an earth plate dips into the sea on one side of the rock, while the lightning protector makes earth on the other. Telegraph communication was soon opened up, many messages being sent to and fro between the Fastnet and the mainland. The apparatus on the rock is only temporary, and it will be two or three weeks before the permanent work there is completed.

The Incandescent Gas Burner and Street Vibration.—Referring to the use of the Welsbach light for street purposes, the *Gas World* remarks in a recent issue that "The general opinion among Continental engineers appears to be that while the gas consumption is lessened the cost of renewing mantles more than counterbalances the saving in gas: they admit the better light but recognise no monetary advantage. This may be quite true; and if it is, then what has to be done to make the Welsbach an economical street illuminator is to insure a longer life for the mantles. This might be done in two ways—either by making the mantle less fragile than it is at present, or by introducing some contrivance that would protect it from the vibration inseparable from our public streets; or it may be that the end may be attained partly in the one way and partly in the other. A few weeks ago we briefly described a contrivance introduced by the Incandescent Gas Light Company with the object of protecting the mantle from vibration, the device consisting of carrying the mantle gallery upon three springs. That device, as we then showed, had given very promising results, reducing the mantle breakages by 90 per cent. But even after that great reduction the breakages in the particular case referred to were very heavy, amounting, as our correspondent, 'A Northern Subscriber,' pointed out last week, to almost 29 mantles per annum. To renew a mantle 29 times in the course of a year would, it need hardly be said, be a very heavy burden upon the system. This week we have seen another vibration-absorbing device which promises to give still better results."

Niagara.—"While the Niagara power plant has not yet entered into commercial operation, the tests thus far made have," says the *Electrical World*, "demonstrated its entire success, and the engineers who have had part in this magnificent achievement may well be gratified at the result. . . . One of the most interesting sights to visitors at Niagara who descended into the pit was that of the 38in. vertical shaft tube, with its short 11in. solid sections at bearings, the whole having little indeed in common with the usual idea of shafting. While much admired by the electrical engineers inspecting it, the paradox of this mechanical transmission forming part of an electrical transmission plant was frequently referred to, and we are inclined to believe that few were satisfied with the reasons offered as to why the generators were located at the top of the pit instead of at the bottom. That the shafting is an element of weakness would be true if merely the questions of bearings and complication entailed were considered, but, in addition, there must be added the influence of the vibrations due to the water impact on the turbine blades. Here marine practice, with its almost uniform torque, does not apply, and the deafening sound in the pit due to the effect referred to left a disturbing thought in the minds of many. It was naturally in the generator that most interest was shown, and there was a noticeable indication of the professional pride felt by the visiting electrical engineers when they viewed this finest example yet furnished of the capabilities of their art. For their benefit loads were varied and thrown on and off, and once during the meeting a load of 5,300 H.P. was carried, the machine always running without a tremor, and with an appearance of ease, and even grace, that speaks highly for the design of its mechanical features."

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(Continued from page 395.)

49. Clark's Fall of Potential Test.—This test for the localisation of faults making partial earth has long been known, but hitherto has not been much relied upon owing to the impracticability of measuring potentials accurately on board ship by the usual methods.

There are three measurements of potential to be made, two at one end and one at the other. As the usual methods involved reading deflections or throws, it was customary to make the single measurement on board and the other two on shore, where they could be made with greater convenience and exactness. Now, however, null methods have been devised for all three measurements, and they can be made as easily on shipboard as on shore, and very accurately. Consequently the test can be reversed, either end freeing in turn and taking the single potential while the other takes the two potentials. This test is therefore brought in line with those most useful in localising partial earth faults, and it will probably be found of special use in difficult high-resistance faults.

The theory and connections of the Clark test may be briefly stated as follows. A battery and known resistance R (Fig. 150) are connected to the end A of a cable the other end B of which is freed. The potential at P falls proportionately to p at the junction of the resistance and cable and to p_1 at the fault C. The fall from this point to zero potential takes place over the

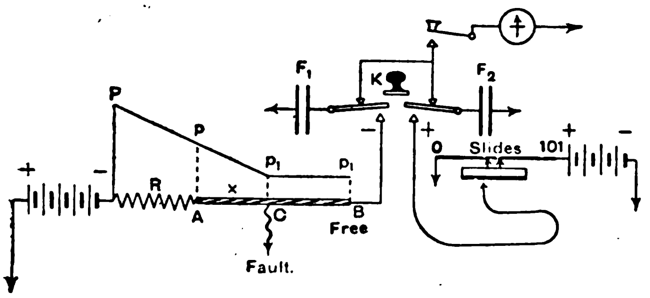

Fig. 150.

resistance of the fault itself and the return circuit, but there is no fall over the remaining part C B of the cable, because the end at B is free. The potentials P and p are measured at one end and p_1 at the other. We then have, by Ohm's law,

$$\frac{x}{R} = \frac{p - p_1}{P - p},$$

whence the resistance (x) from A to C is equal to

$$R\,\frac{p - p_1}{P - p} \text{ ohms.}$$

Mr. J. Rymer-Jones has devised a convenient method for the single potential reading (p_1) on board ship (described in the *Electrical Review* of September 7th, 1894). This is an ingenious adaptation of the mixed-charge test, and admits of great accuracy. Two standard condensers are connected as shown in Fig. 150 to the mixing key (either Lambert's or Silvertown pattern, described above), the lower contacts of which are in connection with the free end of the cable and the travelling contact of the slides respectively.

At the shore end the testing battery is connected up (zinc to line) through the resistance R for a pre-arranged number of minutes. This makes the potential p_1 negative. The battery on the slides is connected copper to slides and zinc to earth, thus giving a positive potential to the travelling contact. The charges given simultaneously to condensers F_1 and F_2 (on pressing down K and closing the charging keys) are, therefore, of opposite sign. If, now, the condensers are of equal capacity, and there is no deflection on the galvanometer after K has been raised and the charges mixed, it follows that they have both been charged to the same potential, or in other words that the potential on the slides at the travelling contact is equal to the potential at the end of the cable. Should the capacities F_1 and F_2 of the condensers not be exactly equal, the slide reading (after balance is obtained on the galvanometer) must be multiplied by the ratio

$$\frac{F_2}{F_1}.$$

We have, therefore, the potential p_1 expressed as a slide reading. The potential measurements at both ends must be reduced to the same units, and the simplest way to do this is to express them in volts. For this purpose, so far as the slide reading taken on the ship is concerned, it is only necessary to calibrate the slides with a standard cell in the manner described in the last paragraph. For example, say the slide reading is 950 divisions with a standard cell of 1·45 volts, and the reading obtained with potential p_1 is 3,603. The potential p_1 is then

$$\frac{1{\cdot}45}{950} \times 3{,}603 = 5{\cdot}5 \text{ volts.}$$

As regards the shore measurements, if these are taken by the method of charging a condenser and observing the discharge throws on the galvanometer, the actual value in volts can be determined directly by comparison with the throw produced by a standard cell with the same condenser and galvanometer. The E.M.F. of the standard cells used must be corrected for temperature, but no correction is required for

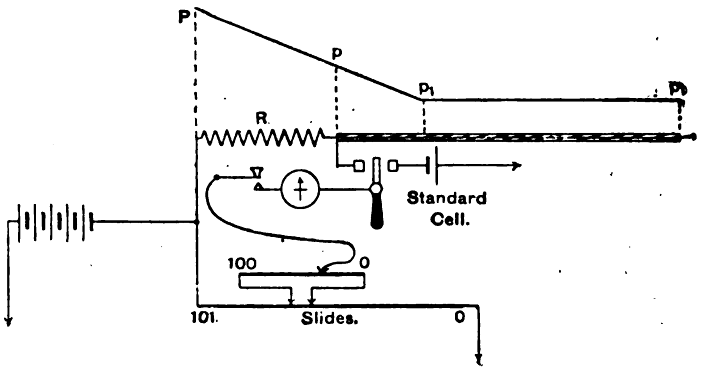

Fig. 151.

any difference in the E.M.F. of the standard cells used on the ship and on shore, as the measurements at both ends are absolute, and therefore entirely independent.

In the ordinary course the shore informs the ship of the added resistance in ohms and the two potentials in volts, and the ship works out the distance of the fault from the shore by the formula given above. When condenser throws are taken on shore it is advisable to make the added resistance about the same as the resistance x of cable up to fault plus the resistance of the fault. This makes sufficient difference in the two throws to minimise any error in reading a few divisions out. The approximate values of x and the fault will in all probability be known from shore tests taken before ship cuts in, but in any case the first rough test will show if R is too large or too little for getting convenient throws.

In place of the condenser throw method for measuring the two potentials on shore the author has devised a simple null method with the slides, by which there are only two balances to zero to be obtained in place of three condenser discharges. The slides are connected as shown in Fig. 151, and are balanced to zero by the potential p. By means of the two-way switch shown the standard cell is then put in circuit with the galvanometer, and a balance obtained by means of which the slides are calibrated. For example, say the slide reading is 816 with a standard cell of 1·42 volts, and 7,180 divisions with the potential p. This potential is then equivalent to

$$\frac{1{\cdot}42}{816} \times 7{,}180 = 12{\cdot}5 \text{ volts.}$$

The potential P is proportional to the total number of divisions to the slides, and therefore no observation of this is necessary. The number of volts per division, multiplied by

* Copyright. All rights reserved.

Digitized by Google

the total number of divisions, gives at once this potential in volts as follows :—

$$\frac{1 \cdot 42}{816} \times 10{,}000 = 17 \cdot 4 \text{ volts.}$$

The measurements taken are now

By ship $p_1 = 5 \cdot 5$ volts.
By shore $P = 17 \cdot 4$ „
and $p = 12 \cdot 5$ „

$$p - p_1 = 7$$
$$P - p = 4 \cdot 9$$
$$R = 350$$

Distance of fault $= 350 \times \frac{7}{4 \cdot 9} = 500$ ohms.

Standard cells of different E.M.F. have been taken as instances in the above example to show that no correction has to be applied in consequence of ship using a standard cell of different E.M.F. to that used by shore.

We have, therefore, *null* methods throughout for this test. The single potential measured on board is a balance to zero on the slides according to the adaptation of the mixed-charge method by Mr. Rymer-Jones as above referred to, and the two potentials measured on shore are also taken by balances to zero on the slides. These facilities make the test a very convenient and easy one to make, and for this reason capable of considerable accuracy.

Again, the readings being all by balances to zero, the test can be easily reversed—that is, the ship can add the resistance to the cable and measure the two potentials in the manner just described, the shore measuring the single potential at the other end. Again, the shore potential can be measured by the mixed-charge method given above; but, as the conditions on shore are favourable for getting a good condenser discharge throw, it would probably be found more convenient to measure the potential in that way by comparison with a standard cell.

It will be seen that the slides are connected up exactly as in a bridge test, and when the balance is obtained with the potential p the ratio

$$\frac{R s}{10{,}000 - s}$$

gives the resistance of cable up to fault plus the fault, s being slide reading at balance. It is useful to bear this in mind, as the resistance of the fault (always a desirable item to be placed on record, although not necessary in this test for localising its position) can be afterwards obtained by deducting its distance in ohms, as obtained by the potential method, from the above result calculated from the slide reading, considered as a bridge balance.

In this case the resistance of cable up to fault plus fault is

$$\frac{350 \times 7{,}180}{10{,}000 - 7{,}180} = 891 \text{ ohms.}$$

Deducting the cable resistance to fault above determined, viz., 500 ohms, we have 391 ohms as the resistance of the fault The same result is also obtained from the potential readings By Ohm's law the potential p_1 in volts divided by the current in amperes gives the resistance of the fault. The current is

$$\frac{P - p}{R} \text{ amperes,}$$

therefore the resistance of fault is equal to

$$R \frac{p_1}{P - p} \text{ ohms,}$$

that is, $350 \times \frac{5 \cdot 5}{17 \cdot 4 - 12 \cdot 5} = 392$ ohms.

In the fall of potential test described the resistance of the fault is neatly eliminated, but the potentials observed will be affected by the variation in resistance of the fault. For this reason it is better for shore to put zinc to line as stated above, so as to lessen the probability of the fault sealing up. If the fault resistance increases the potentials will all increase, and *vice versâ*, the variation being shown most on the smaller potentials p_1 and p, but very little on the larger one P. It is advisable therefore that the slide reading on board (p_1) and the throw (or balance) equivalent to p (taken on shore) should be repeated until the results are steady and reliable.

(To be continued.)

HIGH-SPEED CABLE SIGNALLING.

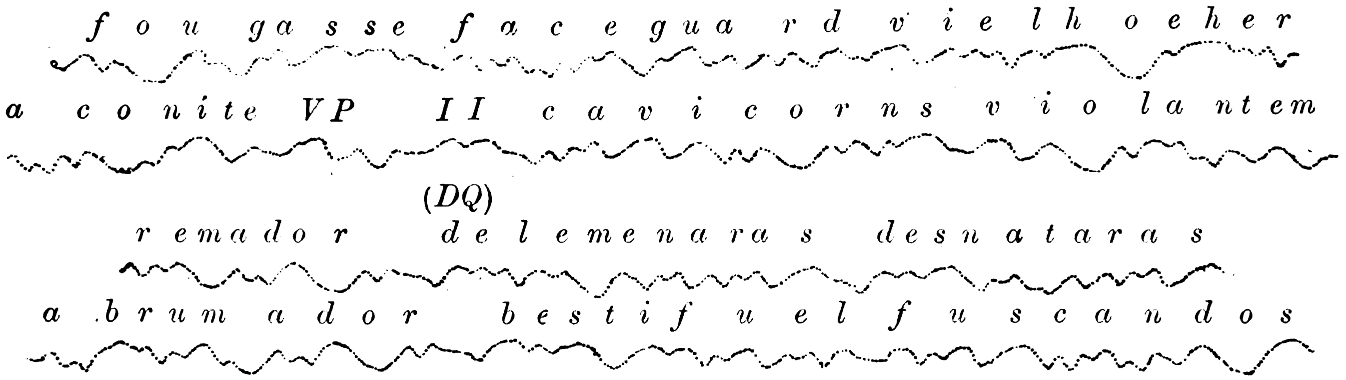
BY PATRICK B. DELANY.

In a Note on Cable Signalling which appeared in *The Electrician* of November 30, 1894, I gave the speed attained with regular traffic by my system of automatic transmission over the Anglo-American cables. These figures were not correct, as they were based upon an erroneous computation of spaces used between words by the Anglo-American Company. As stated in the article, *three* spaces are employed, and that number should have been reckoned in arriving at the speed for each cable; but only two were taken into account, therefore the speeds should read as in the following table.

It should be remembered that in this instance spaces are credited to words of *seven* letters, not five, as is usual in computing speeds; and furthermore, that these speeds were carefully checked at Valentia and Heart's Content by officials of the Company.

Cable.	Letters per Minute.
1873	153
1874	153
1880	133
1894	251

In an editorial comment on the article at the time you stated that it would have been more interesting had I supplied



Delany Transmitter. 1894 Anglo-American Cable. September 16, 1894. 247 letters per minute.

Digitized by Google

facsimiles of the signals at these high speeds. Absence from the country has prevented earlier response to that suggestion, and even now I am unable to supply facsimiles of these highest speeds, they having been reached with regular traffic; and as the Company paste the strip on forms instead of translating and copying, none of that strip is available. I submit, however, facsimiles of Code messages sent experimentally on Sunday, September 16, 1894, over the 1894 cable at a speed of 247 letters per minute according to careful official timing at both ends of the cable.

The speed of 251 letters with regular traffic on September 26th was maintained for half an hour constant working.

MUIRHEAD IMPROVED FORM OF SIPHON RECORDER.

The component parts of Dr. Alexander Muirhead's improved Siphon Recorder are so arranged that the various adjustments of it can be considerably more readily effected than hitherto, and the signal coil and other working parts of the instrument can be more readily removed in case of accident, damage, or when otherwise required. The magnet, between the poles of which the rectangular signal coil moves, is built up of a number of flat horseshoe-shaped permanent magnets of a special quality of steel, and is provided with adjustable pole-pieces. The signal coil is suspended by fibres, and is mounted, together with a fixed soft-iron core, on a brass plate affixed to a rack with which a pinion operated by a milled head screw engages. On the brass plate there is an arm carrying the bridge wire or fibre which carries the aluminium siphon cradle. On this bridge is also mounted the electromagnet forming part of the "vibrator" arrangement, to its hinged armature one end of the stretched wire carrying the siphon is fastened. On the left side of the framework of the instrument (*see* Fig. 1) are placed the interruptor of the vibrator, a set of slide resistances for the purpose of regulating the strength of the current flowing through the interruptor, and the small electromagnet in connection therewith. On the other side of the framework are placed the slide resistances for regulating the current flowing through the coils of the mousemill motor and the usual "receiving" shunts to the signal coil. In this instrument the ink box is also made adjustable, being carried by an arm attached to a pillar provided with a rack with which a pinion operated by a milled head screw engages. The motor is usually supported on a platform at the back of the instrument, and its driving wheel connected to the shaft of the paper roller by means of a spirally-wound steel band.

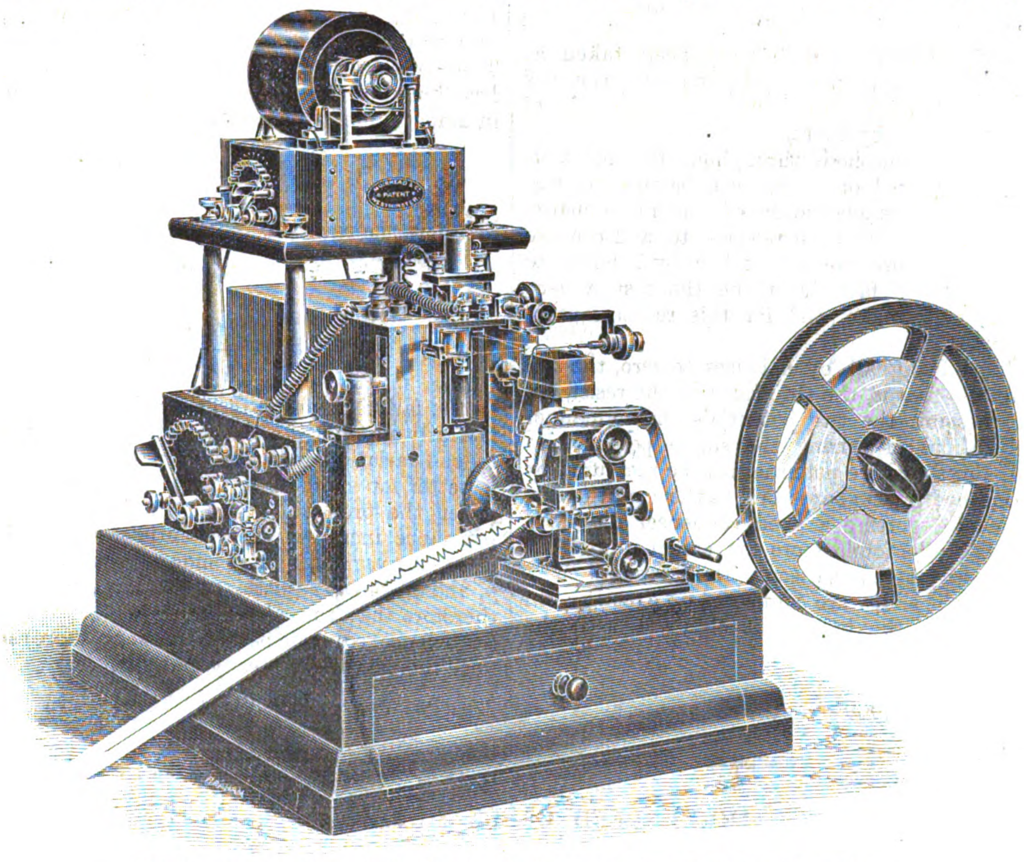


Fig. 1.—General View of Dr. Muirhead's Improved Form of Siphon Recorder.

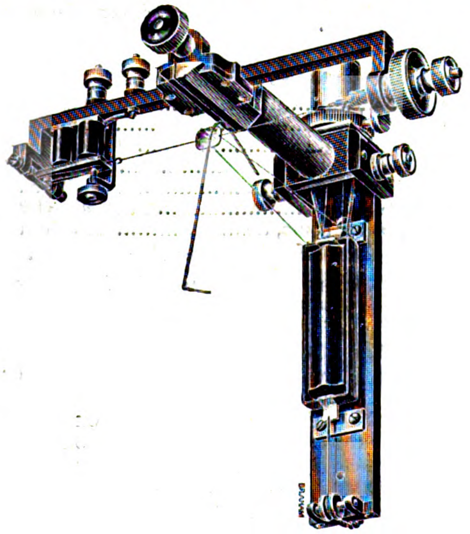

Fig. 2.—Details of Suspension of Dr. Muirhead's Improved Form of Siphon Recorder.

Perhaps the most novel feature of Dr. Muirhead's improved form of Siphon Recorder is in the suspension piece shown in Fig. 2, where it will be seen that the suspended coil is connected by means of two fibres attached at one end to a light arm fixed on the coil, and at the other end to the aluminium cradle to which the glass siphon is cemented. One of the

Digitized by Google

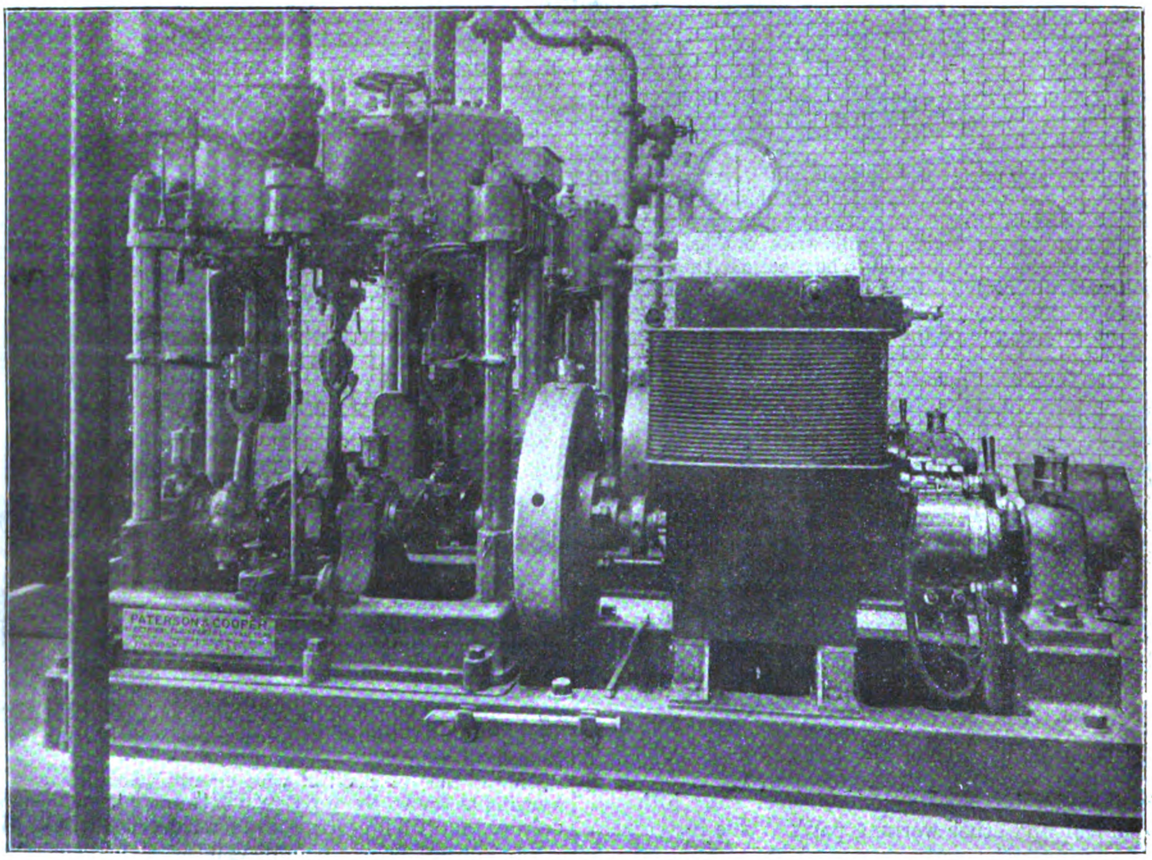
fibres is tied, or otherwise fastened, to a part of this aluminium cradle above the stretched wire or phosphor-bronze strip which carries the cradle, and the other fibre is similarly secured to a part of the cradle below each wire. The torsion of the stretched wire and the two fibres give directive force to the coil.

ELECTRIC LIGHTING OF GLASGOW HARBOUR TUNNEL.

The need for greater facilities of communication between the north and south sides of the Clyde at Glasgow Harbour has long been experienced, and various schemes have been proposed from time to time to meet the keenly-felt wants. It occurred to Messrs. Simpson and Wilson, a well-known Glasgow firm of civil engineers, who have had much experience in cutting underground railways, to accomplish the end desired by tunnelling under the river towards the lower end of the harbour, where the expected traffic, both foot and vehicular, would be greatest. A public company was formed to provide the necessary capital for the undertaking, and after the scheme had been thoroughly matured Parliamentary powers for carrying it out were obtained. That was in 1890. The work has now been finished, and the tunnel has been opened for public use. It should rather be said that the scheme embraces three tunnels—two for vehicular traffic and one for foot passengers.

Messrs. Simpson and Wilson's scheme has as its special feature two hoisting and lowering shafts, 76ft. in diameter and 75ft. deep, and in both cases they have been sunk within very short distances of the harbour walls. It was early resolved that the tunnels should be electrically lighted, as also the above-ground premises and the upper portions of the shafts. The engineers laid down the conditions on which electric lighting plans should be designed, and the offer that most satisfactorily commended itself to them was that of Messrs. Paterson and Cooper. One of the points which the engineers had in view in placing the contract for the lighting was that the installation should be of such a nature that the damp and moisture that would have to be contended with should do no damage to the leads, &c. The usual methods that have met with more or less success were suggested, such as lead-covered cables, cables in iron pipes, &c., but Messrs. Paterson and Cooper suggested the "Brookes" oil system.

The plant that has been installed and brought into use for doing the lighting of the three tunnels consists of three sets of direct-coupled engines and dynamos—two of them being equal to an output of about 20 kilowatts each, and the other a small auxiliary set of 6 kilowatts output. This plant is placed in the main engine house, which also contains the pumping and hoisting machinery, and is situated on the south side of the river. The two large sets of plant consist of inverted-type dynamos coupled on to compound engines of Messrs. G. H. Belliss and Co.'s make (*see* accompanying illustration). The Belliss central-valve engines have cylinders of 8½in. and 13in. diameter respectively, with stroke of 6in. They indicate 34 H.P., with a steam pressure of 95lb. The governor is fitted direct on to the crankshaft and controls the throttle, and is easily adjusted while the engine is running. A variation of less than two volts only is experienced between full and no load. Special precautions have been taken to ensure that the steam is dry, drip pipes being fitted directly above each engine, in addition to those on the main branches. The small dynamo is exactly similar in construction to the two large ones, and the engine which drives it is also of Belliss and Co.'s make, but is only a single-cylinder engine. Tachometers are fitted on each set.



Belliss Engine and Paterson & Cooper 20 kilowatt Dynamo.

The lights are distributed as follows:—

North shaft	10 arc lamps.
South shaft	10 arc lamps.
Foot Tunnel	50 32 c.p. lamps.
East Wheel Tunnel	25 32 c.p. lamps.
West Wheel Tunnel	25 32 c.p. lamps.
Engine room	2 arc lamps.
Pay boxes, boiler house, &c.	10 32 c.p. lamps.

Total—22 arc lamps, 110 32 c.p. incandescents.

The lamps are of Messrs. Paterson and Cooper's well-known "Phœnix" type, and are arranged to work two in series on the 110-volt circuit. The mains for the arc lamps in the north shaft are laid under the floor of the passenger tunnel in a 3in. iron pipe, filled with resin oil. The oil-insulated mains in both shafts run to a terminal box placed about 12ft. above the ground level on the side of the shaft. From the terminal boxes ordinary 600-megohm vulcanised rubber-covered cables, fixed on porcelain insulators, run to the various lamps. In the footway tunnel the 50 lamps are arranged along the centre line of the roof, the alternate lamps being on separate circuits. In the wheel tunnels the lamps are arranged alternately on either side, and in all the tunnels the lamps are enclosed in heavy enamelled cast-iron fittings with brass fronts and flint glasses, the whole being made water-tight by means of rubber washers. These fittings have special joint-boxes of malleable iron attached to them, through which the main pipes run, a specially packed gland being fitted close to the lamp-holder to keep back the resin oil. Special bends, fuse-boxes, &c., are

Digitized by Google

fitted to meet the requirements of the special form of insulation used.

It ought here to be mentioned that the tunnels are all 16ft. in internal diameter, and rather over 700ft. in length from shaft to shaft, and the shafts, like the tunnels, are quite circular in sectional area. The walls of the passenger tunnel are lined over a large portion of their surface by white enamelled tiles, so as to reflect as much light as possible upon the footway.

The electrical work was designed and carried out under the direct superintendence of Mr. E. George Tidd, A.M.Inst.C.E., Messrs. Paterson and Cooper's engineer and manager for Scotland.

MAGNETIC UNITS.

At the Oxford (1894) meeting of the British Association, Prof. Oliver Lodge, at the request of the Electrical Standards Committee, undertook to draft for future discussion a Paper on Magnetic Units. This Paper has been circulated among the members of this Committee, and with a view of obtaining opinions on this subject from those who are not members we have been desired to give space to Prof. Lodge's Paper in the columns of *The Electrician*.

Believing that the Committee is impressed with the convenience of affixing names to some of the more important units connected with the magnetic circuit, I beg to suggest the following considerations and recommendations, which I will write out as briefly as possible. The statements are intended to be precise in their terms; but in several cases alternative forms of definition are given.

1. That the unit coefficient of self-induction, though frequently useful, is by no means one of the most fundamental units, but should be defined in a suitably subordinate manner, with reference to other and more important quantities.

2. That it would be a mistake so to define it as to discourage the employment of the same term for as many other quantities of the same "dimensions" as possible; especially for the unit coefficient of mutual induction, and for unit "permeance."

3. That the essentially different quantities commonly called H and B should be carefully kept distinct, although their measures in air have been conventionally so arranged as to be numerically equal.

[*Summary of known facts and definitions.*—H being the intensity of magnetic force at a point, or the slope of magnetic potential (ω),

$$\omega_a - \omega_b = \int_a^b \mathrm{H}\,ds, \text{ along any length } ab;$$

and in a closed magnetic circuit the circuitation of H is equal to 4π times the total electric current through the area bounded by the magnetic circuit; or,

$$\text{cycle}\int \mathrm{H}\,ds = \text{circuitation of } \mathrm{H} = \iint 4\pi c\,d\mathrm{S} = 4\pi \mathrm{C},$$

or, at any point of space,

$$\text{curl } \mathrm{H} = \mathrm{V}\nabla\mathrm{H} = 4\pi c,$$

where c is current density.

If the electric circuit consists of n turns of wire threading the magnetic circuit, and each conveying the current C_1, then $\mathrm{C} = n\,\mathrm{C}_1$.]

First Quantity to be Named.

4. The first thing requiring a name is this quantity *magnetic potential*, sometimes called *magneto-motive force*, a quantity spoken of and measured, not inconveniently but with insufficient generality, by electrical engineers as ampere-turns. It has been proposed (by Mr. Heaviside, for instance) that it be called *gaussage*, and that its C.G.S. unit be one *gauss*.

5. The circuital gaussage round a closed curve is 4π times the total electric current through the area bounded by that curve.

In the case of a magnetic circuit wound with wire the gaussage is $1\frac{1}{4}$ times $\left(\frac{4\pi}{10} \text{ or } 1{\cdot}2566\right)$ the ampere-turns threading that circuit.

NOTE.—It *may* be best to retain the word "gaussage" for the whole of a closed circuit only, and to speak of the difference of magnetic potential between two points as the fall of gausses or the "gauss-fall" from a to b.

6. The gaussage, or gauss-fall, in any portion ab of a magnetic circuit, is measured by the change in the potential energy of a unit pole as it moves from a to b by any path which involves neither the cutting of magnetic layers nor the encircling of currents (a long channel being imagined for its motion through solid material if necessary). Or, more practically, it is measured by the induction through a long narrow tube whose ends are at a and b respectively, divided by the permeance of that tube. (*Cf.* Chattock on a magnetic potentiometer, *Phil. Mag.*, July, 1887).

In practice, however, gaussage is frequently calculable from the ampere-turns to which it is due.

7. Intensity of magnetic force, or H, will be naturally expressed as gauss-fall per centimetre, or the *gauss-gradient*. For instance, the earth's horizontal intensity at some place is 0·18 gauss per linear centimetre, or 5·4 gausses per foot.

NOTE.—H should not (strictly speaking) be expressed as so many lines per square centimetre; that mode of expression should be reserved for induction-density B. H is the cause, and should be thought of as the slope of magnetic potential, B is the effect. In a medium of so-called unit permeability the two quantities are numerically equal, but they should not be confounded; any more than the slope of electric potential, or electric-intensity (e), should be thought of as identical with current-density, even in a medium of unit conductivity.

8. The gauss-gradient inside a long or closed magnetic solenoid of length l, wound uniformly with n turns of wire each conveying the current C_1, is $4\pi n\,\mathrm{C}_1/l = 4\pi n_1\,\mathrm{C}_1$, where n_1 is the total number of turns of wire (in all the layers) to the linear centimetre.

This is the measure of H in the interior of such a solenoid, quite irrespective of the material with which it may happen to be filled.

Second Quantity to be Named.

9. The second quantity requiring a name is the *total induction* in a magnetic circuit, also called "total flux," "total lines," "electromagnetic momentum," and "electrotonic state." It is the quantity whose time-rate of variation gives the voltage induced in an electric circuit surrounding it once. It is proposed that its practical unit be called a "weber," and be defined as equal to 10^8 C.G.S. lines (or unit tubes) of induction.

(Denote the quantity for the present by N, and its density by B.)

[*Summary of Known Facts.*—e being the intensity of electric force, or the slope of electric potential, or the volt-gradient at a point; the circuitation of e = the induced E.M.F. in a closed circuit = the rate of change of induction through it;

or,
$$\text{cycle}\int e\,ds = \mathrm{E} = -\dot{\mathrm{N}} = -\iint \dot{\mathrm{B}}\,d\mathrm{S};$$

or, at any point of space,

$$\dot{\mathrm{B}} = -\text{curl } e = -\mathrm{V}\nabla e.$$

Through a simple closed electric circuit of constant resistance,

$$\mathrm{N} = -\int \mathrm{E}\,dt = \int \mathrm{R}\mathrm{C}\,dt = \mathrm{R}\mathrm{Q}.]$$

10. The total induction through any area may be practically measured by suddenly surrounding it with a closed wire circuit of n turns connecting the terminals of a ballistic galvanometer, and measuring the quantity of electricity thereby impelled through the galvanometer. The induction is equal to the quantity so impelled, divided by n times the resistance of the circuit. If the quantity is 1 coulomb, and the resistance 1 ohm, the induction is $1/n$th of a weber.

Or, otherwise, if the induction through any boundary changes at the rate of 1 weber per second, the E.M.F. excited in that boundary is 1 volt.

In the case of a spiral wire circuit through which induction is varying at the rate of a weber per second, 1 volt is excited *in each turn* of the wire.

11. *Another* mode of measuring the total induction through an area is to surround that area with a movable electric circuit of n turns of wire conveying a known current, and to measure the potential (or mechanical) energy of the circuit under those conditions. The induction is equal to the potential energy of the circuit divided by n times the current circulating in each turn of wire.

Or, if the induction through a simple circuit carrying 1 ampere is 1 weber, the potential energy of the circuit is 1 joule.

Derived Quantities.

12. Induction density, or B, may be expressed as so many webers per unit area—say per square centimetre or per square inch, or whatever is preferred for practical purposes.

For instance, the earth's horizontal induction density at some place is 0·18 C.G.S. unit $= 0{\cdot}18 \times 10^{8}$ weber per square centimetre = 18 microwebers per square metre.

13. The inductivity (μ), or absolute permeability of a medium at any point under specified circumstances, is the ratio of B to H at that point, and under those circumstances. In many substances this ratio is far from constant. [It may be expressed in terms of henries or other units of permeance per unit length (see below), instead of in C.G.S. units, if convenient. For example, the inductivity of air is $\frac{1}{100}$th of a microhenry per centimetre, or one millihenry per kilometre.] More explicitly it is measured by the webers per unit area divided by the gauss-fall per unit length; in other words, by the ratio of the weber-density to the gauss-gradient.

14. The relative inductivity of a substance as compared with that of empty space (μ/μ_0) may be called simply its "permeability" as at present, and is a mere number.

Digitized by Google

(Its electrical analogue is specific inductive capacity (K/K_0), as contrasted with absolute electric inductivity (K); which latter could be defined in practical units as the ratio of the coulombs displaced per unit area to the volt-gradient.)

Third Quantity to be Named.

The third quantity for whose unit a name is required is some form of ratio between the two fundamental quantities whose units are here named after Weber and Gauss respectively. It has been practically decided in America that this unit shall be named after Prof. Henry, of Washington, but the precise definition has not yet been agreed upon.

There are two quantities of the same physical dimensions to which the name is applicable, viz., the coefficient of self or mutual induction of a coil or coils of wire, and the permeance or inverse reluctance of a magnetic circuit.

The most logical order is to define permeance first, as the ratio of the webers of induction to the exciting gaussage, and then to say that the inductance of a coil of n turns of wire is n^2 or $4\pi n^2$ or $0{\cdot}4\pi n^2$ times the permeance of the magnetic circuit which it embraces, according to the units of gaussage and current which have been decided on.

If the units of gaussage and current are both the C.G.S. units, then $4\pi n^2$ is the numerical factor connecting inductance with permeance.

If the C.G.S. unit of gaussage is adopted along with the ampere current, then $0{\cdot}4\pi n^2$ is the factor.

But if the circulation of H due to *one ampere-turn* is adopted as the practical unit of gaussage, then n^2 is the factor; and the permeance of a cylinder, instead of being simply $\frac{\mu A}{l}$, is $\frac{4\pi\mu A}{10 l}$.

The apparent simplicity of this last system has much to recommend it for commercial use, though it will complicate the specification not only of permeance, but also of magnetic fields and potentials; but *some* inconvenience, due to the unfortunate definition of the unit pole, and the only less unfortunate definition of the practical unit of current, cannot be avoided; and our aim must be to place the inconvenience where least likely to be felt in everyday work.

First System.

We will begin with the more logical system, and with general statements which apply to both.

15. In a complete magnetic circuit the ratio of the total induction to the corresponding gaussage under specified conditions is called the "permeance" of that circuit under those conditions. It is not in general constant.

Or, the permeance of any solenoidal portion of a magnetic circuit, if free from intrinsic magnetomotive force or magnetic boundary layers, is the webers through it divided by the gausses between its ends.

16. The practical unit of permeance is that of a circuit in which a weber is excited by a gauss. Its reciprocal is the unit of reluctance. The practical unit so defined is 10^8 C.G.S. units.

Examples.—The permeance of a cubic metre of air to parallel induction from one face to the opposite is 1 microweber per gauss.

Under circumstances such that the permeability of iron is 400 times that of air, the permeance of an iron ring of one decimetre cross-section and 1 metre in mean diameter is $\frac{400\pi r^2}{2\pi R} = 20r =$ 100 C.G.S. = again 1 microweber per gauss.

It is, perhaps, a question whether this amount of permeance could be called a "microhenry" without confusion.

[*Explanation.*—The inductance (or self-induction coefficient) of an electric circuit consisting of n turns of wire, so far as it is constant, is defined to be equal to n times the induction produced through it by a current of 1 ampere in each turn. But the gaussage due to n ampere-turns is $\frac{4\pi n}{10}$ or $0{\cdot}4\pi n$; hence the inductance of a wire coil is $0{\cdot}4\pi n^2$ times the webers caused by each gauss in the magnetic circuit surrounded by it; *i.e.*, is $0{\cdot}4\pi n^2$ times the permeance of that circuit considered as constant.]

17. A coil of wire threading n times a complete magnetic circuit of unit permeance under any given circumstances is said to have $0{\cdot}4\pi n^2$ units of inductance under those circumstances; and in general the inductance of a coil of n turns is $0{\cdot}4\pi n^2$ times the permeance (as above defined) of the magnetic solenoid enclosed by it. (The permeance may here be considered variable.)

[With the ampere-turn as unit gaussage the $0{\cdot}4\pi$ is prefixed similarly to both inductance and permeance, so that only the factor n^2 is needed to convert one into the other. See below.]

18. The C.G.S. unit of inductance is equal to n times the induction excited through a coil per C.G.S. unit of current in every turn of wire; whereas the practical unit of inductance is n times the webers excited per ampere; hence the practical unit of inductance is 10^9 times the C.G.S. unit.

The practical unit is called a "henry." (It has also been called secohm and quadrant.)

Example.—If the above iron ring were wound closely with 1,000 turns of wire, the coil would have a coefficient of self-induction equal to $\frac{4\pi}{10}$ or $1\frac{1}{4}$ henries whenever the permeability of the iron was 400.

A coil of 20,000 turns of wire, wound closely on the same core, would have an inductance of $1\frac{1}{4}$ henries if it contained air or other non-magnetic substance.

Alternative Mode of Definition of Inductance on First System.

In view of one of the above practical methods of measuring induction experimentally, the inductance of coils of wire, both self and mutual, may be defined more directly thus:—

19. When of two simple circuits one conveys a current, the other in general has induction caused through it; and the ratio of the induction through either to the inducing current in the other is called the mutual inductance of the circuits.

20. Of two coils, with n and n' turns respectivel, the total mutual inductance is to be reckoned for every turn of wire on each coil, and is therefore $n n'$ times the inductance of the meant urn of one coil on the mean turn of the other.

21. The mutual inductance of two coils is $4\pi n n'$ times the permeance of the largest magnetic solenoid which threads both. For if every turn of one conveys a current C, while every turn of the other surrounds an induction N' in consequence, the permeance of the magnetic solenoid threading the second coil is $P = N'/4\pi n C$; but the total effective mutual induction, M C, through all the turns is $n' N'$; hence $M = 4\pi n n' P$.

22. When two coils each conveying one ampere are constantly connected by one henry of mutual inductance, the kinetic energy of the field due to their mutual action is one joule.

23. If the *self*-induction coefficient of a coil is being considered, its total inductance may be taken as n^2 times the inductance of the mean turn; that is n times the total induction through it divided by the inducing current. Or the weber-turns per ampere give the self-inductance in henries.

24. The practical unit of inductance, whether self or mutual, is called a henry; and a coil of n turns has a henry of inductance, on itself or on another of n' turns, when an ampere in one maintains $1/n'$ weber of induction (through itself or) through the other.

25. When the induction through a coil varies for any reason at the rate of one weber per second, the E.M.F. generated in each turn is one volt.

26. When the inductance of a coil is one henry, on itself or on another, a small variation of current in it at the rate of one ampere per second induces an E.M.F. of one volt in itself or in the other.

27. When the inductance of a coil conveying one ampere varies at the rate of a henry per second, the induced E.M.F. is one volt.

28. When the self-inductance of a coil is constantly, or on the average, one henry, while an ampere current is generated in it, the kinetic energy of the field due to that ampere is half a joule.

Second System.

29. If instead of taking a gauss as equal to a C.G.S. unit of magnetic potential, we take the circulation of H caused by one ampere-turn as the practical unit of magneto-motive force, we shall have 1 ampere-turn $= \frac{10}{4\pi}$ C.G.S. units of gaussage.

30. The practical unit of permeance will then be that in which a weber of total induction is excited by each ampere-turn; in other words, it will be $4\pi \times 10^7$ C.G.S. units of permeance.

31. And the practical unit of inductance will be that of a coil in which an ampere in every turn excites $\frac{1}{n}$th of a weber through every turn; that is to say, the inductance of a coil will be n^2 times the permeance of the magnetic circuit surrounded by it.

32. The difference between inductance and permeance is only one of reckoning. Permeance is webers per ampere-turn. Inductance is weber-turns per ampere.

Summary of the Advantages of this Sort of Mode of Defining Unit Inductance.

The special feature of this mode of defining the "henry" is that it makes inductance depend on the simple ratio N/C, or weber-turns per ampere, instead of on something more complicated.

It might possibly be defined as the ratio dN/dC, that is, as proportional to the tangent of the slope of the B : H curve; and such a definition would emphasise its variability; but certain practical advantages would be lacking, because it would be detached from any connection with the *permeance* of the circuit. The N/C ratio on the other hand instantly connects itself with permeance, and represents the slope of the secant drawn from the origin to any point of the B : H curve. It exhibits the variability sufficiently; making the inductance reach a maximum at the shoulder of the curve, and then slowly decrease as saturation sets in.

It is sometimes said—but the mode of expression is, to say the least, very inconvenient—that there are three different principles

Digitized by Google

on which to define L, all leading to a different result, viz., numbering them inversely but giving them in their usual order :—

(3) Energy .... $W = \frac{1}{2} L C^2$,
(2) E.M.F. .... $E = L\, dC/dt$,
(1) Total induction $N = LC$.

But the real facts to be expressed are not here exhibited. The real facts are

$$(1)\ N = LC,$$
$$(2)\ E = dN/dt,$$
$$(3)\ dW = C\, dN.$$

The essential thing to name is, therefore, N; and if 10^8 C.G.S. lines or unit tubes be called a "weber," or a "weber-turn," then a volt is a weber or a weber-turn per second, and a joule is a weber-ampere-turn. Nothing can be handier than that; and a henry can be defined as a weber-turn per ampere.

Instead of saying, as above, that there are three ways of defining L, the simplest thing is to say that two of the three equations as first given above are incorrect, except for the special and, in practice, comparatively rare cases when L is constant. Written out correctly they stand as follows :—

$$(1)\ N = LC,$$
$$(2)\ E = L\frac{dC}{dt} + C\frac{dL}{dt},$$
$$(3)\ W = \tfrac{1}{2} L C^2 + \tfrac{1}{2}\int_0^C C^2\, dL.$$

It is then obvious that (2) and (3) are too complicated to base a definition upon, and that the first alone gives a feasible system.

The fact that L is decidedly not in general constant deprives the henry of any such importance as the ohm possesses; moreover it refers explicitly to rather a special thing, viz., a coil of wire, and that under specified conditions if it contain iron; hence it would be rather absurd to name this alone of all magnetic units. In the above communication, in addition to a certain mode of defining the henry, it is urged that unit total induction be named too; for this is the quantity which is of real engineering importance—this is the quantity to attain which field-magnets are built, and in the midst of which armatures are spun.

It is also urged that it would be convenient if unit magnetic potential could likewise be named, since electrical engineers have shown that they have need of some such unit for the exciting cause of induction by their practical employment of the phrase "ampere-turns." The introduction of a gauss unit, in some form not too obviously limited to the case of a wire-wound coil, would assist teaching and would clarify magnetic ideas.

The present writer does not presume to decide between the two alternative systems of defining "the gauss" as given above: viz., the C.G.S. unit on the one hand, and the ampere-turn on the other.

APPENDIX I.

It need hardly be said that in the last resort it rests with practical men to employ or decline any suggested system of units. Those who daily deal with the quantities under consideration are the best judges of the utility or otherwise of a suggested unit, provided always that they take the trouble to give it a fair trial, and see how it works in practice. It may be hoped that the above or similar suggestions will meet with criticism at the hands of such men, and in order to make a beginning of criticism I asked the Departmental Lecturer on Electrotechnics at University College, Liverpool (Mr. F. G. Baily), to consider them with special reference to

(1) The large size of the weber and henry units;
(2) The handiest definition of the gauss; and
(3) The least troublesome mode of bringing in the 4π.

His reply, which is annexed, covers these points, and also incidentally refers to the quantity called I or intensity of magnetisation.

Now, as must often have been pointed out, the equation $B = H + 4\pi I$ is a barbarous one, involving as it does quantities of different dimensions in one equation. Its true meaning is, of course, $B = \mu_0 H + (\mu - \mu_0) H$; which, although algebraically only a roundabout method of writing $B = \mu H$, is yet convenient, as exhibiting separately the part of the induction due to the Ether and the part due to a material medium.

The customary convention of further denoting $(\mu - \mu_0)/\mu_0$ by the symbol $4\pi\kappa$ (or κ), and then christening κH as the magnetisation I, is likewise convenient. With this definition κ is a pure number, and I is a gauss-gradient or field-intensity. Another, but on the whole less satisfactory, definition, viz., the omission of μ_0 from the denominator, would make κ of the same dimension as μ, and I an induction-density.

The pull between two parallel magnetised surfaces of area A is $\frac{1}{2} A B H \div 4\pi$, that is to say, $N H / 8\pi$, and is therefore measured in webers multiplied by the gauss-gradient, or in joules per centimetre. But to maintain an induction density B in air requires a gauss-gradient B/μ_0, hence we might write the pull across an air-gap as $N^2 \div 8\pi\mu_0 A$. If the induction-density across an air-gap is expressed in microwebers per square centimetre the tension there comes out in units of which 2,500 would make an atmosphere; or, roughly, in pounds per square foot.

As for the strength of a magnetic pole—a quantity which, though fundamental in one sense, is seldom really dealt with—it will naturally be expressed in ergs per gauss, or in joules per gauss if it is very strong.

Mr. Baily's chief practical suggestions are first that a special unit of permeance, other than the henry, is desirable; and next that the $4\pi/10$ had best be thrown on to the μ, so as to keep the gauss equal to one ampere-turn. The fact that the inductivity of air will then cease to appear in its artificial garb of unity may even be regarded as a positive advantage, because its existence will then be less likely to be ignored. But I much fear that the ampere-turn as unit of gaussage, so near the C.G.S. unit in size and yet not equal to it, will be awkward and may lead to mistakes.

O. J. L.

University College, Liverpool, January 15, 1895.

Dear Professor Lodge,—In reference to the sizes of the magnetic units proposed by you, I find that the weber 10^8 C.G.S. would only be used in fractions. The largest dynamo that I know of has a magnetic flux, or, as you propose to call it, an induction of 0 5 weber. From this the value will go down to about 0·01 in small motors. These figures are, however, by no means inconvenient.

Transformers will be rather smaller. In these the weber-turn is a convenient size and an interesting quantity, as it is given by $\frac{1}{4}$ *of the mean volts per cycle*, or, more accurately expressed, *mean volts per unit frequency* ÷ 4. Its numerical value will lie between, say, $\frac{1}{4}$ and 50, according to the volts and the frequency; but it gives no indication of the size of the transformer.

The henry 10^9 C.G.S. is also large. The inductance of choking coils would in general be fractions of a henry. The inductance of the winding of a transformer has no very important meaning, but it has a convenient size. Measuring it as *mean volts per unit frequency ÷ four times the open circuit current in amperes*, the inductance of the primary coil on a 2 H.P. closed magnetic circuit 1,000-volt transformer would be about 40 henries.

The inductance of pairs of cables would run from 100 to 1,000 microhenries per kilometre, but the value would vary with the arrangement.

The induction per unit area is good; having a value in practical work from 1,000 to 20,000 C.G.S. units, it is given by 10 to 200 microwebers per sq. cm.

Gaussage would be about 50 in small transformers, up to 40,000 in large dynamos. The latter could be conveniently reckoned in kilogausses. To make the gauss = 1 ampere-turn appears to have great advantages in practice, and connects it directly with its usual source.

The idea of permeance is very useful, and the identification of its dimensions with those of inductance is neat. But I think it is liable to cause confusion, for the permeance of the core of a coil will be a different number of henries from the inductance of its wire. Moreover, the argument as to identical dimensions might equally be applied to the case of amperes and gausses. I would therefore have a new unit strictly connected with the henry, so that inductance $= n^2 \times$ permeance in a coil of n turns.

As to the units of permeance: with the above meanings of gauss and weber the permeance of a circuit would be $4\pi\mu A / 10\, l$, as you point out, instead of $\mu A / l$. But I wish to suggest a change in the method of reckoning, namely, still to retain the value of the permeance as $\frac{\text{webers}}{\text{gausses}}$, and permeability as $\frac{\text{webers per sq.cm.}}{\text{gausses per cm.}}$, therein giving up the convention of unit permeability of space, and giving it the value $1{\cdot}2566 \times 10^{-8}$ unit of permeance for a unit cube. In this way both the troublesome 10^{-8} and $4\pi/10$ are dealt with in an easily intelligible way. To avoid the high power of 10 it may be measured in micro-units of permeance, so that permeability of space and air = 0 012566 micro-unit of permeance for a unit cube, and permeability of soft iron = up to 25 micro-units for a unit cube. Thus we have permeance $= A\mu / l$, where μ is to be obtained from tables of its value, which can easily be altered to this method. Inductance then becomes $\frac{\text{weber-turns}}{\text{amperes}}$, or $n^2 \frac{\text{webers}}{\text{gausses}} = n^2$ permeance.

[Of course your phrase "weber-turns per ampere" means the same as the above webers ÷ amperes, and does not necessarily mean the weber-turns caused by *one* ampere.]

It may be objected that the C.G.S. units of strength of field, unit magnetic pole and intensity of magnetisation do not bear any simple relation to these practical units. This is chiefly important in the use of the magneto-metric measurement of iron, and in the measurement of the mechanical form of attraction between two magnetic surfaces in contact. But the expressions are not in reality much complicated; *e.g.*, present C.G.S. unit of intensity of magnetisation is given by $4\pi I = (\mu - \mu_s) H$, where μ = permeability of space = 1, and H = C.G.S. unit of magnetic force. This becomes $4\pi I = (\mu' - \mu'\ ) H'\ 10^8$, where H' is the gauss-gradient in the magnetic

Digitized by Google

substance, and $\mu'_s = 0{\cdot}012566$ micro-unit of permeance for a cubic centimetre.

As the single magnetic pole is unchanged, the force on it will be = strength of pole × gauss-gradient × 1·2566; but as this is not a calculation of frequent occurrence, except in magnetic surveys, the complication will not be serious. Other magnetic relationships are almost entirely of academic interest only, and would be carried out in C.G.S. units. Also the transition would present no difficulties to people with a little scientific knowledge.

I am of opinion also that as the legal volt has no direct connection with induction and velocity of motion, it is not necessary to define the practical units as they are defined absolutely. That is, ohm and ampere are the starting points, volt is obtained from them, weber from volt, gauss from ampere, permeance unit from weber and gauss, henry from weber and ampere or from permeance, and so on. This is much more easily explained to practical and unscientific men that the absolute derivations are, and it is the order in which they learn them.—Yours very truly,

FRANCIS G. BAILY.

APPENDIX II.

Another subject for discussion is whether L had better not be defined as dN/dC; with permeability as $\mu = dB/dH$ to correspond. This would make the three equations of page 7 stand thus:—

$$(1)\quad N = \int L\,dC,$$

$$(2)\quad E = L\dot{C},$$

$$(3)\quad W = C\dot{N}.$$

A letter just received from Mr. Heaviside indicates that he would probably favour this course, and there is evidently much to be said for it. I need hardly add that he contemns my temporising method of dealing with the 4π nuisance. O. J. L.

January 30, 1895.

According to the proposal of the Chicago Chamber of Delegates, the quantity which we call "inductance" and which is to be expressed in "henrys" is defined by the equation $E = L\,(dC)/(dt)$ for self-induction, or $E = M\,(dC)/(dt)$ for mutual induction, both being comprehended in one definition, the inductance L or M being calculated by dividing E in volts by $(dC)/(dt)$ in amperes per second. This implies that L or M is not to be defined as N/C, but as $(dN)/(dC)$.

I think names are desirable both for N/C and for $(dN)/(dC)$. I would suggest that the former be called "the total inductance" and the latter "the differential inductance." The distinction would be somewhat analogous to the distinction between the "mean specific heat from 0° to $t°$" and the "true specific heat at $t°$." Both total and differential inductance should be expressed in "henrys," for they are quantities of the same kind and when there is no iron, &c., in the field they are equal.

I think that the above mode of definition, involving as it does no magnitudes except current and time, is more readily comprehended than Dr. Lodge's proposed definition, in which the magnitudes involved are current, flux of induction, and the number of convolutions of the coil through which the flux passes. In the definition proposed by the Chicago Delegates, the consideration of the number of convolutions does not enter.

For a circuit or two circuits not having iron, &c., in the field, we may define inductance (in henrys) as the E.M.F. (in volts) due to variation of current at unit rate (one ampere per second). When the field is modified by the presence of magnetic material, the above will be the definition of "differential inductance."

The "total inductance" for any specified strength of current will be the mean value of differential inductance for equal increments of current from zero up to the specified strength.

I would suggest similar nomenclature in the case of permeability; $(dB)/(dH)$ should be called differential permeability, and B/H total permeability. In some respects "mean" or "average" would be a more correct designation than "total"; but these words would be liable to be misunderstood as referring to an average taken over the different parts of the body or circuit. "Total" is to be understood as standing for "calculated on totals."

As regards the magnitude of the unit of inductance, while I agree with Mr. Heaviside and Dr. Lodge that the unit pole ought to have been so defined that the mutual force between two poles is equal to their product divided by the surface of a sphere whose radius is their distance, a definition which would have made the line-integral of H due to a current C equal to C itself instead of to 4π C, I deprecate a mixing up of the two systems. So long as we employ our present unit of intensity of magnetic field, which results from our present definition of the unit pole, we cannot consistently reckon the line integral as equal to the ampere-turns. It must be reckoned as 4π times the ampere-turns, and the flux N must be reckoned as $4\pi\mu$ times the ampere-turns. The practical inconvenience of retaining the factor 4π cannot be considerable, for it is as easy to tabulate the values of $4\pi\mu$ as the values of μ.

Next as regards "permeance." I do not think it can conveniently be reckoned in henrys. I would rather reckon it in "webers per ampere-turn" which would be written "web. per amptu"; and there can be no possible doubt as to the meaning intended, when once we have fixed the magnitude of the "weber." There seems to be no difference of opinion as to what this magnitude should be. It is fixed by the relation $E = (dN)/(dt)$, E being in volts, N in webers and t in seconds. This is in accordance with Dr. Lodge's proposal, but Dr. Lodge has not explicitly recommended any name for the physical quantity which is measured in webers. Shall we call it "weberage"? It greatly needs a name; for "induction" may mean B instead of the surface integral of B, besides having many other meanings.

When permeance varies according to the strength of current, I would distinguish between "total permeance" N (n C) and "differential permeance" $\frac{1}{n}\frac{dN}{dC}$.

As regards "gaussage" and "gauss fall." I think the names will be convenient in the senses proposed by Dr. Lodge; but I cannot agree with his selection of a unit of measurement. The present definition of the unit pole (on which the present unit current is based) requires us to equate the line-integral in question to $4\pi n$C. To be consistent we must reckon "gaussage" as equal to 4π times the number of amptus. Dr. Lodge's proposal is to reckon C not in amperes but in C.G.S. units, thus introducing, as it appears to me, an awkward breach of continuity.

J. D. EVERETT.

THE OFFICIAL VOCABULARY OF CODE WORDS.*

The time which has elapsed since the publication of the Official Vocabulary of Code Words—compiled by the Berne International Telegraph Office, in accordance with the provisions of the regulations adopted by the Paris International Telegraph Convention—has permitted specialists to study and criticise it at leisure, and users of codes to give it a fair trial. It seems, therefore, desirable, under the present circumstances, and in view of the necessity of shortly taking action, to place before the readers of this *Journal*, and the commercial community at large, a record of the steps which the London Chamber of Commerce has taken in the matter, and a summary of the arguments and criticisms which have motived its opposition to the adoption of the Official Vocabulary in its present form.

In our January issue, when the official publication, which—unless the opposition to it is successful—is to become of compulsory use for all European code messages on January 1, 1898, was just being placed before the public, we took the opportunity of impressing upon our readers the importance of the change to the commercial community, and the necessity for users of codes to thoroughly test the new vocabulary for themselves, and not to take it upon trust. At the same time we invited communication of the results of those criticisms and tests. This article was followed almost immediately (January 28th), by the issue of a circular to members of the London Chamber, asking their opinion—

(*a*) As to the number of words in the vocabulary being sufficient or insufficient;

(*b*) The liability of error through too great similarity of words;

(*c*) the "delay" to be allowed before the compulsory application of the vocabulary.

As a result of the replies we received, and which not only expressed condemnation of the Official Vocabulary, but gave reasons for such condemnation, it was decided to approach foreign Chambers of Commerce, and to place before them certain objections to the vocabulary, in order to induce them to bring the matter under the notice of their respective Governments. The vocabulary being the result of an international understanding, no single Government can interfere with its application. It is only the authority which promulgated it, viz. the International Telegraph Conference, which can effect its postponement and order its revision—a course which, we may take it, will be followed only when the strongest case has been made out, and when sufficient pressure has been brought upon the constituent members of the Conference. With this object in view, a circular was issued to Foreign Chambers on March 25th last, in which, after a succinct statement of objections to the vocabulary, a request was made that the Chamber addressed should, either singly or in conjunction with other Chambers in the district, urge upon its Government the necessity of taking steps to procure the postponement of the date on which the vocabulary is to become obligatory, and a thorough revision, under competent direction, of the work of the Berne International Office. Replies were received from France,

* From the (London) *Chamber of Commerce Journal*.

Digitized by Google

Germany, Austria-Hungary, Italy, Spain, Belgium, and Holland. The majority of the Chambers replying stated that they were communicating or had communicated with their Postal authorities, in accordance with the suggestion made to them. Germany and Austria Hungary seem to have taken more interest in the matter than other countries; but one of the most important French Chambers—viz., that of Havre—not satisfied with urging upon the French Government objections to the use of the vocabulary in its present form, issued a strong circular to the French Chambers, recommending concerted action in the sense of the London representations.

The views of London merchants having been ascertained, and a large body of foreign opinion having been collected, it is the intention of the London Chamber of Commerce shortly to place these before the Chambers of Commerce of the United Kingdom, and, strengthened with their support, to bring before the Postmaster-General a statement of the objections and demands of the commercial community, not only of this country, but also of the larger part of the Continent, in regard to the publication of the Berne International Office. The circumstances, as our readers will see by the criticism of the vocabulary which follows, require that no time should be lost, and that Her Majesty's Government be asked forthwith to take the matter in hand, to make representations to the proper quarters, and at the next International Telegraph Conference—which we understand is to be held in Buda-Pesth in 1896—to support, and if necessary to propose, the postponement of the compulsory use of the vocabulary until competent revision and proper augmentation of that work.

A study of the vocabulary reveals to us the fact that, as we say in common language, the International Telegraph Conference has not got what it bargained for. In the preface of the book, the necessary requirements of such a work are stated to be as follows:—

"In order to establish a complete typographic and telegraphic dissimilarity between the words, each word ought to differ from every other word by at least two letters and by three elementary Morse signals. . . . A certain number of words were allowed to pass which differed only by two telegraphic signs, but these words differ sufficiently in their typographical characters, and the telegraphic resemblance is only obtained by an artificial grouping of Morse signs." The compilers therefore claim that, with the above exception, they have adhered to the rule which they themselves laid down and recognised to be necessary, whilst such is emphatically not the case. If they had kept the promise of their preface, there would be little fault to find with the vocabulary, beyond the fact that the number of words contained in it is too small for commercial requirements. But the present work is not only insufficient; it is, above all, an unsafe and dangerous work.

In this vocabulary, in which all the words ought to differ from one another "by at least two letters *and* by three elementary Morse signals," we find on a hurried and cursory examination:—

A. *One hundred and forty-two* words, every one of which is the *actual telegraphic equivalent* of another word, or is transmitted by *identical signals*.
B. *One hundred and twenty-two* words, every one of which differs from another word by only *one signal*, either a dot or a dash, the accidental omission, or the transmutation into the other, of that one signal turning the word into another word which in a code would bear a different meaning.
C. *Two hundred and twenty-two* words, every one of which differs from another by *one letter* only.
D. *One hundred and fifty-two* words differing from another by *the prefix* only.
E. *Eighty-eight* words having only *two letters* different.
F. *Ten printer's errors* and *misplacements*.
G. *Thirty-seven* names of *common articles*.
H. *Twenty-five* names of *days* and *months*.
K. *Six* telegraphic *service* words.
L. *Thirteen* names of *coins* and *measures*.
M. *Thirty-eight* names of *numbers*.
N. *Twenty-four* names of *places* and *districts*.
O. *One hundred and eight* names of English firms, and *Fifty-three* names of foreign firms.

A tabular statement of the above errors then follows, which, it is stated, must not be taken as exhaustive.

In fact we have already in hand evidence that the list can be greatly extended, and those of the members of the London Chamber who have used the vocabulary are sending in numerous instances of hopeless equivocation, and pointing out numerous mistakes which had escaped attention.

And let it not be said that these are purely technical objections, which would not interfere with the value of the vocabulary when in general use.

As a practical illustration of the defects of the vocabulary *when in use*, we will quote extracts from letters sent to the London Chamber by, among others, three prominent London firms:—

"We may mention," writes one, referring to experiments with words from the vocabulary, "that *in twenty-six telegrams* received or dispatched by us during a given period, no less than *forty errors* occurred in transmission."

"Our experience with it" (the vocabulary), writes another, "has been of so unsatisfactory a nature that we now wish to entirely withdraw even the qualified approval which we had previously given. *More than half the words* have arrived in a mutilated condition—some have even been incorrectly repeated—and as the vocabulary contains no 'terminational order,' it has been impossible to arrive at the meaning of some of the telegrams sent in until receipt of mail advices. We have consequently been obliged to remodel our code so as to conform to other and older vocabularies, compared with which the 'Official Vocabulary' is worse than useless."

"We have," writes a third, "been using for some months the new Official Vocabulary; we have practically tested it, and there can be no doubt that, in several respects, it is inferior to some of the word-collections which we have been using, notably 'Whitelaw's.' The latter is much more comprehensive, the words are better selected, and it has the great advantage of being provided with detectors which render the rectification of mutilated words easy and expeditious, while with the Official Vocabulary, in the absence of such detectors, such rectification is almost a hopeless task."

The compilers boast in their preface that they "have been entirely independent of pre-existing works of the same kind." From the result, we have no difficulty in believing this assertion. It only shows the unwisdom of disdaining experience.

But even if the compilers of the Official Vocabulary had kept their promise in regard to the character of the words used, there would still be ground for complaint against the compulsory adoption of that publication on account of its smallness. Whitelaw's code contains more than 300,000 words, and we doubt, as a result of long experience, whether the test suggested by the Berne compilers in their preface would result in the elimination of any considerable number. The Official Vocabulary contains a maximum of 256,000 words, and, as appears from the above examination, a very large number of them will have to be erased as unsafe for use.

The advantage of substituting compulsorily, at a time when international trade is increasing, and when code telegraphy is coming more and more extensively into use, a less complete and more faulty vocabulary for the altogether superior ones now in use is not exactly obvious. The International Telegraph Conference, we dare say, never intended such a result. It is necessary, therefore, that its attention should, at the earliest possible moment, be called to the exact facts of the case. The necessity of having a vocabulary containing as large a number of words as possible will now be greater than ever, since the liberty of invention, which had free scope before, will henceforward be effectively curtailed, and the commercial world will be strictly and compulsorily limited, in the compilation of their codes, to the actual words inserted in the Official Vocabulary, a very large number of which, as we have just shown, is altogether unsafe for use. After all, if the compilers of Whitelaw's code, whilst debarred from using geographical and proper names, have been able to arrange a code of over 300,000 words, coming up to the standard laid down by the Berne compilers, it is not very plain to us why the Berne compilers, with the help of such geographical names as Himalaya, Illyricum, &c., and of such proper names as Erasmus, &c., could not put together 256,000 words coming up to their own standard, unless we come to the sad conclusion that those experts were not as great experts in the art of vocabulary making as they might have been, and as the International Conference and the commercial world at large—considering that the result of their work would be its compulsory adoption—had a right to expect they should be.

We have said enough to show that the interests of European commerce demand a thorough revision of the Official Vocabulary before it becomes obligatory even for European telegraphy, and we trust that H.M. Government, when the question is brought before them, will not fail to pay heed to the results of commercial experience up to date, and will do their utmost to secure the postponement of the compulsory adoption of the vocabulary, and its revision at leisure under the direction of competent experts, who will not disdain experience, and will not make a point of being "independent of pre-existing works of the same kind."

Electric Transmission of Power in Egypt.—Certain American capitalists, says *Engineering*, associated with the General Electric Company, have taken steps to carry out Mr. Cope Whitehouse's plans for the development of electrical energy by water power in the North-East Fayoum. They have applied to the Egyptian Government, through the Department of State, to further their efforts, which aim at securing a concession for a trolley line from the Fayoum to Gizeh and Cairo, and the distribution of electric power for manufacturing purposes.

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to* **4** *p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is in preparation.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. 93 original illustrations, handsomely bound, price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

THE WORK OF HERTZ. By Dr. O. J. LODGE. Price 2s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c. By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. [*In preparation.*

THE PAST SESSION AT THE INSTITUTION OF ELECTRICAL ENGINEERS.

Whatever difference of opinion there may be as to the success of the past session of the Institution of Electrical Engineers, there can be no gainsaying the fact that it has been remarkable for the great variety of the subjects dealt with in the course of the sixteen meetings that were held between the beginning of November and the end of May. The first four Papers of the session related to electric traction. These were followed at the beginning of the year by a Presidential Address on electric supply problems, and by a Paper on the telephone switchboard. The extremely rare phenomenon of a telephone Paper, although due to a practical telephonist, was not, indeed, a product of the concentrated wisdom of the staff of the National Telephone Company; but it is possible that the next session of the Institution may bring forth a Paper which will confound the critics of this Company, and vindicate the scientific ability of those who have for so many years been in sole possession of the exchange work of the Kingdom. Following on Mr. KINGSBURY's welcome contribution to contemporary telephony came a Paper on dynamo design by Mr. W. B. SAYERS. Of the five remaining Papers, two of unusual interest and importance dealt with magnetism, one with the electrolysis of gold, one with the electric lighting of railway stations and goods yards, the last Paper of the session being Mr. MARK ROBINSON's much-discussed sketch of the constructional progress of the Willans engine. A session in which there were subjects of interest for electric traction men, telephonists, dynamo designers, transformer makers, electro-chemists, engine builders and users, and those practically engaged in the illumination of open spaces and large buildings, can scarcely be adjudged a failure

Digitized by Google

if tried by the "greatest happiness of the greatest number" test. Another noteworthy feature of the past session has been the advent of a large number of new speakers. The discussions at the Institution, it used to be said, were in the hands of a select few, and the man who really knew what he was talking about was unable to get in a word, even edgeways. That this was a fact cannot, we think, be disputed; but there is this much to be said in defence of those too frequent contributors to the Institution debates: without them there would in many instances have been no discussion at all, and if the remarks made did not add greatly to the store of floating knowledge, they rarely failed to be entertaining—no mean achievement in a gas-laden atmosphere and with no better material to work with than, let us say, the relative merits of half-a-dozen strictly similar rail bonds. The Papers and discussions of the 1894-95 session should in a measure also silence the complaint of those who thirst after practicality, but could in old days never get a sight of it on a Thursday evening at 25, Great George-street. For our own part, whilst fully admitting the need for a still more practical tone being given to the Institution debates, we trust that scientific theory, and those who expound it, may not be entirely banished to make room for buyers and sellers, contractors and manufacturers. Practical electrical engineering has benefited to an incalculable degree by the close union with scientific theory that has hitherto characterised it. We cannot too strongly combat the policy of those misguided separatists who are for ever urging the professor to stick to the lecture-room and the engineer to the workshop, with a view of bringing about that complete separation between these two factors of progress which so many engineers of the old school consider altogether natural and desirable.

An engineering journal, in a revolutionary moment, recently propounded the startling doctrine that the lecture was "an example of an absurd conservative adherence to an antique system." Emboldened by the example of our staid contemporary, we venture, not for the first time, to apply much the same language to the system of reading Papers, which still holds it own. The absurdity of the custom has been frequently exposed in these columns, and the Institution of Electrical Engineers might for once lead the way in so sensible a reform. Papers are presumably intended to be both understood and discussed. How can either end be attained by the authors getting up and running through their Papers with lightning-like rapidity and irritating inaudibility, and then sitting down with a satisfied sigh to await the comments of the audience, the majority of whom have never seen the Papers in print, and even the more favoured of whom have probably received them without diagrams and only a day or two before the date of reading? If it were a regular custom, as in all well-managed institutions it certainly should be, to send out proofs of all Papers complete with diagrams a week or ten days before the meeting, that perfunctory performance of reading the entire lucubration becomes mere wanton waste of time. If, on the other hand, the audience is left to gather what it can concerning the Paper from its *viva voce* delivery, then every care should be taken to ensure that the Paper is read in a suitable manner; an end that is best attained by entrusting the task of reading to some official accustomed to the work.

A final suggestion and we have done. We have of late had frequent occasion to bring to the notice of our readers the advance which is being made in electro-chemistry, both on the Continent and in the United States, and to regret that a subject, day by day becoming of more and more industrial importance, should find so little encouragement in this country. In the last session of the Institution of Electrical Engineers there was indeed one electrolytic Paper read, and this led to a discussion which should encourage those responsible to see that this branch of applied electricity is still better represented in the future. Both in Germany and in the United States special societies for the reading and discussion of Papers dealing with electro-chemical subjects have been formed. The formation of specialist societies is not, however, to be encouraged; more good will accrue from the fuller development of existing institutions. At present those engaged in electro-chemical work range from men on the one hand who are very well qualified as electrical engineers, but who have small knowledge of chemistry, to men who are well-trained chemists, but whose electrical knowledge is weak. Both these classes would benefit by mixing more with each other and interchanging views. There is also a large number of electrical engineers and of chemists who take an interest in electro-chemical questions, though not actually themselves engaged in any electro-chemical industry. In these circumstances there is, it seems to us, more to be gained by a greater freedom of intercourse between electrical engineers and chemists than by starting an Electro-Chemical Society, which would tend to the narrowness inseparable from specialism. The arrangements made by the Royal Society on the occasion of the reading of the Paper on "Argon" by Lord Rayleigh and Prof. Ramsay are an illustration of a course which might well be more frequently adopted. For instance, when an electrolytic Paper is to be brought before the Institution of Electrical Engineers, special notice of the date of the meeting might be sent to the Chemical Societies, and *vice versâ*. As it is, the secretaries of the various societies already send invitations to men belonging to other societies whom they are informed are interested in the subject down for discussion, but the invitation not being, as a rule, addressed to a society as a whole, only certain men get invited, and not always those who have most to gain by attendance. So far as the chemists are concerned, there is little difficulty, as there is only one electrical society, namely, the Institution of Electrical Engineers, to which the dates of meetings would have to be communicated; but when we come to arrangements between electrical engineers and chemists the case is different, for there is not only the Chemical Society, but also the Society of Chemical Industry and the Society of Public Analysts. However, as all these three societies are represented on the Council of the Institute of Chemistry, the notification to the chemical profession at large might, without much difficulty, be made through that body.

If the programme for the ensuing session of the Institution comprises a somewhat larger proportion of Papers dealing with electro-chemistry, together with a Paper or two on central station management, and perhaps one dealing in a broad philosophic manner with the design and manufacture of electrical measuring instruments, no important section of the electrical industry will have been neglected. An engineering society should, of course, exist for other purposes than the reading and printing of Papers and the origination of discussions. The initiation and carrying out of tests and trials, the results of which would be of the greatest value to the industry at large, though beyond the province of any individual member of it; the exercise of some degree of censorship over professional conduct, are matters well worth the attention of an institution which has been nearly a quarter of a century in existence and which represents a profession where the calling of consulting engineer's canvasser flourishes like the proverbial green-bay tree and where a perplexing variety of functions is too often performed by one and the same versatile individual.

REVIEWS.

Petroleum: Its Development and Uses. By R. Nelson Boyd. (London: Whittaker and Co. 1895.)

In this handy little brochure of some 85 pages the author has put together a considerable amount of interesting information, relative to the occurrence, commercial preparation and uses of petroleum. No attempt to compile a formal treatise or text-book has been made; but as text-books on petroleum, of a very voluminous nature, are following one another rapidly into the market, the author has probably not erred in making his book small and placing it within the reach of everyone. The author has something to say about most of the modern applications of petroleum; but he does not appear to have made himself as sure of some of his facts as might be desired, and there is a looseness or vagueness about much of his writing which is apt to leave the reader in doubt. For example, in referring to the use of petroleum refuse as liquid fuel, he says:

"Considering that liquid fuel, if properly consumed in a locomotive, does not emit either smoke or noxious vapours, it seems surprising that it has not been adopted on our underground railways. There might be some reason for this; perhaps the frequent stoppages may be supposed to interfere with the combustion, and yet one would think that any mechanical difficulties could be overcome. It is certain that if a smokeless fuel could be adopted in the tunnels of the underground railways instead of the sulphurous coke at present used, it would be a great comfort to the millions of passengers who travel by these lines."

Now, if the author had taken the trouble to ascertain the price of a ton of petroleum refuse on the underground locomotives, he would have seen at a glance why this fuel is not used; while if he had pushed his inquiries further, and investigated the apparatus employed on Russian and other oil-driven locomotives, he would not have suspected that the "frequent stoppages" would be more troublesome with oil fuel than with coal, nor that there were any mechanical difficulties yet to be overcome in this respect. It is not improbable that the market price of astatki will in time become considerably reduced, and in that happy future we may see, not only underground locomotives, but steam boilers of every class fired by this pliant and economical liquid fuel.

In a short but interesting chapter the author summarises the various theories of the origin of petroleum which have been advanced by experts. Mr. Boyd strongly inclines to the hypothesis of organic origin, a view which has received tremendous support in Dr. Engler's successful production of artificial petroleum by the distillation of animal fats and oils at a moderate temperature and under great pressure. A contemporary has recently stated that "a hundred thousand whales would be required to supply as much oil as Baku exports yearly"; but this does not by any means reduce the organic hypothesis to an absurdity; for, as Mr. Boyd shows, "oil is frequently found in strata devoid of any trace of past animal life; but it is well known that petroleum flows for long distances from the point of its production or storage in the earth." The products of many hundreds of square miles of natural manufacture may conceivably be collected and tapped under a very small area of actual petroleum field. Moreover, there is no need to hypothecate great whales, for there is or has been at some time an enormous amount of microscopic organic matter in sedimentary rock; a fact, which a careful examination of drift is sufficient to explain, or which is readily accounted for by the processes by which sedimentary rocks are formed.

We can recommend this little book to anyone who wishes to learn a few general facts about petroleum.

Extracts from the Private Letters of the late Sir William Fothergill Cooke, 1836-9, relating to the Invention and Development of the Electric Telegraph. Also a Memoir by Latimer Clark, Esq., F.R.S., Past President Institution E.E. Edited by F. H. Webb, Secretary. (E. and F. N. Spon, London and New York.)

The publication of these letters, previously accessible only in the library of the Institution of Electrical Engineers, will be welcomed by everybody interested in the early history of electric telegraphy, and perhaps hardly less so by the student of human nature as exemplified in the personalities of Messrs. Cooke and Wheatstone. The question as to the relative claims of these two inventors is pretty well settled by this correspondence, which of itself is a remarkable proof of Cooke's foresight and business capacity. The letters are addressed to his mother chiefly, while his experiments were in process, and describe with more or less circumstantiality the progress he makes in constructing a practical working electric signalling system; and this avowedly with the object of establishing the facts in writing, on paper bearing the date stamp impression of the post office, in case his claims to priority of invention should be subsequently challenged. But it by no means follows that we need attempt the apportionment of these respective claims; posterity will do that. Suffice it, that Cooke had the insight to perceive the enormous value of the invention, and the energy to push it into complete realisation. He had also the proverbial good luck which favours all capable men, and had barely shaped out his project before meeting with "a Mr. Wheatstone," who in a scientific way had been experimenting on similar lines. The relations of these two men are most interesting as illustrating the inevitable friction where high science and the practical mind come into close contact. It is instructive, also, to note that even Faraday shook his head over Cooke's grand schemes, and would say nothing to lead him to expend time and money on what might prove a profitless quest. But Wheatstone, besides being a chemist, was a mechanist of singular ingenuity, and whatever may be said as to his share in originating the electric telegraph his fame will ever be associated with the perfection of the appliances which have made it what it is to-day. It is curious, however, to note in these pages that the man who subsequently made one wire do the work of 10 or 15, was originally engaged in the problem of how to make almost as many wires answer a purpose which one would have served quite as well. In Cooke's and in Wheatstone's hands alike the invention was singularly immature at first. But the time was ripe; railways, then rapidly developing, greatly needed assistance of this kind; and perhaps the most remarkable feature about the telegraph is the short space of time it took to grow to maturity. All this is told in the brief pages which Mr. F. H. Webb has edited with admirable taste by permission of the Institution of which he is the secretary. An excellent portrait of Sir W. F. Cooke and some fac simile letters adorn the booklet; and a memoir by Mr. Latimer Clark, reprinted from the Institution *Journal*, fittingly completes a worthy memento of the origin of, perhaps, the greatest invention of the age.

Lehrbuch der Experimentalphysik. By Adolph Wüllner. Vol. I., General Physics and Acoustics. (Teubner, Leipzig. 12s.). Fifth Edition.

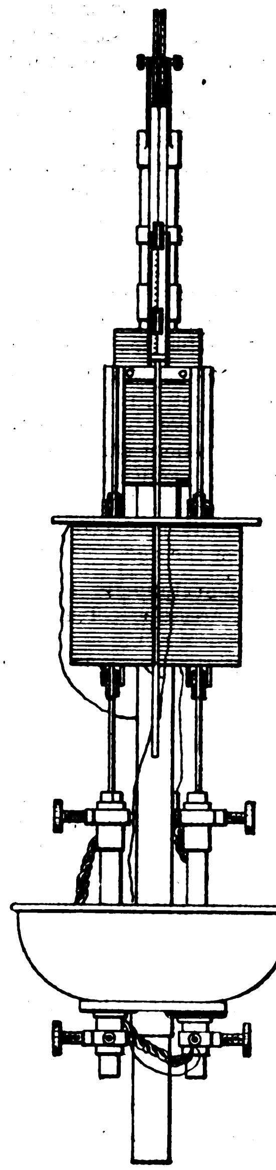
The first volume of the new edition of this well-known work is brought up to date as far as the end of 1892. As before, a few references are given in the text, and a summary of the literature is placed at the end of some of the most important sections. The peculiar, and for some readers the most valuable, feature of this work is that it introduces the higher mathematics into the discussion of physical problems where necessary, while an admirable introductory chapter on the chief theorems and operations of the calculus enables the reader to follow these discussions without the necessity of a close acquaintance with higher methods. At the same time, the book seems to take nothing for granted in the way of physical science, and the most elementary instruments and problems are effectively dealt with. The subject of the dimensions of physical quantities is just touched upon, and might have been treated a good deal more fully with advantage. In the chapter on the conservation of "work" the term "energy" should have been substituted, and the designation of $\frac{1}{2}mv^2$ as *vis viva* is rather more erroneous than antiquated. The chapter on the mechanical properties of solids is satisfactory, and under Friction we find Boltzmann's theory of the internal friction of solids fully dealt with. The same may be said of the chapter on Liquids, which includes such subjects as drops and surface tension, and is quite up to date. Considering the great progress recently made with mercurial air pumps, the section dealing with these is somewhat meagre, but allowance should be made for an *embarras de richesse* in this field, and the

Digitized by Google

chapters on diffusion and the kinetic theory of liquids afford some compensation. The section on wave motion is perhaps the best in the whole book, and forms a valuable introduction to the theory of sound, which makes up the second part of this volume. The beautiful experiments of Krigar-Menzel and Raps on the mode of vibration of bowed strings meet with the notice they deserve, and the curious phenomenon of the uniform velocity of the centre is brought out well by the photographic traces. Altogether, the subject of sound is about as fully dealt with as lovers of this rather neglected field of physics can well expect nowadays. Taking the volume as a whole, we may say that it is a good combination of high-class subject matter and excellent illustration. The binding is, as usual, faulty, but the print, in the Roman letters now almost universally adopted in German scientific books, leaves nothing to be desired.

THE GWYNNE DOUBLE-CARBON PHOTOGRAPHIC ARC LAMP.

We were afforded, a few days ago, an opportunity of inspecting a new double-carbon photographic arc lamp which is being put on

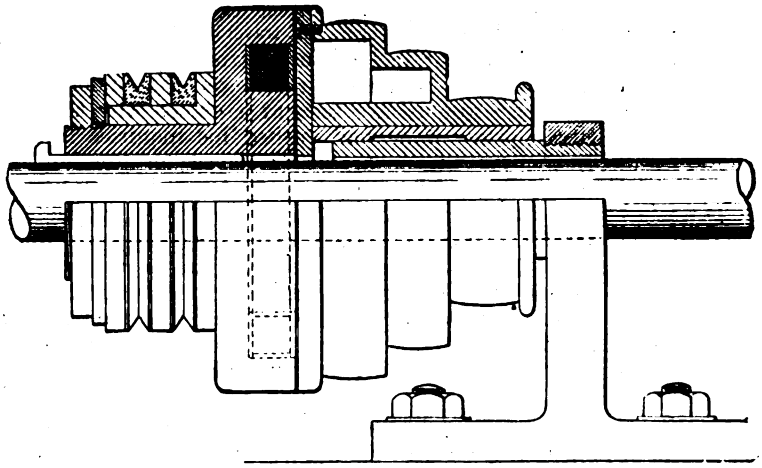


Gwynne Double-Carbon Photographic Arc Lamp.

the market by Messrs. Gwynne and Co., of Brook-street Works, Holborn. The great advantage of a double-carbon lamp over one with a single-carbon is the saving of current to the photographer, since for photographic purposes as good if not a better light is obtained with this arrangement with a total current of 25 amperes than with a single pair of carbons taking 50 amperes. Then, again, the roaring that accompanies a large current lamp when first switched on, is practically done away with. Photographers have also experienced considerable difficulty in getting so large a current as 50 amperes, and in many cases they have had to do without the electric light altogether, because the supply companies cannot have so large a current switched on and off upsetting the rest of their circuit. The accompanying illustration shows the working parts of this lamp.

THE HOLDEN MAGNETIC CLUTCH.

The accompanying illustration represents a magnetic clutch devised by Major Holden, and which has been found to be a great convenience at Woolwich Arsenal, where it has been tried practically for some time past. Now that the advantages of electrical transmission of power in workshops in place of heavy belting and gearing have been recognised, the field for magnetic clutches is likely to become a wide one, as the most economical results will probably be obtained from a motor of fair size driving a short line of countershaft from which the various machines are run. A clutch of the size represented is capable of transmitting at 350 revolutions 3 H.P. in regular work, the expenditure of electrical energy during the time that the clutch is in action being less than 20 watts. Simple forms of switch have been devised for starting and stopping, one form being similar to the arrangement in ordinary



Holden Magnetic Clutch.

use with fast and loose pulleys, where pulling one cord starts, and the other stops the machine, and another form which is actuated by one cord only, the switch being put on and off by alternate pulls of the cord. Messrs. Drake and Gorham are joint patentees with Major Holden.

LONDON COUNTY COUNCIL.

LOANS FOR MUNICIPAL ELECTRIC LIGHTING.

At the usual weekly meeting of the London County Council, held last Tuesday at the County Hall, Spring-gardens, Sir Arthur Arnold presiding, the Finance Committee reported that they had considered an application from the St. Pancras Vestry for a further loan of £75,000 for electric light purposes. As would be in the recollection of the Council, the Vestry had already established an electric light station in Stanhope-street, had laid mains in various streets, and had built battery sub-stations in High-street, Camden Town, and in Regent's Park-road. On those various works the Council had already advanced or sanctioned loans to the extent of £107,700, and the Vestry finding that the demand for electricity was increasing beyond the capacity of the Stanhope-street station, and also to assist in disposing of the parish refuse, now proposed to construct a combined electric lighting station and refuse destructor, for which the present loan was required. The Vestry had acquired certain premises in King's-road, Camden Town, for a central lighting station, for £8,592, and Bangor Wharf, in connection with the collection, removal and disposal of house and street refuse (to be used in connection with the electric station for £9,924.) The building and works were estimated to cost £27,201, and contracts had been entered into for about £25,000 of that amount. The cost of the necessary engines, dynamos, boilers, switchboards, mains, &c., was

Digitized by Google

estimated at £35,569, in respect of which contracts had already been entered into for £32,092. In addition to the electric lighting machinery there was an engine and boiler, two mortar mills, stone breaker, fans, and other appliances intended for use with the refuse destructor, in respect of which contracts had been taken for £1,100, making, with professional and other charges, a total of £34,760. The Vestry asked that the whole cost might be treated as a loan for electric lighting purposes, and spread over 42 years, but the Committee were of opinion that the cost in connection with the removal and disposal of the street and house refuse must be treated separately, and regard had to the life of that part of the outlay. As the Vestry did not require to take up the whole of the £75,000 at once, they considered that the loan should be limited to the amount at present required, viz., £56,100, and made subject to a restriction as to further borrowing to supply any necessary replacement of plant and machinery until the amount raised had been paid off, any plant requiring to be renewed in the interim being defrayed out of a sinking fund for renewals or from maintenance account. They accordingly made recommendations to this effect, which were agreed to.

The Committee also presented an urgency report, in which they stated that they had again had under consideration the application of the Vestry of Islington for a loan of £51,000 for the purposes of electric lighting. On January 22nd last they recommended the Council to sanction a loan of £18,000 towards the cost of erecting a central station at Eden-grove, Holloway, repayable in 50 years, and of £33,000 to provide the necessary plant and machinery, mains and pipes, repayable in 20 years. The consideration of the matter was adjourned by the Council from the 22nd to January the 29th, when the recommendation was withdrawn on the implied understanding that a further representation should be made to the Treasury with a view to obtaining an alteration in the periods to be allowed for repayment of loans for the initial cost of electric lighting installations. Their further correspondence with the Treasury having been communicated to the Vestry, the Committee informed them of their willingness to recommend the Council to sanction the borrowing of the £51,000 on the terms set out by the Treasury, either for 42 years for the whole amount, or divided into terms of 50 and 20 years. The Vestry replied that they were not prepared to accept the terms offered, and asked the Council to sanction the borrowing of the sum required, unconditionally, the loan to be repaid as provided by Section 190 of the Metropolis Management Act, 1855. In making that request it did not appear to the Committee that the Vestry had sufficiently recognised the fact that it was the duty of the Council not only to see that loans were required for the purposes authorised by the statute, but to safeguard the interest of future ratepayers by not allowing any burthen of debt to be placed on them which should be borne by the present occupiers. In offering the Islington Vestry the same terms as St. Pancras—who accepted them—the Committee thought they had gone as far as the Council could reasonably be asked to go in facilitating the borrowing of money, and therefore they could not advise the Council to give an unconditional sanction to the Vestry borrowing the £51,000. The Vestry had since reconsidered the matter, and now asked the Council to sanction the borrowing of the £51,000, and also to lend the money at £2. 17s. 6d. per cent., the loan to be repayable in 42 years on the annuity system. That request might now be complied with, subject to a restriction as to further borrowing to supply any necessary replacement to plant and machinery until the amount raised had been paid off.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *July 20, 1895.*

New Problems in Electric Traction.—That the transmission of several thousand amperes of current by means of a sliding contact trolley is not a simple matter has been demonstrated in the recent trials of the 96-ton electric locomotive at Baltimore. When the channel in which the sliding trolley shoe runs is clean, no particular trouble is experienced; but, unfortunately, the dampness of the tunnel causes rust to quickly gather, which in turn sets up "fireworks" of considerable magnitude upon the passage of the shoe. Several weeks ago this resulted in the shoe becoming red hot and wedged or welded into the channel while a heavy train was being moved, and now a cleaning arrangement run by an electric motor is employed to keep the contact surfaces clean. In some recent high-speed electric trials at Nantasket Beach, Mass., it was demonstrated that the ordinary trolley line is unsuited for such work. At high speeds the trolley wheel was thrown off in passing under trolley-hangers, and the flashes from the sparks kept up a continuous illumination above the car.

Electric Railway Law Suits.—In a few months the principal case relating to the invention of the trolley will come up for trial, and in view of a recent decision the outcome is a matter of some doubt, notwithstanding that numerous forms of trolleys had been patented years ago for transmitting telegraph currents to moving trains. In a patent suit decided several weeks ago the Court took the position that the inventor, whose patent for a combination of a trolley, trolley support and overhead turn-out switch was sustained, had accomplished by his labours the solution of the electric railway problem, and therefore should be treated in the most liberal spirit. As the judges who decide patent questions in United States courts are entirely ignorant of the technical matters entering, and many apparently cannot grasp the simplest technical ideas, they are very prone to raise general issues or adduce "broad principles," and upon these base their decisions. Unfortunately, they are as apt to go astray in this direction as in the other, as shown in a number of instances. In the feeder-and-main suit, for example, a learned judge established the principle that without Edison's discovery involved in the patent, incandescent lighting from central stations would have been impossible, and in the recent railway suit the judge was apparently of the opinion that, notwithstanding what he believed to be superhuman efforts on the part of inventors throughout the world, electric traction remained impossible until Van Depoele invented some trolley details and a turn-out switch. All of which goes to show the necessity of patent courts with judges competent to consider technical issues.

LEGAL INTELLIGENCE.

Wandsworth District Board of Works v. The County of London and Brush Provincial Electric Lighting Company (Limited).

Mr. Channell, Q.C., with whom was Mr. Chubb, applied to Mr. Justice Stirling, in the Chancery Division, on Tuesday last, on behalf of the plaintiffs in this case, that the defendants, their servants and agents, be restrained by order and injunction from "excavating or constructing or placing in or under any highway within the district of and vested in the plaintiffs' Board any transforming or converting stations, or other chambers or receptacles, for the purpose of containing transformers or other apparatus for the purpose of transforming or converting electrical energy at a high pressure to energy at a low pressure, and from constructing or placing in or under any such highway any other chambers or stations, not being street boxes authorised by Clause 12 of the Provisional Order granted by the Board of Trade in respect to Wandsworth, and scheduled to the Electric Light Orders Confirmation (No. 5) Act, 1892, and from using any boxes constructed by the defendants under the powers of the said Act for the purpose of transforming electrical energy as aforesaid or for any other purposes not authorised by the said Clause 12."

The learned COUNSEL stated that the question for his Lordship was whether what the defendants were proposing to do came within the powers conferred upon them by their Provisional Order. The matter turned really upon Section 12 of the Order. Under Section 11, the undertakers were bound to supply the electrical energy by a system approved by the Board of Trade, and subject to such regulations as the Board might make. By Section 12 the undertakers were authorised, subject to the provisions of the Order and the principal Act, and any regulations made under the Order, to "construct in any street such boxes as may be necessary for purposes in connection with the supply of energy." Section 12 provides that "No such box shall be placed above ground without the consent of the Local Authority, and every such box shall be used by the undertakers only for the purpose of leading off service lines and other distributing conductors, or for examining, testing, regulating, measuring, directing, or controlling the supply of energy, or for examining or testing the condition of the mains or other portions of the works, or for other like purposes connected with the undertaking, and the undertakers are authorised to place therein meters, switches, and any other suitable and proper apparatus for any of the above purposes. Having provided that the undertakers might construct "boxes," the section proceeded to limit the use of these boxes. His case was a double one: first, that these were not "boxes" within the meaning of the word as here used; and, secondly, that if they could be so construed, the use which it was proposed to make of them did not come within the second part of the clause. The electric power was to be transformed from a higher to a lower pressure. At first it was the universal practice to have a separate transformer for each customer upon his own premises, but it had since been found more economical to have the transformer transform the current at a particular point, and to use the conductors of secondary current to supply a number of houses within a limited area. It appeared

Digitized by Google

from the affidavits that the area most economical to supply in that way was one about 200 yards from the transformer, and the system had been introduced into America and recently into this country. There then arose the question as to where those transformers were to be placed. The undertakers here claimed the right, as a right, under their compulsory powers, to place them under the street. What the defendant Company desired in the present case was to make chambers of considerable size—10ft. 3in. deep, 7ft. 6in. long, and 5ft. 6in. wide. The Board of Trade had certain powers in the matter, and there had been proceedings and objections and discussions before the Board, by means of a reference. Sir Courtenay Boyle, when this particular point arose, pointed out that it was a question for the Courts and not for him, as it was a question of the construction of an Act of Parliament, and therefore not within the jurisdiction of the Board of Trade. Thereafter the defendant Company altered their phraseology considerably. They (the defendants) gave the plaintiffs, when they went before the Board of Trade, a plan of what they wanted to do, and they then rightly called these "transforming chambers," but they now called it a box which was to contain transformers—a manhole and ventilating apparatus. One of the regulations made by the Board of Trade for supply in this case, was that the converting stations were to be street boxes of sufficient size and suitable construction to contain several transformers, room to be provided to enable a man to enter the box and conveniently examine the transforming and controlling apparatus; but the Board had propounded these regulations upon the assumption that it was within the power of the undertakers to do that, the legality of which the plaintiffs now asked this Court to determine on the interpretation of the Act of Parliament. It was extremely inconvenient to the public, and for the public purposes for which the streets were vested in the Local Board, that these large chambers should be constructed under the streets. The Board based their action upon that consideration, and also upon the consideration of the public safety, for there had been recent instances of serious accidents occurring through the presence of these chambers in the streets. Mr. Channell then read the evidence of Mr. Crompton, an electrical engineer, who declared that "street boxes" had a well-known meaning, and applied to the small boxes beneath the pavement used to get access to the wires for testing and for leading off branches, and the word could not be reasonably construed to include transforming or converting chambers. Mr. Channell here added that the question was whether these undertakers were to have the right to get this use of the public streets without payment, or whether they were to construct these chambers in cellars or upon other private property which they could have for a small additional payment. The next affidavit read by the learned Counsel was made by Dr. John Hopkinson, whose evidence was on the same lines as that of Mr. Crompton.

Mr. GRAHAM HASTINGS then read the affidavit of Prof. Silvanus P. Thompson, who differed from the opinion of the plaintiffs' experts, and said that if the boxes were on private property they could not be so well looked after or kept sufficiently dry. He found that Clause 12 of the Act said that the boxes were to be such as were necessary for the purposes in connection with the supply of energy, including apparatus for the proper ventilation of the boxes; and all the apparatus which the undertakers proposed to place in the street boxes fell within that description. Affidavits which had been made by Sir F. Bramwell, Dr. J. A. Fleming, and Mr. Lawson, the defendant Company's manager, were also read.

Mr. CHANNELL submitted that the evidence showed that street boxes had all along been understood to be a very different thing from transforming chambers. When they wanted a place such as the defendants here contemplated, they called it a chamber and not a box, and his affidavits were precise to the effect that, until the present case, "street boxes" were never used for such purposes as the defendants had in view. But assuming it to be only a box, there was statutory prohibition of the use of such boxes, for their use was restricted to certain specified purposes. "Transforming" was a thoroughly well-known operation which had its known name. If it had been intended that operation should be carried on in these boxes, it would have been inserted in the clause in question.

Mr. CHUBB, on the same side, contended that Parliament had never considered the question of allowing transforming sub-stations to be formed under the public streets, and the defendants here were trying by means of a back door to secure that.

Mr. GRAHAM HASTINGS, Q.C., with whom was Mr. Cripps, Q.C., Mr. Shand and Mr. Braithwaite, for the defendants, said that the only question the Court had to determine was the construction of the 12th clause, and in approaching an Act of Parliament like that one had to consider what it was for and what the state of circumstances were at the time the Act was passed. The object of the Act was to enable the Company to supply electricity to a certain district, so that one would suppose that they would have all the necessary powers to enable them to carry out those objects. Also, one would expect to find, having regard to the fact that science was extending itself—and especially electrical science, which was supposed to have been in its infancy at that time—that the Legislature would have been very careful not to do anything which might preclude the Company from availing itself of any improvements conferred in carrying it into effect. Therefore one would expect to find—which he submitted they did plainly find—that the Legislature would have been careful not to introduce any word of art in the particular portion of the clause which was under consideration. He thought that it was impossible to read the terms of the 12th section without coming to the conclusion that every word used for that purpose was a word of ordinary and general signification in the English language, and not in any sense used in a technical way. It really seemed to him that inconvenience had nothing to do with the case. If the Company had got the power to do it, it was immaterial what the plaintiffs thought or felt. Mr. Channell's first point was, that what the defendants were proposing to construct was not a box at all. The first observation he had to make was that the word "box" was a most generic expression, and it might be applied to a species of infinite variety.

His LORDSHIP: Including coffins!

Mr. HASTINGS agreed. He submitted that the Legislature had chosen an expression with the widest possible meaning. He contended that the intention of the Legislature was that they would not use any words which should have any limitations. There was no limitation as to size or materials. Subject to the satisfaction of the Board of Trade, who had the public to watch over, they might make a box of any materials they liked—of brick, wood or iron; but it was not any the less a box in its generic sense, and there was nothing in that clause which said it was to be of any particular kind or description. The only thing was that it was to be for purposes in connection with the supply of energy.

Mr. CRIPPS, following on the same side, submitted with regard to Section 12 that there was no word of art at all in it, and said that all the affidavits, except so far as regarded mere questions of fact, were practically and substantially immaterial. The only question of fact which was material was in Mr. Lawson's affidavit as to the system in work in the City of London. His Lordship was aware that the defendants had power to enter upon and break up the street, and the only question was whether, in carrying out that power, they had authority to make this particular form of "street box."

His LORDSHIP intimated that he would reserve judgment, and judgment was reserved accordingly.

British Insulated Wire Company v. The Prescot Urban District Council.

This case came before Mr. Baron Pollock and Mr. Justice Wright on Monday last in the form of a special case, raising the point whether a contract without providing for a pecuniary penalty was void or not as construed by the Public Health Act, 1875, Section 174, Sub-section 2, by which it is provided as follows:—"Every such contract . . . . shall specify some pecuniary penalty to be paid in case the terms of the contract are not duly performed." The original action was commenced on May 18th last, and the questions of law arising therein were raised for the opinion of the Court by order of Mr. Justice Day.

On November 12, 1892, the plaintiffs and the Prescot Local Board entered into an arrangement whereby it was agreed that the Company should efficiently light the streets within the district of the Local Board, in terms fully set out.

After setting out that the agreement was sealed by both parties, the special case stated that the plaintiffs carried out the agreement by supplying the electric light from January 1, 1893, until March 31, 1895, and had been paid the amounts payable in accordance with the terms of the agreement for the supply of light to the end of the quarter ending June 30, 1894, and that the action was brought to recover £278. 9s. 9d., which included three quarterly payments of £87. 10s. respectively for October 1, 1894, January 1, 1895, and April 1, 1895, the balance being made up of three sums for extra lamps.

The question for the opinion of the Court was whether the agreement was void, or not binding upon, or not enforceable against, the defendants by reason that the agreement did not specify some pecuniary penalty to be paid in case the terms of the contract were not duly performed.

Mr. ARKLE, for the plaintiffs, said that the facts had been agreed, and the only point between the parties was whether the absence of a penalty clause in the contract vitiated it under the substitution. He contended that the clause in the Act regarding this was merely directory, and he cited the cases of "Young v. the Mayor of Leamington," "Melliss v. the Shirley Local Board," and "Noel v. Worcester" in support of his contention.

Mr. Baron POLLOCK, without calling upon counsel for the defendants, said that he was of opinion that the agreement was not binding, and Mr. Justice WRIGHT concurring, judgment was entered for the defendants, with costs.

Shelfer v. The City of London Electric Lighting Company (Limited) and Meux's Brewery Company (Limited) v. The City of London Electric Lighting Company (Limited).

On Wednesday last these cases came before the Court of Appeal, composed of Lords Justices Lindley, Lopes, and Rigby, it being the application of the defendants that the restraint imposed by the order of the Court on December 18th last might be suspended until the second motion day in next sittings.

It will be remembered that this was a case in which an injunction was granted against the defendants in respect of vibration caused to a neighbouring public-house.

It was ultimately arranged that the matter should stand over till next Wednesday, the time enlarged till then, with liberty to apply.

Edison and Swan United Electric Light Company (Limited) v. Gustav Strauss.

In the Chancery Division, on Tuesday, Mr. Graham asked leave of Mr. Justice Stirling to mention a motion in this case. The learned Counsel said that it was an action to restrain two kinds of infringement of a patent. The defendant was willing to submit to an order as to the first infringement, but was prepared to contest the other. He (Mr. Graham) therefore asked, in terms which had been egreed, an injunction to restrain Mr. Strauss from continuing the first infringement, and that the motion with regard to the second infringement should stand till the hearing of the action, the costs being reserved.

His Lordship made the order on the terms asked for.

Digitized by Google

Wood v. Woodhouse and Rawson United (Limited).

On Wednesday, Mr. HOWARD WRIGHT, on behalf of the Official Receiver and liquidator in this matter, stated that in regard to his Lordship's recent order that a meeting of the debenture-holders of the Company should be held with a view to ascertaining whether they were in favour of instituting proceedings against certain officers of the Company, a majority of the Six per Cent. Debenture-holders and a majority of the Five and a-Half per Cent. Debenture-holders (having only a second floating charge) were against the proposed proceedings, and the Ten per Cent. Debenture stockholders, who had a security on specific assets, were unanimously against the proceedings.

Mr. Justice VAUGHAN WILLIAMS asked what were the motives which had induced them to come to that view. Did they dissent from counsel's opinion on the subject, or think the suggested proceedings too risky, or that the people to be proceeded against were not worth powder and shot?

Mr. MACNAGHTEN, for some of the debenture-holders, said all these views had influenced the meetings. Those who wished to go on would have had to subscribe the necessary funds to enable the action to be taken.

Mr. CARTMELL said that a minority of the Five and a-Half per Cent. Debenture-holders wished proceedings to be taken, but did not want to be put to any expense in the matter.

Mr. Justice VAUGHAN WILLIAMS directed a further meeting of all three classes of debenture-holders to be held, in order to ascertain whether those who did not wish to go on were willing to give up all claims to any assets which might be produced by the proceedings in favour of those who wanted the proceedings to be taken.

CORRESPONDENCE.

SHIPBOARD GALVANOMETERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reference to that portion of Mr. Rymer-Jones's letter (see *The Electrician*, July 26th, p. 428) dealing with the figure of merit of my galvanometer when suspended for sea use, perhaps you will allow me to mention that for this purpose the suspending wires must necessarily be of sufficient strength and rigidity to prevent sagging of the coil from side to side and end to end as the vessel rolls and pitches.

For measurements on shore, however, sensibility can be augmented some five-fold by more finely suspending the coil, and nearly as much as ten-fold by also letting it swing freely from above, the current being led away below by a fine non-torsional wire spiral. It is simply a question of suspension, but except for very delicate laboratory observations, the ordinary plan of a top and bottom suspension is preferable, as this secures greater freedom from vibration, without a masonry pillar or other special support for the instrument. I may say that Messrs. Elliott Brothers supply coils wound and suspended for all requirements. You will oblige me greatly by inserting this letter in your columns.—Yours, &c.,

H. W. SULLIVAN.

Accident Insurance Law in Germany.—A recent German legal decision is to the effect that an accident insurance policy does not cover death from chemical but only from mechanical causes. The question arose upon the policy of a Dr. Oergel, who died last year, says the *Gas World*, from accidentally getting cholera-material into his system. The Court decided that the action of this is chemical, not mechanical. It is pointed out that the same argument would apply to sulphuric acid or soda acid; that even a fatal scald from a burst boiler or a burn from an exploding lamp produces death not through mechanical but through chemico-physiological action.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

SPECIAL NOTICE.—The 1895 (thirteenth) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. In addition to the old well-known features of the book, which are brought up to date, a quantity of new and useful matter has been added, rendering the book more than ever indispensable to the Electrical, Engineering, and Allied Trades. Price, 7s. 6d., post free 8s. 3d., abroad 9s.

The following New Books and Editions of "THE ELECTRICIAN" SERIES *can be obtained of the Booksellers or direct from the Publishing Offices:—*

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett (*now ready*). Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

A LARGE-SHEET TABLE, giving full particulars of the Electricity Supply Stations throughout the Kingdom, can now be supplied mounted on stout board, with cord for hanging. Price: Varnished, 3s. 6d.; Unvarnished, 3s. —each post free. A Map showing positions of Supply Stations throughout the country is mounted on the back of the Table, and a Coloured Map of Metropolitan Electric Lighting Areas and a large sheet of Electricity Supply Statistics are also mounted on some copies, the price of which complete, post free, is 5s.

A SHEET TABLE showing Total Capital Outlay and Receipts and Expenditure for the year 1894 of the Statutory Electric Supply Undertakings of the Metropolis is now ready, printed on thick paper, price 6d. each.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—By Mr. F. Marten Weymouth, is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson, price 6s. 6d., post free.

TENDERS INVITED.—The Corporation of Brighton require tenders for the supply and erection, at their electricity works, North-road, of evaporative brass tube surface condensers, electrically-driven air pumps, and exhaust and condenser pipings. Tenders must be in before 10 o'clock August 10th.

——— Tenders are invited by the Vestry of Hammersmith, London, W., for complete schemes for public and private lighting, and for the supply of motor power in the compulsory area of the Vestry's Provisional Order. Further information can be obtained of Mr. H. Mair, Surveyor to the Vestry. Tenders have to be sent in by 6:30 p.m. of Wednesday, September 4th.

——— The Electric Lighting Committee of the Wakefield Corporation invite tenders for the supply and erection of (*a*) boiler and fittings, mechanical stokers and engine, economiser, feed pump, injector, &c.; (*b*) steam alternators, condensers, oil filter, fittings, &c., steam, exhaust, feed, blow-off and sundry pipes, valves and water tank, &c.; (*c*) main switchboard and instruments; (*d*) cables, junction boxes, culverts, and trenching, &c.; (*e*) transformers and switchboard, &c.; (*f*) arc lamps and posts; (*g*) meters, and (*h*) overhead crane. Plans and specifications may be obtained from Mr. Robert Hammond, the consulting engineer, Ormond House, Great Trinity-lane, London, E.C., after Friday next, August 2nd, and tenders, addressed to the Town Clerk (Mr. Chas. Jas. Hudson), Town Hall, Wakefield, must be in by 2 p.m. on Saturday, August 24th. Some further particulars appear in our advertisement columns.

——— The Corporation of Cardiff require tenders for wiring and supplying and fixing of fittings for the electric light for the new bath in Guildford-crescent, Cardiff. Particulars of the Borough Engineer. Tenders to be in by 9:30 Wednesday, August 7th.

Digitized by Google

Tenders Invited.—Tenders are invited for the electric lighting of the King's Cross Constitutional Club, Halifax. Tenders by the 5th instant to the Chairman of the House Committee.

——— The Lord Provost, Magistrates, and Council of Edinburgh require tenders for the supply of (1) insulated concentric cable for high-pressure alternating current, and (2) for transformers. Specifications may be obtained from the Resident Electrical Engineer (Mr. E. W. Monkhouse), 5, Dewar-place, and tenders must be sent in to the Town Clerk (Mr. Thomas Hunter, W.S.), City Chambers, Edinburgh, by 10 a.m. on Friday next, the 9th inst. Additional particulars appear in our advertisement columns.

——— The General Direction of French Posts and Telegraphs is inviting tenders for the construction and equipment of a head telephone office in the Rue Chaudron, Paris. Tenders to the Direction Générale des Postes et des Télégraphes, 103, Rue de Grenelle, Paris, by the 8th instant.

——— The Blackpool Corporation are willing to receive tenders for the right of user for a period of seven years of the electric tramways in Lytham-road, and which extend northwards from the southern boundary of the borough for about two miles. An approved overhead wire and trolley system is to be used for a portion of the route, and for the remainder the conduit or central channel system now laid down by the Corporation under the roadway. All particulars can be obtained of the Town Clerk, to whom tenders have to be sent in by August 17th before 12 noon.

——— The Vienna (Austria) Municipal Authorities invite tenders for a railway system worked by electric power in the municipal district of Vienna. The Municipality itself acquires the concession for the building and working of the track. Competition is now open for the execution of the plans, and tenders are invited for the construction and working of the lines. An official notice states that direct communication is to be facilitated between the centre of the first district and the outlying districts and summer resorts. The lines are to pass as near as possible certain important spots, and must in addition touch the principal railway systems of the city. For this purpose both radiating and circular lines will be necessary. Some portion of the line will have to be worked underground, and facilities will be offered for overhead running for the other portions. Firms tendering will be required to specify the gauge, curves and gradients, the positions of the distributing stations, types of cars and all other essential details. The track is to be uniform throughout the municipal district, with a uniform tariff, to be regulated under conditions which are set out in the forms of tender. Tenders have to be sent in to the Wiener Stadt Bauamt, Rathaus, Vienna, not later than November 4, 1895. Further full information can be obtained at the same address from the Mayor.

Tenders Accepted.—For the electric lighting of part of the St. James's Club, 106, Piccadilly, London, W. (Mr. W. Howard Tasker, M.Inst.E.E., 12, Pembroke-road, Kensington, W., consulting engineer).

The following tenders were received :—

Belshaw and Co. (accepted)	£467	14	9
Verity and Sons	432	10	0
Moody Bros.	475	5	0
Drake and Gorham	518	18	0
Clarke and Co.	536	6	0
Crompton and Co.	573	10	0

——— The following tenders were received for the lighting by electricity of the Dewsbury Pioneers' Industrial Society's premises :—

G. A. Steinthal, 41, Piccadilly, Bradford, (accepted conditionally)	£730	0	0
Electrical and Mechanical Supply Company, Leeds	1,580	0	0
Lowcock, Hill and Co., Manchester	1,250	0	0
J. A. Edmondson, Leeds	1,185	5	1
S. J. Waring and Son, Manchester	1,075	0	0
Rhodes and Webster, Bradford	990	0	0
H. F. Joel and Co., London	952	17	0
Paterson and Cooper, London	932	0	0
Crompton and Co., London	915	0	0
Thorpe and Waring, London	900	0	0
C. A. Parsons and Co., Newcastle	865	0	0
Graham, Chapman and Co., Morley	829	15	0
A. Hirst and Son, Dewsbury	777	0	0*
Manchester Edison-Swan Company (Limited)	743	0	0*
Bennett and Druce, Preston	739	0	0
Nunns and Sykes, Halifax	735	0	0
Maunsell Mercier and Co., Manchester	727	0	0
Electrical and Gen. Engineering Company, London	720	0	0
A. R. Turner, Dewsbury	713	10	0
Ullathorne and Hartley, Bradford	709	7	0
A. Sykes, Huddersfield	667	10	0
Sharp and Kent, London	616	0	0*
B. Verity and Sons, Manchester	610	0	0*

*The supply of electroliers is not included in these quotations.

Tenders Accepted.—The St. Giles's Board of Works, London, W.C., has accepted the tender of Messrs. Pontifex and Sons for the installation of the electric light in the offices of the Board for the sum of £96.

——— The Salford School Board have decided to accept the tender of Messrs. B. Verity and Sons for wiring and fitting the new offices of the Board for the electric light, and for fixing electric bells and speaking tubes. The amount of the tender is £221.

——— The Electric Lighting Committee of the Portsmouth Town Council have decided to recommend the following tenders for cables for acceptance by the Council :—

For conduits and I.R.-covered mains (W. T. Glover and Co.)	£12,357
For compound-covered mains (British Insulated Wire Company)	486

Tenders Received.—The Electric Lighting Committee of the Shoreditch Vestry, London, E.C., have recommended the acceptance of the tender of Messrs. Manlove, Alliott and Co. (Limited), 57, Gracechurch-street, London, and Nottingham, for the erection of a chimney shaft at the electricity works for the sum of £2,683. This was the lowest of four tenders sent in, the highest of which was £3,420.

Sale by Auction.—Messrs. Wheatley Kirk, Price and Goulty will sell by public auction on Thursday, the 15th inst. (at 10 for 11 o'clock) the entire contents of the turbine works of Mr. C. L. Hett, of Brigg (who is declining the business). Included in the sale are a Marshall steam engine, lathes, planing machines, loose plant and utensils, several finished and many unfinished turbines of various types, centrifugal pumps, &c. Illustrated catalogues and all particulars may be had of Mr. Chas. Louis Hett, Turbine Foundry, Foundry-lane, Brigg, Lincs., and from the auctioneers, Messrs. Wheatley Kirk, Price and Goulty, 49, Queen Victoria-street, London, E.C., and Albert-square, Manchester. Some further information is given in our advertisement columns.

Appointments.—The Gas and Electricity Supply Committee of the Bradford Corporation have appointed, subject to the approval of the Council, Mr. A. H. Gibbings electrical engineer at the Corporation electricity works, in succession to Mr. S. W. Baynes, who was recently appointed electrical engineer to the St. Pancras Vestry. Mr. A. H. Gibbings has been electrical engineer to the Hull Corporation for the past two years, and had previously held a similar appointment with the Hove Improvement Commissioners. The salary at Bradford commences at £300 per annum.

——— Mr. Wm. Smith, who was for some time engineer at the Asylum at Claybury, Essex, has been appointed electrical engineer at the Municipal Technical School, Birmingham.

Appointments Vacant.—The Governors of the Woolwich Polytechnic are willing to receive applications for the posts of lecturer in physics (salary £110 for a session of about eight months) and lecturer in mechanics (salary £70 for a session of about eight months). Some further particulars are given in our advertisement columns, and applications must be sent in by the 23rd inst.

——— The Governing Body of the Northampton Institute, Clerkenwell, E.C., are prepared to receive applications for the appointment of a principal. The salary attached to the office has been fixed at £600 per annum. Applications must be sent in by September 4th to Mr. J. J. Lambert, 8, Dowgate-hill, Cannon-street, London, E.C.

Business Changes.—Messrs. Easton, Anderson and Goolden (Limited) notify us that their instrument department, carried on at Woodfield Works, Harrow-road, London, W., has been sold to Messrs. Evershed and Vignoles (Limited). It is pointed out that the management of this department has, ever since its commencement, been in Mr. Evershed's hands, and that Mr. Vignoles has been associated with him for the past six years. The existing orders and all trade liabilities are taken over by Messrs. Evershed and Vignoles as from January 1st last. The new firm notify that every effort will be made to maintain the reputation of the business originally founded by Messrs. Goolden and Trotter in 1886, and to turn out instruments of the highest class. The whole of the Evershed patents pass into the new firm's hands, including the Richards-Evershed system of electrical ships' telegraphs now being introduced into the Navy. No change in the general scope of the business is in contemplation, but the manufacture of electrical and kindred apparatus for the special requirements of the engineering industries continues to be an essential feature of the business. The Directors of the new Company are Prof. W. E. Ayrton and Messrs. H. M. Gregory, S. Evershed and E. B. Vignoles, and the manager of the factory is Mr. A. Schneider, M.A. The Company's telegraphic address is "Dorothea London." Mr. A. Montagu Shepherd, of 32, Albany-road, Ealing, W., represents Messrs. Evershed and Vignoles in London and district. Messrs. Easton, Anderson and Goolden are making further extensions to their shops at Erith (where the works are now concentrated) in order to expedite the carrying out of large contracts.

Digitized by Google

DISSOLUTIONS OF PARTNERSHIP.—Messrs. R. P. Gerland and F. Tomlinson, carrying on business as electrical engineers and electro-platers under the style of Gerland, Tomlinson and Co., at Accrington, have dissolved partnership. Debts by Mr. R. P. Gerland.

——— The partnership hitherto existing between Messrs. Wm. Maxwell and John Samuel Ross, under the style of Maxwell, Ross and Co., telephone and electrical engineers, at Britannic Works, Bradmore-lane, King-street, Hammersmith, London, W., has been dissolved. Mr. W. Maxwell will continue to carry on the business on his own account at the same address, and Mr. J. S. Ross has established a similar business at Bath-street, Glasgow.

BANKRUPTCY.—Notice is given that the first meeting of creditors in the bankruptcy of Ronald A. Scott, electrical engineer, The Elms, Acton-hill, London, W., will take place on Wednesday next, the 7th inst., at the Official Receiver's office, 95, Temple-chambers, Temple-avenue, London, E.C., at 3 p.m. The examination takes place at the Town Hall, Brentford, on September 17th, at 2:15 p.m.

LIQUIDATION.—At a meeting on June 26th a resolution was passed that Armstrong's Glass Company (Limited), manufacturers of specialities in glass for electrical purposes, 26, Waterloo-street, Birmingham, be wound up. This resolution was confirmed on July 15th, when Mr. C. Butler, Brookleigh, Westfield-road, Edgbaston, Birmingham, was appointed liquidator.

"HELIOS" ARC LAMPS.—A new edition of the catalogue of the International Electric Company, which relates exclusively to arc lamps and accessories, has just been issued, and copies can be obtained by the trade from the Company's offices, 55, Red Cross-street, Barbican, London, E.C. The list is well printed, and contains a number of illustrations and particulars of these lamps, which are in use at the General Post Office and on a long list of circuits, the names of which are given. Included in the accessories are particulars of resistances, the "Helios" transformers, choking coils, suspensions, pole-arms and brackets, winches, &c., and lengthy directions are given for erecting and operating "Helios" lamps. A price list of "Phœnix" carbons is also included.

ENGINEERING MAGAZINE.—The July number of this magazine is now ready, and is a really fine example of high-class letterpress printing. The contents include: "The Signs of the Times," by Edward Atkinson; "The Trolley in Competition with Railroads," by Clarence Deming; "Uninhabitable Houses in City Slums," by Wm. Stevenson; "Improving the Delaware at Philadelphia," by John Birkinbine; "Is the Inventive Faculty a Myth?" by Wm. H. Smyth; "Illuminating Gas for Heating Purposes," by Frederick Siemens; "Robert Fulton and his Steamboats," by T. C. Purdy; "James Rumsey, Steamboat Inventor," by James Weir, jun.; "Business Opportunities in Colombia," by C. F. Z. Caracristi; "The Magnetic Separation of Iron Ores," by C. M. Ball; "Production up to the Power Limit," by H. L. Arnold; and the increasingly useful Review of the Industrial Press. The new number, and nearly all back issues, may be obtained at the offices of the European Edition, 1, 2 and 3, Salisbury-court, Fleet-street, London, E.C.

THE JOURNAL.—Part 118 is now ready of the *Journal* of the Institution of Electrical Engineers, containing Papers on "A Magnetic Tester for Measuring Hysteresis in Sheet Iron," by Prof. J. A. Ewing, F.R.S., and "On the Recent Development of the Single-acting High-Speed Engine for Central Station Work," by Mark Robinson, M.I.E.E., with the discussions thereupon; communications on "The Zero-Torque Electricity Meter," by Joseph Edmondson, and "Daily Insulation Testing of Telegraph Lines," by W. H. Preece, C.B., F.R.S.

TELEPHONE DIRECTORY.—A Supplement is just issued by the National Company to the Telephone Directory issued in May, 1894. This Supplement contains the names and addresses of subscribers added to the metropolitan exchange since the publication of the Directory, also additional call-rooms and a number of alterations and corrections.

ALDERLEY EDGE (MANCHESTER).—At the monthly meeting of the District Council on Monday last a letter was read from Mr. S. V. Clirehugh, electrical engineer, of Manchester, asking if the Alderley Council were prepared to dispose of their Provisional Electric Lighting Order. After discussion the Clerk was instructed to reply that the Council were prepared to dispose of the Order on adequate payment being made, and on an undertaking being given that the electric lighting would be carried out in accordance with the views of the Council.

BERLIN.—Messrs. Siemens and Halske have completed an extensive electric lighting installation at the Old Palace for the Emperor William. The plant includes a battery set, and steam power equal to 200 H.P. has been put down.

BIRMINGHAM.—Reports from this district state that an improvement in business is noticeable, more particularly in those branches of industry associated with the electrical trades, and especially in fittings, apparatus and accessories.

BIRMINGHAM MUNICIPAL TECHNICAL SCHOOL.—The Committee of this institution have instructed Mr. W. H. Whitehouse, who is lecturer on telegraphy and telephony at the institution, to provide a complete telephonic installation for the new Technical School. The work will comprise a double-cord (Western Electric Company's pattern) Standard switchboard, which is to be placed in the Curator's office, and instruments in the various Professors' rooms and laboratories, &c., with metallic circuits throughout. The system will thus be available for business purposes, as well as providing a complete working exchange for teaching and lecture demonstration.

BRADFORD.—The Gas and Electricity Committee of the Town Council have decided to put down new condensers at the electric supply works, at a cost of £2,200.

BRIGHTON.—The Brighton Borough Council have decided to provide an electrically-driven passenger lift for the Town Hall, at an estimated cost of £538.

BROMLEY (KENT).—At the last meeting of the District Council a letter was read from an electric lighting syndicate asking the assistance of the Council in introducing the electric light into the district, the Bromley Provisional Order having lapsed. The letter was referred to the Standing Orders Committee.

CHAPEL LIGHTING.—The new chapel at Berkhamsted School (Herts) is now complete, and is lighted throughout by electricity in a similar manner to the installation at the school.

CHURCH LIGHTING.—The Tayler Smith Electric Company have been entrusted with the order to instal the electric light at St. Mary's, Aldermanbury, in the City of London. About 200 incandescents of varying candle-powers will be used.

DEVONPORT.—At the last meeting of the Town Council two letters were received from electric lighting companies, notifying their intention of applying for Provisional Orders to supply electric current in the district. After a brief debate on the Streets and Highways Committee's report, when the electric lighting question was again discussed, the Town Clerk hoped that the Council would secure its own Provisional Order. Mr. Paris, on behalf of the Brush Provincial Company, attended before the Committee and explained the terms upon which the Company would, if successful in obtaining an Order, be prepared to hand over the undertaking to the Council after a certain period. The subject was referred back to the Committee.

DOVER.—The Dover Electricity Company propose to extend their electric lighting mains to the Maison Dieu-road, which is outside the area included in their original scheme, and the Town Council have sanctioned the proposal.

EDINBURGH.—On Wednesday evening the public electric lighting was extended as far east of the city as the foot of Canongate, and as far south as Hope Park. Under the presidency of Mr. Councillor Waterston, 200 residents assembled in the Canongate Institute for the purpose of inaugurating, as it were, the switching on of the current. Councillor Mackenzie, the convener of the Corporation Electric Lighting Committee, said that, so far as it had gone, the Edinburgh electrical installation had been one of the most successful that was to be seen anywhere. The light had never been out since it was turned on on April 11th last for a single second, nor had there been the slightest hitch of any kind. The switching on of the light at Canongate attracted a large crowd.

FAREHAM.—In regard to the litigation in progress between the District Council and the local Electric Light Company, the former at their last meeting decided to "brief" three counsel. Of course, an angry debate preceded the adoption of this heroic course.

FRENCH SUBMARINE TELEGRAPHS.—The French Press is anxious that no opportunity shall be missed of claiming at least a full share of submarine cable enterprise. The following is a *Times* clipping from the *Revue Scientifique*:—France has at the present time 5,330 miles of submarine cables belonging to 54 different lines, while there are three French companies possessing submarine cables, namely, the French Telegraph Company, from Paris to New York, with 4,080 miles; the Commercial Cable Company [!], with seven cables having a total length of 10,495 miles; and the French Society of Submarine Telegraphs, with 15 cables of a total length of 5,260 miles.

GLASGOW.—The report of the Electric Lighting Committee of the Town Council for the past year, to which reference was made in our last issue, states that the quantity of electricity sold during the past year to private consumers, irrespective of public lighting, was 713,916 Board of Trade units, being an increase over the preceding year of 31·43 per cent.

HACKNEY (LONDON, N.E.).—The Hackney Vestry have finally decided to adopt a combined electric lighting and refuse destructor scheme for the parish. Mr. F. H. Medhurst has been appointed consulting engineer for the scheme.

Telephone Trunk Line Service.—A circular is issued by the National Telephone Company giving particulars of the extensions of trunk line service recently completed by the Post Office, and of which the National Company's subscribers have now the use at charges varying from 3d. to 8s. 6d. per conversation of three minutes' duration. The full list of towns between which trunk line communication is now possible, and the charges are set out fully in the table above.

Hampstead (London, N.W.).—The report of the Electric Lighting Committee presented at yesterday's meeting of the Vestry stated that there were on June 22nd last 11,000 8 c p. lamps connected to the Vestry's mains, and that owing to the large extensions now being made, and to the applications from new customers, they estimate that at least 20,000 8 c.p. lamps will be connected by Christmas next. As the total capacity of the present plant at the generating station is 12,000 8 c.p. lamps, the Committee recommend that additional plant be ordered at once, at an estimated cost of £2,200.

Leeds.—The Yorkshire House-to-House Company intend to extend their mains to Chapeltown, so that the residents in the district and occupiers of business and other premises along the important thoroughfares *en route* may be able to avail themselves of the advantages of the electric light. The existing mains terminate in New Briggate, and it is now intended to carry them along North-street and Chapeltown-road and Harrogate-road, as far as the tramway terminus. The work will be put in hand immediately, and it is expected that current will be available early in the autumn. Already a considerable number of residences and business establishments are being wired and fitted.

Liverpool.—Notice has been given of the calling of a special meeting of the City Council to finally consider the advisability of taking steps to obtain an Electric Lighting Provisional Order for the supply of electric current within the area of the City of Liverpool. The ultimate decision in this matter depends practically upon the result of the application to Parliament for power to extend the city boundaries.——The Howe Electrical Engineering Company have recently completed several large installations in and near this town, including the lighting of Thornton Hall, near Neston, Cheshire, and the Paddington Theatre of Varieties, Edge Hill. For the latter 580 16 c p. incandescents and 6 arcs are used. Engine power is supplied by a Crossley latest type gas engine, with a flywheel weighing nearly 4 tons. Messrs. Laurence, Scott and Co., of Norwich, for whom the Howe Company are sole agents in Liverpool and district, supplied the dynamo, which has a capacity at full load of 240 amperes at 110 volts. The switchboard and distribution boards were specially designed by the Howe Company to meet the special requirements of the theatre. It is possible to change the colour and control the lights on battens, flies, footlights, stage, and in the house from any section, and to graduate them from full intensity down to absolute extinction.

Metropolitan Asylums Board.—A special committee appointed in October, 1894, to consider and report as to whether the arrangements for advertising for and accepting tenders were capable of improvement, has just issued its report, and, in stating that, in their opinion, the existing practice was faulty, recommend, amongst other matters, that a list of manufacturers of and dealers in manufactured articles be established, and then any firms applying to be admitted to this list should furnish two satisfactory references; further, that clerks to Chambers of Commerce should be consulted as to the firms in their districts who may be likely to supply the manufactured articles; and also that the Contract Committee of the Board should not be obliged to advertise for tenders in all cases as at present, but should be authorised to obtain tenders from a limited number of firms selected from the specially-prepared list, or to make contracts with producers direct after reporting to the Board the course deemed best in each case.

Portsmouth.—An important communication from the National Company, on the subject of placing the telephone lines underground, was considered at the last meeting of the Town Council, and was ultimately referred to the Streets Committee for inquiry and report.

St. George's, Hanover Square (London, W.).—The Joint Vestry Hall Committee have presented a report recommending that the Board room and offices be lighted electrically at a cost of £150 each to the Guardians and Vestry, and on the consideration of this report at the last meeting of the Vestry Mr. Bromwich said that, while not hostile to the introduction of the electric light, he thought they should wait until they had all the figures before them, and he therefore moved the adjournment of the question. After discussion this suggestion was adopted.

St. Pancras (London, N.W.).—The Electricity Committee of the St. Pancras Vestry have declined to sanction the laying of mains by the London Hydraulic Power Company for the service of business premises in Charlotte-street, to extend along Tottenham Court-road, Windmill-street, and across Charlotte-street. The refusal is owing to the fact that the Committee view the Company as a possible competitor with their electricity works for the supply of motor power.

Poplar (London, E.).—The District Board of Works have received a communication from the Board of Trade intimating that they are prepared to defer the question of the revocation of the Provisional Electric Lighting Order for one year.

Sheffield.—The School of Art is to be lighted electrically. About 200 incandescents will be used. The local electric light company are busily engaged in extending their mains.

South African Imports.—For the period from June 26th to July 23rd the imports into South Africa from Great Britain of electric fittings amounted to £4,894; of telegraph material, £4,139.

Digitized by Google

SOUTHAMPTON.—The Town Council intend to erect additional electric cranes at the Quay, and they have instructed the Wharfinger and Mr. J. G. W. Aldridge, their electrical engineer, to visit Rotterdam and other Continental ports, to inspect the most recent and improved types of electric cranes in work there. The Electrical Engineer and Surveyor have also been instructed to prepare plans, specifications and estimates for the proposed electric generating plant at the Town Quay. The Southampton Electric Light and Power Company are reducing the price of current from 8d. to 7d. per unit, with liberal discount to large consumers.

SOUTH RUSSIA.—German and Austrian firms are just now paying great attention to this district, where the question of the public lighting of several towns by electricity is under consideration by the authorities.

TELEPHONIC EXTENSION IN GERMANY.—A telephone line is being erected between Coblenz and Bingen, two important points on the Rhine.

TELEPHONE TRUNK LINE CHARGES.—A representation has been made to the Postmaster-General by the Leeds Chamber of Commerce, pointing out that many of the principal telephone subscribers would prefer to make an annual payment for the use of the trunk lines, in preference to separate payments for each use of the wires. A reply has been received to the effect that the present system has been adopted after mature consideration, and that, therefore, no hope is held out of any alteration being made.

TECHNICAL EDUCATION.—The *Technical Education Gazette*, which is the official circular of the Technical Education Board of the London County Council, in its July issue, contains a number of Examiners' Reports on the Intermediate Scholarships Examination in the awards of Intermediate County Scholarships. The examiners are able to report very satisfactory averages in Elementary Mathematics and Pure Mathematics. In Electricity and Magnetism Prof. H. Stroud reports : "The answers of the candidates were in nearly every case very satisfactory. With but one or two exceptions, the answers were expressed neatly and concisely, and showed a thoroughly intelligent appreciation of the fundamental principles of the subject. One very satisfactory feature of the examination is the evidence that the candidates give either of having witnessed the various experimental illustrations referred to, or of having performed the experiments themselves." In Heat and Light, Principal Tomlinson reports that four girls and 24 boys took this subject; the boys acquitted themselves satisfactorily, the girls unsatisfactorily. In Chemistry (Theoretical) the result of the examination was disappointing, better results being shown in the Practical Chemistry section.

THE ELECTIONS.—The return of members to Parliament is now practically complete, and it is satisfactory to record the fact that few candidates connected in any prominent manner with the electrical industries have proved unsuccessful in the contest. Amongst those who have secured election may be mentioned the Right Hon. D. R. Plunket, Q.C. ; Sir John Pender, G.C.M.G. ; Sir Albert K. Rollit, the Hon. W. St. John F. Brodrick, Messrs. Gerald W. Balfour, James Pender, J. W. Maclure, W. Cuthbert Quilter, E. Boulnois, W. Hayes-Fisher, and W. D. Cruddas, all of whom sit on the Government side of the House. The candidates who were rejected include the Right Hon. Arnold Morley, the Hon. Mark F. Napier, Sir H. E. Roscoe, Mr. J. Fletcher Moulton, Q.C., Messrs. R. Maguire, C. Burt, E. M. Underdown, Q.C., J. Seymour Keay, and E. H. Bayley. The rejected all sought election as supporters of the Opposition. Amongst the few instances where father and son both sit in the House of Commons may be mentioned that of Sir John Pender and Mr. James Pender.

TOXTETH PARK (LIVERPOOL).—The refuse destructor works recently erected by the District Council, and the approaches thereto, are now lighted electrically. The electrical installation has been carried out under the supervision of Mr. W. G. P. Macmuldrow, electrical inspector to the Liverpool Corporation, at a cost of £237. 10s.

WANDSWORTH (LONDON, S.W.).—The County of London Company have notified the District Board of Works of their intention to lay conduits for electric light mains in the Streatham High Road, and the Board have decided to offer no opposition to the laying of conduits in Putney-hill.

WESTERN AUSTRALIA.—A return recently prepared for the Minister in charge of the Post and Telegraph Department, gives comparative figures between the business done in the telegraph branch for the years 1887 and 1894. In 1887 telegrams transmitted numbered 114,116, for which revenue amounting to £12,702 was received. In 1894 the number of messages was 446,780, representing £37,483. In 1887 there were 2,821 miles of telegraphs erected, and 38 stations, and in 1894 a total length of 5,010 miles and 73 stations. For the last quarters of 1887 and 1894 the revenue was £3,259 and £12,578, from 41,095 and 127,486 messages respectively.

WIMBLEDON (SURREY).—The District Council considered the electric lighting question at their meeting on Wednesday, when, after a very lengthy discussion, it was decided to discontinue the present system of street illumination, and to light the whole town by electricity. The cost of the initial installation is estimated at £31,000, and the annual cost of maintenance at £3,750. The scheme is to provide for the erection of arc lamps in the main thoroughfares, and 1,000 32 c.p. incandescents in the remaining streets.

ANNUAL OUTING.—The employés of the Consolidated Telephone Construction and Manufacturing Company held their annual bean-feast on Saturday last at Box Hill, Dorking, and the day passed in good fellowship, to which all present contributed. The probability that this would be the last bean-feast from London (the works being removed to the country shortly) gave extra zest and kindredship to the proceedings. A cricket club has been established, and in the coming winter it is proposed to establish a football club, for which challenges are invited.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

CROMPTON AND CO., LIMITED.—The report of the Directors of this Company, which will be presented to the meeting at Cannon-street Hotel, London, E.C., on Friday next at three o'clock, states that the net profits for the year to 31st March were £6,953. 10s. 11d., and net revenue, after providing for debenture interest, &c., £2,343. 15s. 9d. £1,000 is set aside for contingencies and doubtful debts, and £1,343. 15s. 9d. is carried forward. The agreements with Messrs. R. E. Crompton and J. F. Albright to act as Managing Directors of the Company having expired, the Board have made arrangements for a continuance of these gentlemen's services. The works at Chelmsford are kept extremely busy.

COMPANIES' MEETINGS AND REPORTS.

City and South London Railway Company.

The twenty-second ordinary general meeting of the proprietors in this Company was held on Monday at Winchester House, Old Broad-street, under the presidency of Mr. Charles Grey Mott.

The SECRETARY (Mr. W. F. Knight) read the notice calling the meeting, the seal was affixed to the stock and share register, and the report of the Directors was taken as read.

The CHAIRMAN: It now becomes my duty to move—

"That the report and statement of accounts for the half-year ended June 30, 1895, now presented to the meeting, be received and adopted."

Although we are able to recommend the payment of a slightly increased dividend, the result of the working of the past half-year has been somewhat disappointing. We began the half-year very well. Our traffic showed a steady and regular increase, and we hoped that at the end of this half-year we should have a very satisfactory report to present to you, but, unfortunately, as soon as the hot weather set in, at the end of March, our traffics began to fall, and we suffered so much that at the end of the half-year very little of the improvement we had obtained in the first part of the period remained. We should be still more disappointed with this result if it had not been that the same fate has befallen nearly all the railways of this country. From one cause or another they have in the past half-year all, or nearly all, shown a very heavy decrease, while most of them are reporting decreased dividends. I am glad to say that that is not our case, but that, unsatisfactory as the half-year has been, we are able to propose a slightly increased dividend. If you will turn to the accounts you will see from the capital account that we have received from the issue of debenture stock a sum of £18,000, and a premium on the same of £5,426, making together £23,426. We have spent in the half-year on capital account £2,164, and have taken from the balance at our bank £2,275, and we have paid off £23,200 of the Five per Cent. Debentures. The expenditure on capital account has been on various small matters. Turning to the more interesting part of the accounts—the revenue account—the receipts from passengers other than season ticket holders show a decrease of £335, but the increased receipts from season tickets amount to £482, so that there is an increase in passenger receipts of £147. There have also been increases from parcels of £30, and in transfer fees of £8, making a total increase of £185; but, on the other hand, there are decreased rents £59, and a decrease in sundries of £20. Deducting these from the £185, there remains a net increase of £106. The decrease in rents arises from some empty properties, which we hope we shall let before long. With regard to the expenditure the outlay on maintenance shows a decrease of £35, locomotive expenses are £194 less, carriage repairs are £28 more, traffic expenses are £123 higher, the general charges show an increase of £48, and we have paid £106 more on account of passenger duty. There is a decrease of £4 in law charges and of £43 in rates and taxes. The total result is that there is a net increase in the expenses of £29, so that they are practically the same as they were a year ago. The decrease in the locomotive department and the increase in the traffic expenses are partly due to the different modes of charging the accounts. The large increase of £106 in passenger duty is owing to the fact that we raised the fares, as you know, from Stockwell, and the consequence was we became liable for passenger duty on those fares, whereas with the former fares we were not so liable. The fares to Stockwell have now been reduced, so that we are no longer liable for passenger duty on them. The result of the revenue account is that we have a balance to carry to net revenue account of £9,381, to which interest of £47 and the balance of £950 from the last account have to be added, making a total of £10,379. Debenture interest absorbs £3,959, and the Preference interest £1,912, while the dividend which we recommend on the Ordinary stock, at the rate of 1½ per cent. per annum, will require £3,543, leaving a balance of £964 to be carried forward to next half-year, or £14 more than we brought into the accounts on January 1st. The working expenses, comparing this half-year with the corresponding period of 1894, amount to 61·5 per cent. of the receipts against 61·69 per cent. last year, showing a small decrease; or if we take off the cost of the lifts, as we generally do, the amount is about 52 per cent., which is a fairly low rate of working, although we hope to get that very much lower some day. The locomotive expenses per train mile are 6·10d. this half-year against 6·22d., showing a satisfactory decrease. If you deduct, as we have done before, the carriage of coal, it comes out at about 4½d. The train miles run show a decrease of 3,104 in the half-year. The receipts per train mile have risen from 2s. 1½d. to 2s. 2½d. this year, in consequence of the increased fares charged, which were explained at our last meeting. The receipt per passenger has also risen from 1·61d. to 1·82d. The average number of passengers per train, on the other hand, has decreased from 48½ to 46¼, including an estimate for the season ticket holders. You will see from the statement on the first page of the report that the number of passengers has decreased this half-year, taking out the season ticket holders in both cases, from 3,383,000 in June, 1894, to 3,113,000 in the half-year to June 1895, showing a decrease of 270,000 passengers in the half-year. That has been compensated for to some extent by the increased fares and the increase in the receipts from the season ticket holders. Still, the total number of passengers shows a very distinct and decided falling off. This is no doubt partly owing to the increased fare charged and partly to the extraordinarily fine weather we had in the last three months of the half-year. As you know, fine weather does not suit this railway. You will perhaps observe that there is no mention in this report of any progress being made in the direction of putting on motor car trains. The reason of that is that although we told you last half-year that we had a motor car train, and that it was running, and was satisfactory as far as it went, our experience of it has not made us very anxious for the conversion of the rest of the stock. It is a very expensive operation, and will take a long time to do, and there are definite reasons why we think it should not be carried out at present. The most important of these is that at the last meeting you determined we should go on with the extension as far as Finsbury Circus. When that extension is completed we shall be running, and able to run, heavier trains—longer trains—conveying very many more passengers, and probably we shall endeavour to run those trains at a more rapid rate than the present. All this will require very much more powerful motors, and if we were to convert the present trains at a very large expense they would have the present motor power on them, which would not be sufficient for the heavier trains. The time, too, that would be occupied in converting the present stock would be very considerable unless we went to a very large and unwarrantable expense, and we think it better to postpone any operation in that direction until the new extension of the line is completed, when we can put on the larger and more powerful motors to the trains. By postponing this we shall save a very considerable amount of expense that would otherwise be wasted; but at the same time we have been very anxious, if we could, to provide, for the increased traffic which we hope we shall have next winter, more accommodation than we have at present. Our engineer and manager have put their heads together to see if something could be done to effect this object. Our difficulty is at the King William-street station and the small accommodation there. We have always been anxious if we could to alter that station so as to give more accommodation, but the difficulty and expense have made it almost insuperable. Our engineer, however, has at last devised a plan by which in the limited space at present at our disposal he can alter the station so as to make it similar to that at Stockwell, with a centre platform and two lines of rail on each side. By that means we shall be able to work three or four trains per hour more into that station than we can at present, which will give us about 25 per cent. additional accommodation, or very much the increased accommodation we had hoped for from the motor car trains. It will prevent our converting into motor car trains there, because the alteration will so far shorten the platform that we could not get the trains into it, but we think that without any very heavy expense we can alter that station and give an increased service of trains, increased accommodation, and carry a larger number of people. This is the most economical thing that we can do under the circumstances. We are trying in every way we can to reduce our expenditure. We now run ordinarily two of our large engines to drive the dynamos which work the line, but there are times, in the middle of the day and on Sundays, when a great deal of that power is wasted when we require rather more than one engine, but not anything like the power given by two great engines. We have now ordered a small engine and dynamo, which will reduce the cost of working to a small extent and economise in that direction. We shall be able to use one of the large engines and a small one instead of two large ones during the busy time of the day and on Sundays. We have always had a supply of water, but it has not been efficient, and we have had to buy water. We have now been able to increase the supply from our own sources, and we hope to economise a little in that direction. We are also proposing to run an additional number of two coach trains during the quieter hours of the day and on Sundays, and are proposing to order some coaches for that purpose. I believe we shall be able in all these things to show you within the next twelve months a further decided decrease in the cost of working the line. The lighting of the carriages has been a matter we have been very desirous of seeing improved. We have done something towards improving it in the past half-year; but it is not satisfactory yet, and we are going to try some further experiments with the idea of still further improving that light. As regards the question of the extension of the line, after we got the authority last February to proceed, the first question we had to settle was as to the engineering of the line, and we made arrangements with Mr. Greathead for carrying out that extension. He has had to prepare the plans, which are very elaborate and have taken a great deal of consideration, because we do not want to have any mistake with them, and our desire was to settle them with a view to the greatest efficiency. We have arranged the plans at last as to the stations, and we are now in negotiation for the sites. I told you in February that I thought it would probably take us twelve months before we should be able to acquire the sites, and it seems as if the time I then mentioned was not far from being correct. It is a slow process, however, if you are to do it economically. The Bill for the Clapham extension has received the Royal Assent. It extends the time for completing that portion of the line for another three years, and also gives us certain powers to which you gave your approval last half-year. The result altogether of the half-year's working is, as I say, not unsatisfactory. We have gone on and we are progressing, although steadily; but if the receipts of the first three months of this half-year, which showed an increase of about £700, had been continued throughout the half-year, we should have been able, I think, to have recommended a dividend at the rate of 1¾ per cent., instead of 1½ per cent. as at present, but unfortunately the decrease in our receipts in the last three months diminished our increase to the small sum I have mentioned. We hope, however, for better times in the future. I now propose the resolution.

Mr. SAMPSON HANBURY seconded the motion.

Mr. DRAKE thought the shareholders would agree, after what the Chairman had said, that the concern was managed with great care. The progress was not brilliant, but perhaps it was better for being gradual and safe. He was pleased to see that a further sum of £23,200 of terminable Mortgage Debenture Bonds had been paid off. The present was a very advantageous time for paying off debts, because well-established companies could borrow money at very cheap rates. He desired to know whether the £76,500 Preference shares was a perpetual or terminable charge. The

Digitized by Google

Preference shares afforded the measure of the public confidence in the undertaking, and he saw that these shares were quoted at about 50 per cent. advance on their issue price.

Mr. JEFFERIES thought that on the whole they might regard the report as of a congratulatory nature. He wished to ask whether in arranging the extension to Finsbury Circus there would be a subway, or any means of getting from their station to the Moorgate-street Station.

The CHAIRMAN: I am obliged to Mr. Drake and Mr. Jefferies for their kind remarks. The Preference shares are perpetual, but some of them have been issued at a premium, and if we issue any more they will command a very large premium. We are not paying much over 3 per cent. on this capital. We pay less than 3 per cent. for what we have lately issued of our Debenture stock in exchange for the Five per Cent. Bonds that fell due. There are still £54,800 of the terminable debentures to be paid off, but we can only pay them off as they fall in each half-year. As to the question of lighting, it was not simply a question of expense. A separate system for lighting the carriages would involve a second conductor along the line, and there are objections to a second conductor in the tunnels. We are endeavouring to get over this question of the lighting in a more economical way, and I hope before very long we shall be able to do something in that direction. The light is not bad, but I am quite sure it would pay this Company to have an exceedingly good system, as it would enable people to read their papers—and travelling into town is the only opportunity which many of our passengers have for reading. Many persons who might travel by our line now prefer to go on the outside of an omnibus, where they can have a good light. I hope some day to make ours the best lighted carriages on any railway in the country. A connection with Moorgate-street station is in contemplation. The advertising is included in the rents of property, and we have a considerable sum for this.

The motion was then unanimously adopted, and the dividends recommended were afterwards approved.

On the motion of Mr. DRAKE a vote of thanks to the Chairman and Directors was cordially agreed to.

The CHAIRMAN: I beg to thank you very heartily for the kind way in which you have received us to-day. I hope that we shall meet on a more satisfactory basis, as far as the dividend is concerned, on a future occasion.

National Telephone Company (Limited).

The sixteenth ordinary general meeting of this Company was held last Friday at the Cannon-street Hotel, under the presidency of Mr. James Staats Forbes

The SECRETARY (Mr. Albert Anns) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN then said: As far as I am personally concerned, the character of our report is a little disconcerting, for I am so much in the habit of dealing with bad reports that when I get a good one I do not feel quite at home. I trust that at starting you will all agree that this report is a satisfactory one. You will see that there is a substantial increase in our income in the half-year—and I must remind you that we are on this occasion dealing with half-yearly figures, whereas for a good period of our existence we have dealt with the figures only annually. The increase in the income of the past half-year to June 30th was £33,963, as compared with the income for the corresponding period of 1894. In the working expenses there is also a considerable increase, but not very much out of proportion to the increased business. The net result, after deducting the very large amount for royalties accruing to the Post Office under agreement, amounting to £35,263, is a profit balance of £151,703, which is an advance of £11,169 over the balance shown at the corresponding period of the previous year. Our business has progressed apart altogether from the results of the particular half-year, and you are already assured of a very large amount of additional money, for the rentals carried forward for unexpired terms of running contracts amount to £390 978, or an increase of £45,619. As I have said before, a contract beginning on the 1st of January and ending on the 31st of December comes into the accounts of the year; but if it begins on the 1st of February only 11 months come in, and the other month is carried forward to the benefit of the following year. In this way we have £390,978 in our possession in respect of services to be given beyond this half-year, and it is a very large sum. It is also one of the best indications we have of the steady progress of our business in volume, and, happily, year after year we show that the volume carries an additional profit. We propose to pay the accustomed dividends secured on the First, Second, and Third Preference shares, less income tax, and 5 per cent. on the Ordinary capital, free of income tax. At our last meeting Mr. Galbraith and other gentlemen expressed a very strong feeling that it would be very acceptable to the shareholders if the dividend were paid free of income tax. Well, there is no particular reason why it should not be, and if you determine that it must be we should not object to it under the circumstances of the Company; but we find on legal advice that we can only pay the dividend on the Ordinary shares free of income tax. The Preference shares have a preference on the income of the Company, and they are not entitled to and cannot legally be credited with anything more than their bond. Having exhausted the dividend claims on us for the half-year, we have a considerable available balance; and we propose, with your permission, to do with that what we have done before—carry it to the reserve fund to the extent of £35,000, leaving £3,288 to be carried forward. Going back to the working expenses, I may say that we have debited them to the fullest possible extent, with all reasonably proper charges, and if there has been an error at all, it has been, perhaps, in the right direction. We have written off more largely than in preceding years the item of depreciation. As regards the net income, it has been arrived at, for the first time, after charging interest out of revenue upon our large reserve fund, and that is in some sense doing what certain gentlemen have often suggested, arguing in favour of a liquid asset in your reserve. The reserve fund now stands in the balance sheet as follows: Reserved from profits £237,727, and premium account £35,189, together £272,900 in round figures. If you approve of our recommendation now, that amount will be swollen by the £35,000 from revenue. I hope that this is a matter which will meet meet with your approval. We are extremely satisfied on this side of the table with the statement of accounts, considering the unsettled position in which the Company stands in relation to Parliamentary committees and so forth. Before I leave the figures I should like to refer to capital account. We expended in the six months up to the 30th of June, on construction of exchange, trunk, and private lines, £149,935, and as I have had to explain before, and may repeat now, this business cannot be extended even to one subscriber without finding so many sovereigns to carry out what is called an installation, and that expenditure has to be incurred before you can collect any revenue. The number of these new lines erected during the half-year has been 4,194. As far as a new subscriber goes, his proportion of this charge is carried to capital account. That brings out an average sum of £35. 15s. per line, so you see the risk that we run. It costs us £35. 15s. to put every subscriber on our system before we can call on him for anything for the service we render. I have been listening to many fallacies of late about telephoning. Some people have been insisting that this is a business which can be done for nothing; that it costs nothing to erect the lines, and very little to conduct the business, and that therefore our moderate charge for the enormously valuable services we render is much too high. That all rests on absolute ignorance and fallacy. There is nothing so eloquent as figures, and our experience shows from year to year how much you have to pay the piper before you can enjoy the dance. Well, that is what it cost us this half-year—on the average £35. 15s. for every subscriber; but I must subdivide that, lest any of you should go away under a misapprehension. Averages are very useful, but they are sometimes a little illusory. London is a place quite apart and special; there is only one London in any sense, and that is true more than anything else I know of with the telephone system. There is only one place like London which has to be telephoned in all the world. We have erected in London 557 subscribers' lines, and they have cost us £55,371, representing an average cost of £99. 8s. each; but that embraces a contribution to a great work which has been going on in London in the half-year in connection with the repair of a primitive error. We are asked why we did not metallic-circuit London, and we are told how short-sighted and wrong it was not to have done so and what an abominable system we have in consequence. Well, people live and learn, and this is a business in connection with which people have had to learn a great deal. On its initiation the single line was all that was sufficient, and of course it was much less costly and complex, and we adopted it; but it ceased to be good under certain circumstances, and those circumstances have arisen in London and all great centres. An enormous amount of telephone work is done in these places, where there has likewise been a growth of new disturbing causes in the way of other electric currents. That has entirely altered the condition of telephoning as compared with what it was at the period when it was first conceived and carried out. We are so persuaded of that by experience that we are spending an enormous sum of money in order to repair this mistake, and we have been metallic-circuiting London. That work has been going on quietly—almost imperceptibly—for several years, but happily it is now approaching completion. I daresay that by the end of the year the whole of London will be metallic-circuited, at enormous cost, and what is almost worse for us, at the expense of great derangement of the whole machinery of the Company from time to time, to the serious annoyance of many of our subscribers. This, however, is an incident inseparable from that great change, but when it is effected I have no doubt that two things will follow—a great diminution in all legitimate ground of complaint, and a much more efficient service; and I believe that it will also cause a vast spring in the number of telephonic subscribers. That is also going on in some other great centres—Manchester, for instance—and no doubt it will have to be carried out in all centres where telephoning is assuming large proportions. We are told that the large telephonic business in Berlin is carried on in an exemplary manner, and at a cost of scarcely anything; but neither statement is quite true. There is a very minute proportion of that business which is not performed on a single wire, and knowing Berlin very well I have often asked myself the question whether the even way in which the business is conducted there does not arise from local circumstances. Every subscriber in London thinks that he has got the fee-simple of the whole apparatus at his command—that he alone has to be served. He forgets that there are thousands of people, especially during the pressure of the busy part of the day, who have a common user of the system with himself. I am, however, told by some of our operators—ladies, too—that the language which is sometimes used, because a hot-tempered gentleman in a hurry is kept a minute or two before he is placed in communication, is of a very strong character. This arises from a misconception of the contract which the hot-tempered man has entered into, which is not for the sole possession, but for common user. In Berlin everything is regulated. The whole German people have been so drilled and regulated that they know how to wait; and notoriously—it has passed into a proverb—everything comes to the man who knows how to wait—even the telephone (laughter). The expenditure in other places in the half-year on the construction of exchange, trunk, and private lines was £94,564, which means an average expenditure per subscriber of £26. Therefore, under the most favourable circumstances, taking the various places served, it is a good round sum which has to be expended in order to enable you to start a subscriber. The average subscription now is a little over £9 for the whole of our business, so that we have to spend £26 on the chance of obtaining from a gentleman £9 a year for three years, giving him all this time the service he requires. I do not think that anyone who is cognisant of these facts—not fancies—would be wise to put his money into a competing business with us

Digitized by Google

on the theory that every subscriber might be installed for about £10 or £15, and be worked for nothing. That is all I will say on the accounts, unless you choose to ask me any questions. I now come to paragraph 7 of the report, which is very interesting. In regard to the matter dealt with in that paragraph I will not say that we embraced the occasion, or that we were extremely sweet upon it, but we were face to face with an alternative—either to agree with the enemy in the gate, and that promptly, or fight him; and it struck us that a fight with the Government and the Post Office would not be a very wise proceeding. Therefore, like all people of experience, with their tempers well in hand, we bowed to the inevitable, and made the best terms we could, and I believe that they will prove to be extremely good terms. The relative value of them will, of course, turn on the loyalty of both parties to the contract. If the Government and the Post Office authorities are as loyal as we are—and there is not the slightest reason to doubt that they will be—then I will venture to say that for the revenue of the country, for the efficiency of the telephone service, for the public interest, and for our own interest, it will be the best combination that could have been made, because the Post Office are enabled to take risks in respect of the extension of this system which we should not have been inclined to take, but of which we shall have the benefit, while we shall be left free to develop what is our more special business—the conduct of this exchange work in the great areas. There is a great deal less risk in this work than in the expenditure necessary on great trunk lines. That is what the Government have to do, and it is very wise of them, because a Government has to consider the indirect benefits accruing to the community as well as the benefits conferred on particular people who use a particular commodity. We have to consider, on the other hand, what is best for us as people working for profit and loss, while the Government can afford to think of the advantages to the community of what they may do. The heads of this Agreement were signed more than two years ago, but they have been necessarily subjected to a great deal of discussion. No man could have been more straightforward, more considerate, or more inclined to act with entire fairness in this matter than the late Postmaster-General, Mr. Arnold Morley—and when I say Mr. Arnold Morley I mean every official of the Post Office, who are gentlemen of great knowledge and experience in dealing with these matters. They have Post Office views, and they do not go as fast ahead as we, but they are not such free agents, and they have not a terrible body of shareholders to meet to urge them on. Moreover, the Post Office cannot spend as much, perhaps, as they would like to, as they have to deal with another Department called the Treasury. We, however, can adapt this business more readily and rationally to the great wants of the public than any Government department whatever. Ours is a commercial undertaking, and theirs is only a semi-commercial undertaking tramelled with terrible official drags. I remark that of the Post Office because that Department is occasionally rudely assailed in the House of Commons and elsewhere, and they are charged with not being sufficiently prompt to meet the demands of the public or the wants of certain reforming faddists. In virtue of this Agreement we have made considerable sacrifices, for I have no doubt that if we had been allowed to go on under the old arrangement, we should have made more substantial advance in the development of the telephone system, because the expansion of the exchange business is considerable, treated merely as local business, but assisted by through communication from centre to centre there is an additional incentive for people to get on to exchanges, and we have found by experience that our business is a great deal hampered, particularly in the great industrial centres, by the paucity of trunk wires. We are no longer allowed to erect them, and our unhappy position is this—that the grumbling Briton does not discriminate. We are the people he pays his money to, and he therefore complains to us. No doubt the Post Office do not put up the trunk wires as fast as the public want them, but all that will come in time. This Agreement, I may say, was laid on the table of the House of Commons, and it was taken up and criticised by certain persons. In order to prevent anyone from saying that the Agreement was not perfectly fair and above-board, or that there was any desire to conceal it, it eventually, with the Company's consent, was referred to a Special Committee, and those who are fond of blue books will very shortly be favoured with the issue of the proceedings of that Committee. They sat a considerable time and met on several occasions, very eminent gentlemen being members of it, and the late Postmaster-General being the Chairman. We had an opportunity before that Committee of hearing a great deal, and I think that every possible thing that could be alleged against the Company was alleged, and in a considerably florid way. We were the defendants, and they took the plaintiffs' case first, and there was a constant accumulation of evidence as to what we ought to do but did not do, and as to our overbearing conduct, our extravagant charges, and our voracious appetites. However, our turn came, and then we gave the facts, the figures, and the arguments. We contrasted what we were doing with what was being done by the examples set before us. Wherever there was any parity of comparison it was made. If a small village in Holland, where some amateurs, in a sort of joint-stock mutual admiration telephonic society, found the money and worked it for nothing, and made 1 or 2 per cent., was the standard put before us, well and good; but such a comparison was not a fair one. When, however, we came to Berlin, the great cities of the Continent, and especially America, it was all one way, and we made out that when the facts were riddled we were cheaper and as efficient as any telephone service with which comparison could be fairly made; and, what is more, that the proportion of telephone subscribers in England and the user of the telephone by them bore favourable comparison with that of anywhere else. It is very important that our own proprietors, at all events, should have their minds put at ease, and I had better, therefore, tell you where this matter has got to. This is the report of the Committee, and the reference to the Committee is this: "To consider and report whether the provision now made for the telephone service in local areas is adequate; and whether it is expedient to supplement or improve this provision either by the granting of licences to Local Authorities or otherwise." This Committee sat a great many times, and heard a vast amount of evidence; and then came a disturbing cause—the Dissolution, and we poor creatures, instead of being relieved of the tension of anxiety which had hung over us, were left with this report of the Committee: "Your Committee have examined numerous witnesses upon the matter referred to them, and have completed their evidence, but have not, in view of the approaching Dissolution of Parliament, had sufficient time to consider their report. They have therefore agreed to report the evidence they have taken to the House, and to recommend that a committee on the same subject be appointed in the next Session of Parliament to consider and report upon the evidence already taken, and, if necessary, to take further evidence." I do not know what is going to happen. I am glad to say, from one point of view, that the majority of the members of that Committee—who, at all events, whatever their feelings were, concealed them—have been returned to Parliament. I am sorry to say that four or five esteemed friends of my own, who were not quite as wise in concealing their feelings as to the enormities of this Company, have not been returned to Parliament; but I do not think that their feelings towards this Company could have operated against them at the elections. However, out of the 15 members who sat on the Committee 10 or 11 have gone back to Parliament; and I hope that they will really finish this inquiry, because until they do we do not know where we are. I should like now to anticipate your perusal of the evidence which was given before the Committee by mentioning one or two facts. This is a little statement which we handed in in order to answer volumes of accusations which were made against us. It is the development of the National Company up to April, 1895. The number of towns and places supplied at that date was 537, the number of exchanges open was 593, the number of subscribers' lines was 75,216, and the number of telephones in use was 86,032. The present ratio of effective calls per annum is 139,639,032. Everyone seems to want to speak to someone else. It may be once or twice before he is put into communication. This means the operation of calling, waiting for a reply, calling again, and waiting for another reply without success; but when you have succeeded in giving Mr. A. the great advantage of talking to Mrs. B., that is an effective call, and the number of these calls per annum is 139,000,000. An effective call means at least two messages: "How do you do?" "Very well, thank you." That is a message. "Will you come to dinner?" "Cannot; already engaged." That is another message. There may be half-a-dozen of them, and there are, as a matter of fact, several of these messages; but we do not count them, but only these millions of messages on the basis I have mentioned to you. That is the measure of this wonderful service. People cannot comprehend what it means, although they are beginning to do so now. The average annual payment per line throughout the country is £9. 2s. 2d., and the average cost to subscribers per message is 0·58 of a penny. Now, if any of you have certain correspondents on the telephone what a delight it is to be able to call and talk to them for 0·58 of a penny per message! But only fancy—urgent business, matters of life and death, matters of credit, matters of great social and commercial convenience being administered safely and promptly for 0·58 of a penny per conversation! The estimated minimum average number of words per message is 100, so that for 0·58 of a penny you can have 100 words, whereas 100 words by telegraph would cost you 4s. 2d. That is one way of putting it, and it is astonishing. I watched the faces of the Committee when I read that evidence, and I saw, or I thought I saw, as regards some of the members, that it dispelled all the nonsense that had been talked about the scandalous extravagance of our charges. I will put it in another way to make it intelligible and popular. It appears that the working man is suffering terrible torture because he cannot use the telephone. My natural inquiry on hearing that was, How much does he use the telegraph? He does not use it at all. Then there is the small tradesman: he complains because he cannot compete with the great capitalists, for the reason that the Telephone Company will not let him. Well, we work it out in this way: Average annual payment, £9. 2s. 2d.; average per week, 3s. 6d.; average per day (Sunday included), 6d. Therefore the poor tradesman must be very poor indeed, and have a very small business, if he cannot afford this wonderful implement at 6d., which is about the price of sweeping out his shop. Every subscriber can have the use of the telephone by day, and in most places by night, for the price of a sixpenny telegram, and, as I have just said, whereas 100 words would cost 4s. 2d. by telegraph, the average cost per message with the minimum of 100 words by telephone is 0·58 of a penny. I hope you will not think I have wasted your time by putting you into possession of these facts. Sometimes our friends of the Press speak of us rather under a misapprehension, but I hope they will do us the justice of contributing somewhat to dispel the aspersions which they have assisted in spreading regarding our extortion. I need not trouble you, I think, with any more details about this. We hope, as we say, that this question that has been submitted to a Parliamentary Committee will be speedily determined, and then we shall know where we are, and whether we are to be competed with in every centre by the local County Council or any other modern institution which has been created for the purpose of interfering with everyone else. The business itself will not admit of competition. It is essentially a monopoly by its very nature, and is part of the Post Office business of the country; it can be done much better in the hands of one company than by means of competition, as that would mean splitting people up into two or three camps. In one or two places we serve, people have had to pay subscriptions to two companies in order to get the advantage of the telephone service. With respect to the resignation of Lord Balfour of Burleigh, he has become a Cabinet Minister, and he found it consistent with his duty to resign his position in this Company. He was a man of considerable position and of great business capacity, and he is a perfect gentleman. During the time he was with us his services were invaluable, because he was not only a first-rate man of business and a diligent attendant in connection with the detailed work of our committees, but he was an agreeable mediator. If he thought you were wron

Digitized by Google

he had the most charming way of telling you so, and driving it home with the most forcible but pleasant arguments. He was therefore of great service to a Board like ours, where we are all strong men and fond of our own opinions. Four of the Directors retire by rotation—Mr. Eli Heyworth, Mr. Samuel Herrick Sands, Col. R. Raynsford Jackson, and myself. Col. Jackson has unfortunately been ill for a long while, and when it came to the question of his offering himself for re-election, he found it inconsistent with his duty to pretend to be able, with any satisfaction to himself, to continue further to serve you, and he therefore sent us his resignation.—The Chairman concluded by moving the adoption of the report and accounts and the payment of the dividends recommended.

Mr. ELI HEYWORTH seconded the motion.

Mr. HARRIS complained of the service given by the Company, and asserted that many of the subscribers had received very bad treatment.

Mr. LEAKE congratulated the Directors on the very satisfactory report which they had been able to submit on the present occasion. He referred to the item on the debit side of the account of "Redemption of Four and a-Half per Cent. Debenture Stock, £121,295," and said that it could not be considered an asset.

The CHAIRMAN, in reply, stated that the amount in question represented in a concrete form the advantage which the Company would gain eventually by reducing the interest on the debenture debt. He was glad that the action of the Directors, in adding to the reserve fund the interest on the fund, was approved. The main trunks which the Post Office were laying to connect the capital with other places—Edinburgh, Dublin, and elsewhere—would be connected with the Company's subscribers, who would be able from their places to despatch messages to these distant places. Mr. Harris, who was the proprietor of one share and a subscriber, had given the Company a considerable amount of trouble by the numerous complaints which he had addressed to them, many of which were unreasonable. He then put the motion, and it was carried. He afterwards stated, with regard to the two vacancies on the Board caused by the retirement of Lord Balfour of Burleigh and Col. Jackson, that the Directors had given much consideration to the question of their successors, and they had elected Sir Henry Calcraft, who was for many years Permanent Secretary of the Board of Trade, and Lord Harris, who had recently returned from Bombay, of which he had been Governor. He hoped that these appointments would be acceptable to the proprietors, whom they would have preferred consulting on the matter had there been time. It was, however, necessary for the vacancies at the Board to be filled up promptly: but he would ask them to express, informally, by a show of hands, whether they approved the selection which the Board had made. Having submitted the question to a show of hands, he thanked them, remarking that the election of the gentlemen in question appeared to be generally satisfactory to the shareholders.

The retiring Directors were then severally re-elected; and the auditors, Messrs. Welton, Jones and Co., were also reappointed.

Votes of thanks to the Chairman and Directors, and to the General Manager (Mr. W. E. L. Gaine), the Secretary (Mr. Albert Anns) and the Engineer-in-chief (Mr. D. Sinclair), brought the proceedings to a close.

Chili Telephone Company (Limited).

The annual general meeting of this Company was held on Tuesday at Winchester House, under the presidency of Mr. George Keith (Chairman).

The SECRETARY (Mr. Edmund Petley) read the notice calling the meeting.

The CHAIRMAN said: Gentlemen, I suppose you will take the report as read. You will notice mention of the death of Mr. Greenwood, one of the first Directors of the Company and its late Chairman. From the commencement of the Company until his decease he devoted a great deal of his time and experience to its interests, and his loss is much regretted by all who knew him. The report deals with the accounts so fully as to leave very little for me to say in submitting them for your approval. You will be pleased to see that the business of the Company shows a good improvement over that of the previous year, and the result is so far satisfactory as to enable the Board to recommend the payment of a dividend of 2½ per cent., free of income tax, on the shares. This result is all the more satisfactory as it is the outcome of a year which has been very adversely affected by the depression of business generally all over Chili, by exceptional expenditure, and by the extreme lowness of exchange. The bad state of business generally caused not a few subscribers to retire. During the year 704 new subscribers were brought in, and 676 gave up their telephones. This large movement entailed not only the cost of bringing in new subscribers to make up for the ceased ones, but also a considerable loss of revenue by laying idle many wires which have not yet been utilised. Yet with all this loss the gross receipts, as you will see by the report, improved about 10 per cent. The exceptional expenditure incurred by overhauling some of the trunk lines, and putting them and other parts of the property in efficient order, increased the expenses about 12 per cent., and it is very satisfactory to know from our Manager that this expenditure is not likely to occur again, at least for some considerable time. The mean average rate of exchange by which the net income in Chili was reduced into sterling, was lower than in any previous year. The exchange fell to a minimum of 10¾d. in May, 1894, and after fluctuating under the shilling for nearly three-quarters of the year, gradually rose in the last quarter to 16⅞d., in consequence of the passing of the Conversion Bill by the Chilian Legislature. Notwithstanding these adverse circumstances, the net profit for the year amounts to £6,013, as compared with £3,528 of the previous year, a gain of £2,485. During the year some important extensions have been made in the way of country and suburban lines, which have added considerably to the value of the property, and the capital expenditure has been much lessened by the subscribers of these lines having given very favourable terms to the Company for their erection in order to obtain telephone communication. The prospects of the Company for the current year have been brightened considerably by the passing of the Conversion Bill and the adoption by Chili of a gold standard. The value of the gold dollar now introduced is about 18d., and if this conversion be carried to a successful issue, as we hope it will be, there is every prospect that the exchange will vary little from the present rate of 17d., and that we shall be freed from all the difficulties arising from its recent fluctuations and depression. Lately a good deal has been said in this country about the telephone service, and not a few, principally those who know little about it, think it ought to be cheaper and better. We have some of those people out in Valparaiso, and they are attempting to carry out their ideas, but whether they will succeed or not remains to be seen. Our Manager says their chances of success are small, and their attempt will most probably end in utter failure. In any case I should think that the prospects of those who may be induced to supply the money would be anything but bright, and you may rest assured that every endeavour will be made to protect the interests of our Company. With these remarks I beg to move—

"*That the report of the Directors, with the statement of accounts to March 31, 1895, now presented to this meeting, be approved and adopted.*"

Mr. FRANK W. JONES seconded the resolution, which was carried unanimously, without discussion.

The CHAIRMAN then proposed the following resolution:—

"*That a dividend of 2s. 6d. per share, as recommended by the Directors, be and is hereby declared, and that the same be payable at the Company's bankers on and after July 31st, free of income tax.*"

The Hon. F. ERNEST ALLSOPP seconded the resolution, and it was passed.

The CHAIRMAN moved the re-election as a Director of Mr. Frank W Jones.

Mr. ALEX. HENDERSON seconded, and it was carried.

Mr. ALEX. WHITTET moved, and Dr. JOHNSON seconded, the reappointment of the retiring auditor, Mr. Thomas A. Welton, and it was agreed to.

Mr. HENDERSON, in moving a vote of thanks to the Chairman, the Board of Directors, and the staff generally, expressed his satisfaction at the declaration of the dividend, although small in amount. He noticed it was not from want of revenue that the distribution was only 2½ per cent. this year, but was owing to the low rate of exchange, which, of course, was one of those things no Directors could control. As there was every probability of the exchange keeping up to 17d. or 18d., it meant that they would receive a larger dividend next year, if the Company's earnings remained at the present rate.

Mr. WHITTET seconded the proposition, and it was unanimously passed.

The CHAIRMAN briefly acknowledged the vote of thanks, after which the meeting terminated.

Edison and Swan United Electric Light Company (Limited).

The annual meeting of this Company was held on Monday at the Cannon-street Hotel, Mr. James Staats Forbes (Chairman) presiding.

The SECRETARY (Mr. H. Charles Gover) read the notice convening the meeting.

The CHAIRMAN said: I suppose we may take the report and accounts as read, they having been circulated among you. This report and accounts contain the results of the second year of our working in the open. What I mean by that is that our patents expired at the end of the first three months of the previous year, and then we were immediately subjected to what we fully expected—namely, rather severe competition from a great many quarters, including our German friends over the water, who are pretty astute and persevering. As I had occasion to remark the proprietors at the last meeting, a public company is, no doubt, an excellent institution, and the prescription under which it is governed is excellent too, yet I am not quite sure that prudent tradesmen, in the face of very acute competitors, reveal to the outside world all that they themselves know. It is not in the interest of the shareholders or partners of this concern that the affairs of the partnership should be picked to pieces too much in detail, so that the very things our competitors wish to learn they may learn in the only way they can do so, except by induction from our accounts. That was a principle which seemed to meet with the commendation of the meeting when I enunciated it last time, and, of course, competition having become keener during the second year of our working in the open, the necessity, if it existed before, of being discreet is more urgent now than then. I think it really comes to this: you will have to extend to your Directors, or the managers of your property, whosoever they may be at any particular moment, a good deal of your confidence, and believe that their daily knowledge of the circumstances of the business, as varied from day to day by circumstances which are always varying, will enable them, with prudence and discretion, to secure your interests, without putting on them the necessity of publishing in too great detail the many items which make up the business. And you will have to be satisfied, perhaps, with yourselves, as men of common sense in business, drawing from the figures we present to you the general conclusions that under the circumstances the business is satisfactory. Of course, I need hardly tell you that having been protected for a good many years we were in a very advantageous position during that period. We were masters of the situation. We could fix our own prices and we did receive very large prices for our wares. As the time approached for our patents to expire we made arrangements, with reasonable prevision, for meeting what was probable to arise—a severe competition the moment the patents had run out, and therefore we toned down our prices by degrees, and awaited the results of the nine months' working of the previous year with a good deal of anxiety. Well, the results of the year
